# Software Implementation of the IEEE 754R Decimal FloatingPoint Arithmetic Using the Binary Encoding Format 

Marius Cornea, Cristina Anderson, John Harrison, Peter
Tang, Eric Schneider, Evgeny Gvozdev, Charles Tsen
June 25, 2007

## Decimal Floating-Point Applications

- Applications that involve financial computations: banking, telephone billing, tax calculation, currency conversion, insurance, accounting in general
- Current feedback indicates that decimal computations take a small fraction of the total execution time
- No indication that scientific computation will migrate to decimal arithmetic in the near future
- IEEE 754R addresses the need for good quality decimal arithmetic, and defines three basic formats: _Decimal32,
_Decimal64, _Decimal128

## Decimal Floating-Point Applications

- Example of decimal floating-point computation, performed with the Intel IEEE 754R Decimal FloatingPoint BID library from GCC 4.3:

```
float f1 = 7.0, f2 = 10.E3, f3;
    Decimal32 d1 = 7.0, d2 = 10.E3, d3;
f3 = f1 / f2; f3 = f2 * f3;
printf ("f3 = 0x%8.8x = %fln", *(unsigned int *)&f3, f3);
d3 = d1 / d2; d3 = d2 * d3;
printf ("d3 = 0x%88.8x = %fln", *(unsigned int *)&d3, d3);
f3 = 0x40dfffff = 7.000000 (6.9999997504 with other compilers)
d4 = 0x32000046 = 7.000000
```

## IEEE 754R Decimal Floating-Point Encoding Methods

- For example _Decimal64 numerical values are:
$\mathrm{v}=(-1)^{\mathrm{s}} \cdot$ significand $\cdot 10^{\text {exponent }}$
(up to 16 digits; exp. range $=[-383,384]$, bias $=398$ )
- Decimal Encoding Method: based on the Densely Packed Decimal (DPD) method - up to three decimal digits are encoded in 10-bit fields named declets (non-linear mapping)
- the encoding is "s G E T":
- $s=1$-bit sign
- $G=5$-bit combination field: encodes the leading decimal digit and the top two exponent bits
- $\mathrm{E}=8$-bit exponent field - the lower 8 bits of the biased exponent
- T = 50 lower bits of the coefficient (significand), consisting of 5 declets

## IEEE 754R Decimal Floating-Point Encoding Methods

- Binary Encoding Method: based on Binary Integer Decimal (BID); the coefficient C (significand, scaled up) is a binary integer
- the encoding is "s E C 52-0 $^{\prime}$ " if the coefficient $\mathrm{C}=\mathrm{d}_{0} \mathrm{~d}_{1} \ldots \mathrm{~d}_{15}$ represented as a binary integer fits in 53 bits
- the encoding is "s $11 \mathrm{E} \mathrm{C}_{50-0}$ " otherwise, and $\mathrm{C}_{53-51}=100$
- The biased exponent field $E$ takes 10 bits
- The BID format does not require a costly conversion to/from binary format on binary hardware, which matters especially when the decimal arithmetic is implemented in software

## Rounding Binary Integers to a Given Number of Decimal Digits

- Occurs in addition, subtraction, multiplication, fused-multiply add, and conversions that use the BID encoding
- Example: round the decimal value
$C=1234567890123456789$
stored as a binary integer, from $q=19$ to $p=16$ decimal digits; need to round off $x=3$ digits
- Straightforward method
- Better: multiply by $10^{-3}$
- If $\mathrm{k}_{3} \approx 10^{-3}$ is calculated with sufficient accuracy and rounded up, then
floor $\left(C \cdot k_{3}\right)=1234567890123456$
with certainty

## Rounding Binary Integers to a Given Number of Decimal Digits

- Method 1: Calculate $\mathrm{k}_{3} \approx 10^{-3}$, y -bit approximation of $10^{-3}$ rounded up

$$
\text { floor }\left(\mathrm{C} \cdot \mathrm{k}_{3}\right)=1234567890123456=\text { floor }\left(\mathrm{C} / 10^{3}\right)
$$

- Method 1a: Calculate $h_{3} \approx 5^{-3}$, y-bit approximation of $5^{-3}$ rounded up

$$
\text { floor }\left(\left(C \cdot h_{3}\right) \cdot 2^{-3}\right)=1234567890123456=\text { floor }\left(C / 10^{3}\right)
$$

- Method 2: Calculate $h_{3} \approx 5^{-3}$, y-bit approximation of $5^{-3}$ rounded up floor (floor $\left.\left(\mathrm{C} \cdot 2^{-3}\right) \cdot \mathrm{h}_{3}\right)=1234567890123456=$ floor $\left(\mathrm{C} / 10^{3}\right)$
- Method 2a: Calculate $h_{3} \approx 5^{-3}$, y-bit approximation of $5^{-3}$ rounded up floor (floor $\left.\left(C \cdot h_{3}\right) \cdot 2^{-3}\right)=1234567890123456=$ floor $\left(C / 10^{3}\right)$

## Basic Property for Decimal FP Arithmetic on Binary Hardware

- Property 1: Let $\mathrm{q} \in \mathrm{N}, \mathrm{q}>0, \mathrm{C} \in \mathrm{N}, 10^{\mathrm{q}-1} \leq \mathrm{C}<10^{\mathrm{q}-1}$, $x \in\{1,2,3, \ldots, q-1\}$, and $\rho=\log _{2} 10$.

If $y \in N, y \geq$ ceiling $(\{\rho \cdot x\}+\rho \cdot q)$ and $k_{x}$ is a $y$-bit approximation of $10^{-x}$ rounded up, i.e.

$$
k_{x}=\left(10^{-x}\right)_{R P, y}=10^{-x} \cdot(1+\varepsilon), \quad 0<\varepsilon<2^{-y+1}
$$

then

$$
\text { floor }\left(C \cdot k_{x}\right)=\text { floor }\left(C / 10^{x}\right)
$$

## Correction Step for Rounding to Nearest

- Property 2: Let $q \in N, q>0, x \in\{1,2,3, \ldots, q-1\}$,

$$
\begin{aligned}
& C \in N, 10^{q-1} \leq C<10^{q}-1, C=10^{x} \cdot H+L, \\
& H, L \in N, H \in\left[10^{q-x-1}, 10^{q-x}-1\right], L \in\left[0,10^{x}-1\right], \\
& f=C \cdot k_{x}-\text { floor }\left(C \cdot k_{x}\right), \\
& \rho=\log _{2} 10, y \in N, \\
& y \geq 1+\operatorname{ceiling}(\rho \cdot q), \\
& k_{x}=10^{-x} \cdot(1+\varepsilon) \quad 0<\varepsilon<2^{-y+1}
\end{aligned}
$$

Then the following are true:
(a) $\mathrm{C} \cdot 10^{-x}=\mathrm{H}$ iff $0<\mathrm{f}<10^{-\mathrm{x}}$
(b) $\mathrm{H}<\mathrm{C} \cdot 10^{-x}<(\mathrm{H}+1 / 2)$ iff $10^{-\mathrm{x}}<\mathrm{f}<1 / 2$
(c) $C \cdot 10^{-x}=(H+1 / 2)$ iff $1 / 2<f<1 / 2+10^{-x}$
(d) $(H+1 / 2)<C \cdot 10^{-x}<(H+1)$ iff $1 / 2+10^{-x}<f<1$

## Reducing the Length of Constants $\mathrm{k}_{\mathrm{x}}$

- Property 2 also helps reduce the length of some of the constants $\mathrm{k}_{\mathrm{x}}$
- Reduce the accuracy of $k_{x}$ one bit at a time, and verify that for $\mathrm{H}=10^{q-x}-1$ :
(a) $H \cdot 10^{x} \cdot k_{x}<H+10^{-x}$
(b) $\left(H+1 / 2-10^{-x}\right) \cdot 10^{x} \cdot k_{x}<H+1 / 2$
(c) $(H+1 / 2) \cdot 10^{x} \cdot k_{x}<H+1 / 2+10^{-x}$
(d) $\left(H+1-10^{-x}\right) \cdot 10^{x} \cdot k_{x}<H+1$
- For example $\mathrm{k}_{3}$ is reduced from $\mathrm{y}=65$ to $\mathrm{y}=62$ bits

## Software Implementation of the IEEE 754R Decimal FP Arithmetic

- The values $k_{x}$ for all $x$ of interest are pre-calculated and are stored as pairs ( $\mathrm{K}_{\mathrm{x}}, \mathrm{e}_{\mathrm{x}}$ ) with $\mathrm{K}_{\mathrm{x}}$ and $\mathrm{e}_{\mathrm{x}}$ positive integers, and $\mathrm{k}_{\mathrm{x}}=\mathrm{K}_{\mathrm{x}} \cdot 2^{-\mathrm{ex}}$.
- The algorithms and operations presented here represent the core of a generic implementation in C of the IEEE 754 R decimal floating-point arithmetic
- Test runs for several hardware configurations, operating systems, compilers, little/big endian, build options

## Software Implementation of the IEEE 754R Decimal FP Arithmetic

- Several decimal floating-point operations, in particular addition, subtraction, multiplication, fused multiply-add, and most conversions could be implemented efficiently using operations in the integer domain
- An important property is that when rounding the exact result to $p$ digits, the information necessary to determine whether the result is exact (in the IEEE 754 sense) or perhaps a midpoint, is available in the product $\mathrm{C} \cdot \mathrm{k}_{\mathrm{x}}$ itself
- For division and square root, the algorithms are based on scaling the operands so as to bring the results into desired integer ranges, in conjunction with a few floatingpoint operations and one or two refinement iterations

Example: Decimal floating-point multiplication with rounding to nearest using hardware for binary operations. From $\mathrm{n} 1=\mathrm{C} 1 \cdot 10^{\mathrm{e} 1}$ and $\mathrm{n} 2=$ $\mathrm{C} 2 \cdot 10^{\mathrm{e} 2}$ the product $\mathrm{n}=(\mathrm{n} 1 \cdot \mathrm{n} 2)_{\mathrm{RN}, \mathrm{p}}=\mathrm{C} \cdot 10^{\mathrm{e}}$ is calculated.

## Software Implementation of the IEEE 754R Decimal FP Arithmetic

- Mixed-format floating-point operations, e.g. with operands of precision NO and result of precision $\mathrm{N}(\mathrm{NO}>\mathrm{N})$, are replaced by:
- similar, existing operation with operands of precision N0 and result of precision N0
- conversion from precision N0 to precision N
- logic to avoid double rounding errors
- Conversions between binary and decimal floating-point formats
- There is a finite, and relatively small number of (decimal, binary) exponent pairs that can occur in conversions
- For each pair use continued fractions to show that the relative error when a binary floating-point number is approximated by a decimal one (or vice-versa) for inexact conversions, has a lower bound which sets an upper bound on the intermediate precision needed to achieve correct IEEE conversion

## Performance Results - Clock Cycle Counts for a Subset of Decimal FP Arithmetic Functions (Intel Xeon 5100)

| Oper. | Min | Max | Med |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| add64 | 14 | 140 | 80 | Operation | Min | Max | Med |
| mul64 | 22 | 140 | 40/130 | bid64_to_bid128 | 8 | 12 | 8 |
| fma64 | 61 | 307 | 200 | bid128_to_bid64 | 125 | 174 | 145 |
| div64 | 58 | 269 | 170 | dbl_to_bid128 | 123 | 375 | 375 |
| sqrt64 | 35 | 192 | 180 | bid128_to_dbl | 160 | 185 | 160 |
| add128 | 80 | 224 | 150 | int64_to_bid128 | 5 | 5 | 5 |
| mul128 | 121 | 655 | 550 | bid128_to_int64 | 31 | 138 | 121 |
| fma128 | 299 | 1036 | 650 | bid64_quiet_less | 31 | 69 | 34 |
| div128 | 157 | 831 | 550 | bid128_quiet_less | 8 | 114 | 60 |
| sqrt128 | 227 | 947 | 900 |  |  |  |  |

## Conclusion

- Beta version available for download at http://www3.intel.com/cd/software/products/asmona/eng/219861.htm
- Next release in July 2007
- Opportunity for improving performance exists
- Possible future work:
- Implement optional parts of IEEE 754R
- Implement specific operations required by C/C++ Standards TRs on Decimal Floating-Point Arithmetic
- Optimize
