Abstract. This paper presents a framework for specifying and verifying distributed real-time object-oriented systems. An earlier paper [18] introduced a process calculus for describing distributed objects using local clocks. It was based on synchronous communication and thus could not sufficiently model asynchronous communication in distributed systems. In this paper we propose a new process calculus with the ability to express asynchronous message passing, communication delay, and delayed processing. It can describe temporal and behavioral properties of distributed real-time objects. Based on the new calculus, we develop a verification method by means of algebraic order relations. The relations are speed-sensitive and can decide whether two distributed real-time objects are behaviorally equivalent and whether one of them can perform its behaviors faster than the other. They offer a suitable method for proving the correctness and reusability of real-time objects in asynchronous communication settings. Some examples are shown to demonstrate the calculus and the relations.

1 Introduction

The notion of concurrent object-oriented computation [22] provides a powerful method for designing and developing distributed systems. This is because objects are logically self-contained active entities interacting with one another through message passing while in distributed systems, processors cooperate by sending messages over communication networks. However, these networks have communication delays because of geographic distance, communication bandwidth, and communication protocol overhead. The delay is often non-deterministic and seriously affects the timing of message arrival. Also, for efficiency reasons, communication among remote processors is asynchronous instead of synchronous, although asynchronous communication has its own unpleasant non-deterministic aspects. This is because in synchronous communication the sender must be

blocked for at least the round-trip time of the message, including communication delay.

Therefore, delay and asynchrony in communication create serious difficulties in the design and development of distributed systems, even if these systems are based on the object-orientation concept. To construct correct programs for distributed real-time systems, we need to analyze the influences of delay and asynchrony on the behavioral and temporal properties of the systems. In earlier papers [17, 18] the authors introduced timed extended process calculi, called *RtCCS* and *DtCCS*, for real-time concurrent and distributed object-oriented computing. Unfortunately, these calculi were based on synchronous communication and thus could not provide any general framework for asynchronous interactions among distributed objects.

In this paper we address this problem and propose a new framework of specification and verification for distributed real-time object-oriented systems with these features. The framework consists of two parts: a description language and a verification method for distributed real-time object-oriented systems. The language is formulated as a process calculus [2, 11, 12], because the powerful expressive capability of process calculi allows many features of concurrent objects to be modeled naturally [10, 16]. For example, objects can be viewed as processes; interactions among objects can be seen as communications; and encapsulation can be modeled by the restriction of visible communications. However, ordinary process calculi are based on synchronous communication and lack the notion of time. Therefore, in this paper we develop a new timed extended calculus, called *TACS* (*Timed calculus for Asynchronously Communicating Systems*), with the ability to express communication delay, asynchronous message passing, and delayed processing. It allows us to describe the temporal and behavioral properties of remotely located real-time objects and their asynchronous interactions with communication delay.

Our verification method is formulated on the basis of algebraic relations over objects described in the language. In asynchronous communication settings, a sender object needs only to deliver messages given in its behavioral specification to its receiver objects at *earlier* times than those specified in its temporal specification. It is very convenient to provide a verification method which decides whether or not two objects can send and receive the same messages and whether or not one of them (e.g., an implementation of an object) can perform faster than the another (e.g., the specification of the object). Also, we have many occasions to replace a slower object in a system with a faster object. In such a reconstruction, we need to guarantee that the slower object can really be replaced by the faster object without altering the behavioral properties or lowering the performance characteristics of the whole system. Therefore, we define algebraic order relations which distinguish between behaviorally equivalent objects performing at different speeds. The relations allow us not only to compare two distributed real-time objects with respect to their performances but also to prove that faster objects can behaviorally replace slower objects in a system and that, when the faster objects are embedded, the new system can really perform faster than the old one.

Organization of this paper: In the next section we briefly present our basic ideas concerning the process calculus and then define its syntax and semantics. In Section 3 we define two timed pre-bisimulations that can relate two processes according to their speeds. In Section 4 we briefly survey some related work, and in the final section we make some concluding remarks.

2 Language

The language called *TACS* is formulated as a process calculus [2, 11, 12]. It has the ability to express most features of distributed real-time object-oriented computing: communication delay, asynchronous message passing, delayed processing, and encapsulation. Its syntax and semantics are essentially similar to those of CCS [11], except for the extensions discussed below.[4]

Basic Framework

Before formally defining *TACS*, we summarize its basic ideas.

Non-blocking Message Sending

In distributed systems, communication between remotely located objects is often realized by means of one-way asynchronous message passing. However, most process calculi are essentially based on synchronous communication, and thus we need to introduce the ability to express a *non-blocking message send.*[5] We approach expressing an asynchronous message by creating a process that does not do anything except received by an input port for the message. This is similar to several existing methods [3, 10].

The Passage of Time and Delayed Processing

We assume that time is discrete and that the passage of time in every processor elapses at the same rate.[6] The passage of one time unit is represented as a transition that proceeds synchronously in all objects, written as transition $\rightsquigarrow$. Also, most distributed real-time systems have some behaviors that depend on the passage of time. We introduce an operation that explicitly suspends its execution for a specified period, written as $\langle t \rangle$. For example, $\langle t \rangle.S$ is idle for t time units and then behaves as S.

[4] In this paper, for focusing temporal aspects in distributed real-time systems, we avoid introducing the expressive capability of a distributed system where topological connections between objects can change dynamically. However, our calculus can easily model such a system by incorporating it into the port-passing mechanism developed in [12].

[5] In our framework, we assume that the order of message arrival is indeterminate.

[6] By using the method developed in [18], we can easily introduce the ability to express multiple and inaccurate clocks.

Location-dependent Communication Delay

Communication delay is defined as the difference between the time at which an object is ready to send a message and the time at which the message reaches its destination object. The length of communication delay is often dependent on the distance between the locations of the sender and receiver objects. Therefore, we introduce the concept of object (or process) location as developed in [5] and then represent communication delay as a pair consisting of the sender location and the receiver location.[7] Each object has a location name and can receive only the messages that arrive at its location. For example, we write object S at location ℓ sending message a to an object at location ℓ' as $\ell' \uparrow a.S : \ell$.

Syntax

We first define several conventions of notation.

Definition 2.1

- Let $\mathcal{M}$ be an infinite multi-set of message names, ranged over by $a,b,\ldots$.
- Let $\mathcal{L}oc$ be an infinite set of location names, ranged over by $\ell,\ell_1,\ell_2,\ldots$.
- Let $\mathcal{T}$ be the infinite set of the non-negative natural numbers.
- Let $\mathcal{D} \subseteq \mathcal{L}oc \times \mathcal{L}oc \rightarrow 2^{\mathcal{T}}$ be a set of multivalued functions, called communication delay functions, ranged over by $delay,\ldots$. □

In our framework, we describe distributed real-time objects by means of the expressions defined below. In order to clarify our exposition, we divide the expressions into two groups: expressions for describing local objects and expressions for describing interactions among remote objects.

Definition 2.2 The set $\mathcal{S}$ of local object expressions, ranged over by $S, S_1, S_2, \ldots$ is the smallest set containing the following expressions:

$S ::= \ell \uparrow a.S$	(*Asynchronous Message Send*)
$\mid \sum_{i \in I} \downarrow a_i.S_i$	(*Selective Message Receive*)
$\mid \langle t \rangle . S$	(*Delayed Processing*)
$\mid S \mid S$	(*Parallel Execution*)
$\mid S \setminus N$	(*Message Encapsulation*)
$\mid A \stackrel{\text{def}}{=} S$	(*Recursive Definition*)

The set $\mathcal{P}$ of remote object expressions, ranged over by $P, P_1, P_2, \ldots$ is the smallest set containing the following expressions:

$P ::= S : \ell$	(*Located Object*)
$\mid P \mid P$	(*Parallel Execution*)
$\mid P \setminus N$	(*Message Encapsulation*)

[7] The concept is used in this paper only for expressing communication dependent on locations; we do not intend to investigate the concept itself.

where N is a subset of $\mathcal{M}$, I is a finite index set $\{1, 2, \ldots, n\}$, t is an element of $\mathcal{T}$, and A is a constant object expression. We assume that in $A \stackrel{\text{def}}{=} S$ if S contains A, A occurs only within subexpressions in $\mathcal{S}$ of the form $\sum_{i \in I} \downarrow a_i.S_i'$ or $\langle t \rangle . S'$ $(t > 0)$ in S. We write $\mathbf{0}$ for an empty summation (i.e., $\sum_{i \in \emptyset} \downarrow a_i.S_i$). We also assume that a_i is not an empty name in $\sum_{i \in I} \downarrow a_i.S_i'$ (where $I \neq \emptyset$). We often use the more readable notation $\downarrow a_1.S_1 + \cdots + \downarrow a_n.S_n$ instead of $\sum_{i \in \{1,\ldots,n\}} \downarrow a_i.S_i$ and write $A{:}\ell \stackrel{\text{def}}{=} S{:}\ell$ if $A \stackrel{\text{def}}{=} S$. □

The intuitive meaning of constructors in $\mathcal{S}$ (and $\mathcal{P}$) is as follows:

- $\mathbf{0}$ represents a terminated or deadlocked object.
- $\ell' \uparrow a.S$: sends message a to an object at location ℓ', and continues to execute S without blocking.
- $\sum_{i \in I} \downarrow a_i.S_i$ behaves as S_i if it receives message a_i.
- $\langle t \rangle.S$ is idle for t time units and then behaves like S.
- $S_1 \mid S_2$ allows S_1 and S_2 to execute in parallel.
- $S \setminus N$ encapsulates all messages in set N.
- $A \stackrel{\text{def}}{=} S$ says that A is defined as S. S is allowed to include A.
- $S{:}\ell$ is an object located at ℓ.

We define a function for extracting the name of an object location from P expressions.

Definition 2.3 The function $|\cdot|_{Loc} : \mathcal{P} \to 2^{\mathcal{L}oc}$, which presents the location names of objects, is defined as follows:

$$|S{:}\ell|_{Loc} = \{\ell\}, \quad |P_1|P_2|_{Loc} = |P_2|_{Loc} \cup |P_2|_{Loc}, \quad |P \setminus N|_{Loc} = |P|_{Loc} \ \square$$

Semantics

The operational semantics of *TACS* is given by two kinds of state transition relations: $\rightarrow \subseteq \mathcal{P} \times \mathcal{P}$ (called *behavioral transition*) and $\rightsquigarrow \subseteq \mathcal{P} \times \mathcal{P}$ (called *temporal transition*). Throughout this paper we will use a structural equivalence relation $(\equiv)$ over expressions. This is the method followed by Milner in [13] to deal with the π-calculus. The use of the structural equivalence relation allows us to concentrate on the investigation of inequalities between objects as shown in the following section.

Definition 2.4 $\equiv$ is the least syntactic equivalence defined by the following equations:

$$P_1 \mid P_2 \equiv P_2 \mid P_1 \qquad P_1 \mid (P_2 \mid P_3) \equiv (P_1 \mid P_2) \mid P_3 \qquad P \mid \mathbf{0}{:}\ell \equiv P$$
$$(S_1 \mid S_2) : \ell \equiv S_1 : \ell \mid S_2 : \ell \qquad \mathbf{0}{:}\ell \setminus N \equiv \mathbf{0}{:}\ell \qquad S \setminus N{:}\ell \equiv S : \ell \setminus N$$
$$P \setminus N_1 \setminus N_2 \equiv P \setminus N_2 \setminus N_1 \qquad (P \mid \ell' \uparrow a.\mathbf{0}{:}\ell) \setminus N \equiv P \setminus N \mid \ell' \uparrow a.\mathbf{0}{:}\ell \text{ where } a \notin N$$
$$\langle 0 \rangle.S{:}\ell \equiv S{:}\ell$$

We now present the operational semantics of our language.

Definition 2.5 *Behavioral transition* $\rightarrow \subseteq \mathcal{P} \times \mathcal{P}$ (written $P \rightarrow P'$) is the least binary relation given by the following axioms and rules.

$$\ell' \uparrow a.S{:}\ell \rightarrow S{:}\ell \mid \langle t \rangle . \epsilon \uparrow a.\mathbf{0}{:}\ell' \quad (t \in \mathit{delay}(\ell, \ell') \text{ and } \ell' \text{ is not } \epsilon)$$

$$\textstyle\sum_{i \in I} \downarrow a_i.S_i{:}\ell \mid \epsilon \uparrow a_i.\mathbf{0}{:}\ell \rightarrow S_i{:}\ell \mid \mathbf{0}{:}\ell$$

$$\frac{P_1 \rightarrow P_1'}{P_1 \mid P_2 \rightarrow P_1' \mid P_2} \qquad \frac{P \rightarrow P'}{P \setminus N \rightarrow P' \setminus N}$$

$$\frac{S{:}\ell \rightarrow S'{:}\ell}{A{:}\ell \rightarrow S'{:}\ell}\ (A \stackrel{\text{def}}{=} S) \qquad \frac{P_1 \equiv P_1', \quad P_1 \rightarrow P_2, \quad P_2 \equiv P_2'}{P_1' \rightarrow P_2'}$$

where $\mathit{delay} \in \mathcal{D}$. ϵ is an empty location name. We often write $(\equiv)^* \rightarrow (\equiv)^*$ as $\rightarrow$ when there is not ambiguity. □

Definition 2.6 *Temporal transition* $\rightsquigarrow \subseteq \mathcal{P} \times \mathcal{P}$ (written $P \rightsquigarrow P'$) is the least binary relation defined by the following axioms and rules.

$$\langle t \rangle . S{:}\ell \rightsquigarrow \langle t-1 \rangle . S{:}\ell \quad (t > 0) \qquad \epsilon \uparrow a.\mathbf{0}{:}\ell \rightsquigarrow \epsilon \uparrow a.\mathbf{0}{:}\ell$$

$$\textstyle\sum_{i \in I} \downarrow a_i . S_i{:}\ell \rightsquigarrow \sum_{i \in I} \downarrow a_i . S_i{:}\ell$$

$$\frac{P_1 \rightsquigarrow P_1', \quad P_2 \rightsquigarrow P_2', \quad P_1 \mid P_2 \not\rightarrow}{P_1 \mid P_2 \rightsquigarrow P_1' \mid P_2'} \qquad \frac{P \rightsquigarrow P'}{P \setminus N \rightsquigarrow P' \setminus N}$$

$$\frac{S{:}\ell \rightsquigarrow S'{:}\ell}{A{:}\ell \rightsquigarrow S'{:}\ell}\ (A \stackrel{\text{def}}{=} S) \qquad \frac{P_1 \equiv P_1', \quad P_1 \rightsquigarrow P_2, \quad P_2 \equiv P_2'}{P_1' \rightsquigarrow P_2'}$$

where we often write $(\equiv)^* \rightsquigarrow (\equiv)^*$ as $\rightsquigarrow$ when there is not ambiguity. □

Remarks on the above transition rules:

- The first axiom of Definition 2.5 shows that a non-blocking message send, $\ell' \uparrow a.S{:}\ell$, is translated into two parallel processes: $S{:}\ell$ and $\langle t \rangle . \epsilon \uparrow a.\mathbf{0}{:}\ell'$. The former corresponds to the subsequent computation. Note that it can continue to execute without any blocking. The latter corresponds to the asynchronous message. Before it can be received by an object at location ℓ', it is suspended for communication delay time from ℓ to ℓ', written as $\mathit{delay}(\ell, \ell')$. If communication delay is indeterminate, the suspension time is given as a time value of all the possible communication delays non-deterministically.
- The second axiom of Definition 2.5 defines the semantics of message reception. A message can be consumed only by a receiver having a corresponding input port at the same location as the message's destination location.

- Our semantics forces message sending and receiving to be performed as soon as they are executable, without unnecessary delay. This preemptiveness allows us to estimate the necessary execution time of interactions among distributed objects exactly and express several important timed operations, including timeout handling.[8]

In the following section we introduce two order relations with the notion of remote observation, using conceptual observers residing at specified locations. The observers make comparisons between two remote objects (or object groups) by sending arbitrary messages to the objects and receiving messages from them. The observers can know only the length of the passage of time and the messages which arrive at their own locations. They cannot observe any encapsulated computation nor any message passing at locations other than their own ones. The formal representation of the notion is given as labels for behavioral transitions like the weak transitions presented in [11].[9] We define the labeled transitions as follows:

Definition 2.7 Let a range over $\mathcal{M}$, t range over $\mathcal{T}$, and ℓ, ℓ' range over $\mathcal{L}$. The labeled translations are denoted as follows:

- $P \xrightarrow{\langle t\rangle\uparrow a}_{\ell} P'$ is defined as $P \to^* \langle t\rangle\epsilon\uparrow a.\mathbf{0}{:}\ell \mid P'$
- $P \xrightarrow{\langle t\rangle\ell'\downarrow a}_{\ell} P'$ is defined as $\langle t\rangle\ell'\uparrow a.\mathbf{0}{:}\ell \mid P \to^* P'$
- $P \rightsquigarrow^t P'$ is defined as $P \underbrace{\to^* \rightsquigarrow \to^* \cdots \to^* \rightsquigarrow \to^*}_{t \text{ times}} P'$

where $P \to^* P'$ is given as $P \to \cdots \to P'$. We often abbreviate $P \xrightarrow{\langle 0\rangle\uparrow a}_{\ell} P'$ to $P \xrightarrow{\uparrow a}_{\ell} P'$. □

The above labeled transitions have the following intuitive meaning: $P \xrightarrow{\langle t\rangle\uparrow a}_{\ell} P'$ means that P behaves as P' and an observer located at ℓ receives message a from P after t time units; $P \xrightarrow{\langle t\rangle\ell'\downarrow a}_{\ell} P'$ means that P behaves as P' and an observer located at ℓ sends message a to an object at location ℓ' after t time units. Object P may receive the message if it is located at ℓ'; $P \rightsquigarrow^t P'$ means that P becomes P' after t time units and arbitrary times of internal computations.

The following example illustrates how to describe distributed real-time objects in *TACS*.

Example 2.8 We describe a simple communication protocol for a communication network with transmission delay and failure. The protocol consists of a sender object at location ℓ_S and a receiver object at location ℓ_R. The sender sends a message to the receiver ($\ell_R\uparrow$ *send*) and waits for an acknowledgment

[8] We leave details of a non-preemptive version of this calculus to another paper [20].

[9] We can formalize the relations without using labels for transitions. However, the use of labeled transitions allows us to present and prove some properties of the relations more simply.

($\downarrow ack$). If it does not receive the acknowledgment within eight time units, it retransmits the message. The receiver receives the message ($\downarrow send$) and then returns an acknowledgment ($\ell_S \uparrow ack$). These objects are described as follows:

$$\begin{aligned} Sender : \ell_S &\stackrel{\text{def}}{=} (\ell_R \uparrow send \,.\, (\downarrow ack.\mathbf{0} + \downarrow timeout \,.\, Sender) \mid \\ &\qquad \langle 8 \rangle \,.\, \ell_S \uparrow timeout \,.\, \mathbf{0}) \setminus \{timeout\} : \ell_S \\ Receiver : \ell_R &\stackrel{\text{def}}{=} \downarrow send \,.\, \ell_S \uparrow ack \,.\, \mathbf{0} : \ell_R \end{aligned}$$

We assume that communication from ℓ_S to ℓ_R takes 3 ± 1 time units and may occasionally fail, and that communication from ℓ_R to ℓ_S takes 2 ± 1 time units and may occasionally fail.

$$\begin{aligned} delay(\ell_S, \ell_R) &= \{2, 3, 4\} \cup \{\infty\} \\ delay(\ell_R, \ell_S) &= \{1, 2, 3\} \cup \{\infty\} \\ delay(\ell_S, \ell_S) &= \{0\} \end{aligned}$$

where ∞ corresponds to a communication failure. By expanding ($Sender : \ell_S \mid Receiver : \ell_R$) $\setminus \{send, ack\}$ in the above transition, we can strictly analyze both the behavioral properties and the temporal properties of the entire system, including the influence of non-determinacy on communication delay.

Due to lack of space, we demonstrate an interaction between the two objects below, when we assume that $delay(\ell_S, \ell_R)$ is three time units and $delay(\ell_R, \ell_S)$ is two time units.

$$\begin{aligned} &(Sender : \ell_S \mid Receiver : \ell_R) \setminus \{send, ack\} \\ &\quad \rightarrow (\langle 3 \rangle \,.\, \epsilon \uparrow send \,.\, \mathbf{0} : \ell_R \mid ((\downarrow ack \,.\, \mathbf{0} + \downarrow timeout \,.\, Sender) : \ell_S \mid \\ &\qquad \langle 8 \rangle \,.\, \ell_S \uparrow timeout \,.\, \mathbf{0} : \ell_S) \setminus \{timeout\} \mid \downarrow send \,.\, \ell_S \uparrow ack \,.\, \mathbf{0} : \ell_R) \setminus \{send, ack\} \\ &\quad \rightsquigarrow^3 (\epsilon \uparrow send \,.\, \mathbf{0} : \ell_R \mid ((\downarrow ack \,.\, \mathbf{0} + \downarrow timeout \,.\, Sender) : \ell_S \mid \\ &\qquad \langle 5 \rangle \,.\, \ell_S \uparrow timeout \,.\, \mathbf{0} : \ell_S) \setminus \{timeout\} \mid \downarrow send \,.\, \ell_S \uparrow ack \,.\, \mathbf{0} : \ell_R) \setminus \{send, ack\} \\ &\quad \rightarrow (((\downarrow ack \,.\, \mathbf{0} + \downarrow timeout \,.\, Sender) : \ell_S \mid \\ &\qquad \langle 5 \rangle \,.\, \ell_S \uparrow timeout \,.\, \mathbf{0} : \ell_S) \setminus \{timeout\} \mid \ell_S \uparrow ack \,.\, \mathbf{0} : \ell_R) \setminus \{send, ack\} \\ &\quad \rightarrow (((\downarrow ack \,.\, \mathbf{0} + \downarrow timeout \,.\, Sender) : \ell_S \mid \\ &\qquad \langle 5 \rangle \,.\, \ell_S \uparrow timeout \,.\, \mathbf{0} : \ell_S) \setminus \{timeout\} \mid \langle 2 \rangle \,.\, \epsilon \uparrow ack \,.\, \mathbf{0} : \ell_S \mid \mathbf{0} : \ell_R) \setminus \{send, ack\} \\ &\quad \rightsquigarrow^2 (((\downarrow ack \,.\, \mathbf{0} + \downarrow timeout \,.\, Sender) : \ell_S \mid \\ &\qquad \langle 3 \rangle \,.\, \ell_S \uparrow timeout \,.\, \mathbf{0} : \ell_S) \setminus \{timeout\} \mid \epsilon \uparrow ack \,.\, \mathbf{0} : \ell_S) \setminus \{send, ack\} \\ &\quad \rightarrow (\mathbf{0} : \ell_S \mid \mathbf{0} : \ell_R) \qquad \textit{(successful)} \end{aligned}$$

3 Verification for Distributed Real-Time Objects

This section presents two algebraic order relations on distributed real-time objects with respect to speed. In the last few years, many timed equivalence relations for synchronously communicating processes (or objects) have already been explored in timed extended process calculi (for example see [14, 15, 17]). These

relations equate two processes only when their temporal and behavioral properties completely match. The temporal strictness of these relations is appropriate in verifying synchronously communicating real-time objects. This is because in synchronous communication settings every sender object must synchronize with its receiver. Therefore, even if a sender object can send a message earlier than its temporal specification, the object may not send it then if its receiver object is not fast enough.

On the other hand, in asynchronous communication settings, sender objects do not have to synchronize with their receiver objects and thus may send messages as soon as they are able to. Therefore, in these settings real-time objects do not need to completely match their own temporal specification, and need only to deliver messages to their receiver objects at times earlier than those given in their specifications. This reveals that in the verification of asynchronously communicating real-time objects, "speed-sensitive" order relations are more suitable and practical than the above timed equivalences. In this section, we investigate algebraic order relations that decide whether two real-time objects are behaviorally equivalent and whether one of them can perform *faster* than the other.

Relating Objects with Respect to Speed

Before defining the relations, we first illustrate the basic idea behind them. Suppose two simple objects: $A_1 \stackrel{\text{def}}{=} \langle 1 \rangle . \ell \uparrow a.S : \ell_A$ and $A_2 \stackrel{\text{def}}{=} \langle 3 \rangle . \ell \uparrow a.S : \ell_A$, where ℓ is a conceptual observer's location. A_1 can send message a to the observer after one time unit, and A_2 can send the same message after three time units. That is, A_1 can send the message sooner than A_2. Therefore, we would consider object A_1 to be *faster* than object A_2. Now we define such a speed-sensitive order relation based on the notion of the observation bisimulation [11].

Definition 3.1 A binary relation $\mathcal{R} \subseteq (\mathcal{P} \times \mathcal{P}) \times \mathcal{T} \times 2^{\mathcal{L}oc}$ is a *t-speed prebisimulation* on L if $(P_1, P_2) \in \mathcal{R}_t^L$ ($t \in \mathcal{T}$ and $L \subseteq \mathcal{L}oc$) implies, for all $a, b \in \mathcal{M} \cup \{\epsilon\}$, $\ell, \ell' \in L$, and $d \in \mathcal{T}$;

(i) $\forall \ell_1, \forall m_1, \forall P_1' : P_1 \stackrel{\langle d \rangle \ell_1 \downarrow a}{\longrightarrow\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_1} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\rightarrow}_{\ell'} P_1'$ *then*
$\exists \ell_2, \exists m_2, \exists P_2' : P_2 \stackrel{\langle d \rangle \ell_2 \downarrow a}{\longrightarrow\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_2} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\rightarrow}_{\ell'} P_2'$ *and* $(P_1', P_2') \in \mathcal{R}_{t-m_1+m_2}^L$

(ii) $\forall \ell_2, \forall m_2, \forall P_2' : P_2 \stackrel{\langle d \rangle \ell_2 \downarrow a}{\longrightarrow\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_2} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\rightarrow}_{\ell'} P_2'$ *then*
$\exists \ell_1, \exists m_1, \exists P_1' : P_1 \stackrel{\langle d \rangle \ell_1 \downarrow a}{\longrightarrow\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_1} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\rightarrow}_{\ell'} P_1'$ *and* $(P_1', P_2') \in \mathcal{R}_{t-m_1+m_2}^L$

where $\ell_1 \in |P_1|_{Loc}$, $\ell_2 \in |P_2|_{Loc}$. We let $P_1 \preceq_t^L P_2$ if there exists a t-speed prebisimulation on L such that $(P_1, P_2) \in \mathcal{R}_t^L$. We call $\preceq_t^L$ *t-speed order* on L. We shall often abbreviate $\preceq_0^L$ as $\preceq^L$. □

In the above definition, $\mathcal{R}_t^L$ is a family of relations indexed by a non-negative time value t. Intuitively, t is the relative difference between the time of P_1 and that of

P_2; that is, it means that P_1 precedes P_2 by t time units.[10] $\preceq_t^L$ starts with a pre-bisimulation indexed by t (i.e., $\mathcal{R}_t^L$) and can change t as the bisimulation proceeds only if $t \geq 0$. L corresponds to the set of the locations of conceptual observers. The bisimulation makes two objects interact with the observers (i.e., arbitrary objects) at L and relates them according to the temporal and behavioral results of the interactions. P_1 (or P_2) may be an object or a group of objects at the same or different locations.

We here state the informal meaning of $P_1 \preceq_t^L P_2$. We first assume that conceptual observers are at locations in L and that P_1 precedes P_2 by t time units. An observer at location ℓ ($\ell \in L$) sends a message to P_1 after d time units (written as $P_1 \stackrel{\langle d \rangle \ell_1 \downarrow a}{\longrightarrow\!\!\!\!\!\rightarrow} \ell$ in (i)). It also sends the same message to P_2 after d time units (written as $P_2 \stackrel{\langle d \rangle \ell_2 \downarrow a}{\longrightarrow\!\!\!\!\!\rightarrow} \ell$ in (ii)). An observer at location ℓ' ($\ell' \in L$) then receives return messages from P_1 and P_2 after m_1 time units and m_2 time units, respectively (written as $\rightsquigarrow^{m_1} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell'} P_1'$ and $\rightsquigarrow^{m_2} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell'} P_2'$). If the arrival time of the return message from P_1 is earlier than that from P_2,[11] and if P_1' and P_2' can be successfully observed in $(P_1', P_2') \in \mathcal{R}_{t-m_1+m_2}^L$ in the same way, the observers judge that P_1 and P_2 are behaviorally equivalent and that P_1 can perform its behaviors *faster* than P_2.

We show several basic properties of the order relation below.

Proposition 3.2 Let $P, P_1, P_2, P_3 \in \mathcal{P}$ $t, t_1, t_2 \in \mathcal{T}$, and $L \subseteq \mathcal{L}oc$ then,

(1) $P \preceq_t^L P$
(2) *If* $P_1 \preceq_{t_1}^L P_2$ *and* $P_2 \preceq_{t_2}^L P_3$ *then* $P_1 \preceq_{t_1+t_2}^L P_3$

where for all $\ell \in L$ and $\dot{\ell} \in |P|_{Loc}$, $delay(\ell, \dot{\ell})$ and $delay(\dot{\ell}, \ell')$ are constant. □

From these results, we see that $P \preceq^L P$ and that if $P_1 \preceq^L P_2$ and $P_2 \preceq^L P_3$ then $P_1 \preceq^L P_3$. Hence, $\preceq^L$ is a preorder relation.

Proposition 3.3 Let $P_1, P_2 \in \mathcal{P}$, $L \subseteq \mathcal{L}oc$, and $t, t_1, t_2 \in \mathcal{T}$ then,

(1) *If* $P_1 \preceq_t^L P_2$ *and* $t \leq t'$ *then* $P_1 \preceq_{t'}^L P_2$
(2) *If* $P_1 \preceq_t^L P_2$ *and* $L' \subseteq L$ *then* $P_1 \preceq_t^{L'} P_2$ □

This proposition is significant in revealing the meanings of the indexes of $\preceq_t^L$. (1) means that P_1 performs at most t time units faster than P_2 and thus P_1 can still perform at most t' time units faster than P_2 if $t \leq t'$. (2) means that L in $\preceq_t^L$ corresponds to all the locations at which the observers can send and receive messages, and two objects ordered by an observer can be still ordered by another observer having a more limited scope $L' \subseteq L$.

[10] This means that the performance of P_1 is at most t time units faster than that of P_2.

[11] Note that P_2 already precedes P_1 by t time units. Thus, the relative difference between the arrival time of the message from P_2 and that from P_1 is $t - m_1 + m_2$ time units.

Proposition 3.4 Let $S_1:\ell, S_2:\ell, P_1, P_2 \in \mathcal{P}$, $L \subseteq \mathcal{L}oc$, and $t, d \in \mathcal{T}$ then,

(1) *If* $S_1:\ell \preceq_t^L S_2:\ell$ *then* $\downarrow a.S_1:\ell \preceq_t^L \downarrow a.S_2:\ell$
(2) *If* $S_1:\ell \preceq_t^L S_2:\ell$ *then* $\ell'\uparrow a.S_1:\ell \preceq_t^L \ell'\uparrow a.S_2:\ell$
(3) *If* $P_1 \preceq_t^L P_2$ *then* $P_1 \setminus N \preceq_t^L P_2 \setminus N$ □

When for all $\ell' \in L$, $t, d \in \mathcal{T}$, $delay(\ell, \ell') = delay(\ell', \ell) = 0$, from $S_1:\ell \preceq_t^L S_2:\ell$, $\langle d\rangle.S_1:\ell \preceq_t^L \langle d\rangle.S_2:\ell$ is derived.

Remark We defined a speed order relation where the index t may not be zero in order to investigate its basic properties. However, we will usually use $\preceq_0^L$ in verifying systems.

Example 3.5 We present some examples to demonstrate how $\preceq^L$ works. To simplify, we assume that communication delay can be ignored.

(1) $\langle 1\rangle.\ell\uparrow a.\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell' \preceq^L \langle 2\rangle.\ell\uparrow a.\langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell'$ *where* $\ell \in L$

We verify this relation. We assume the following relation

$$\mathcal{R}_0^L = (\langle 1\rangle.\ell\uparrow a.\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell', \langle 2\rangle.\ell\uparrow a.\langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell').$$

We first prove that the relation satisfies (i) in Definition 3.1. If $\langle 1\rangle.\ell\uparrow a.\langle 3\rangle\ell\uparrow b.\mathbf{0}:\ell' \rightsquigarrow^1 \xrightarrow{\uparrow a}_\ell \langle 3\rangle\ell\uparrow b.\mathbf{0}:\ell'$ then

$$\langle 2\rangle.\ell\uparrow a.\langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell' \rightsquigarrow^2 \xrightarrow{\uparrow a}_\ell \langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell' \text{ and } (\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell', \langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell') \in \mathcal{R}_{0-1+2}^L.$$

Moreover, $\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell' \rightsquigarrow^3 \xrightarrow{\uparrow b}_\ell \mathbf{0}:\ell'$ then

$$\langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell' \rightsquigarrow^2 \xrightarrow{\uparrow b}_\ell \mathbf{0}:\ell' \text{ and } (\mathbf{0}:\ell', \mathbf{0}:\ell') \in \mathcal{R}_{1-3+2}^L.$$

We can verify that $\mathcal{R}_0^L$ satisfies (ii) in Definition 3.1 in the same way.

(2) $\langle 1\rangle.\downarrow a.\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell' \not\preceq^L \langle 2\rangle.\downarrow a.\langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell'$ *where* $\ell \in L$

It is enough to consider a counterexample. Suppose $\langle 1\rangle.\downarrow a.\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell' \xrightarrow{\langle 3\rangle\ell'\downarrow a}_\ell \rightsquigarrow^3 \langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell'$, while $\langle 2\rangle.\downarrow a.\langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell' \xrightarrow{\langle 3\rangle\ell'\downarrow a}_\ell \rightsquigarrow^3 \langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell'$. Clearly, $(\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell', \langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell')$ is not a speed pre-bisimulation.

(3) Next, assume these objects are allocated on different processors. For all $\ell \in L$, the communication delay from ℓ_1 to ℓ is three time units and that from ℓ_2 to ℓ is one time units: $delay(\ell_1, \ell) = \{3\}$ and $delay(\ell_2, \ell) = \{1\}$. we have:

$$\langle 2\rangle.\ell\uparrow a.\langle 2\rangle.\ell\uparrow b.\mathbf{0}:\ell_2 \preceq^L \langle 1\rangle.\ell\uparrow a.\langle 3\rangle.\ell\uparrow b.\mathbf{0}:\ell_1$$

Cooperationability for Distributed Real-Time Objects

It is very convenient to develop a pre-congruence with respect to speeds in order to guarantee substitutability between two ordered objects. However, there is a problem in defining such a pre-congruence with temporal inequality. Suppose

four objects: $A_1 : \ell_A \stackrel{\text{def}}{=} \langle 1 \rangle.\ell_B \uparrow a.\mathbf{0} : \ell_A$, $A_2 : \ell_A \stackrel{\text{def}}{=} \langle 4 \rangle.\ell_B \uparrow a.\mathbf{0} : \ell_A$, $B_1 : \ell_B \stackrel{\text{def}}{=} ((\downarrow a.B' + \downarrow b.B'') \mid \langle 2 \rangle.\ell_B \uparrow b.\mathbf{0}) \setminus \{b\} : \ell_B$, and $B_2 : \ell_B \stackrel{\text{def}}{=} \langle 1 \rangle.((\downarrow a.B' + \downarrow b.B'') \mid \langle 2 \rangle.\ell_B \uparrow b.\mathbf{0}) \setminus \{b\} : \ell_B$, where $delay(\ell_A, \ell_B) = 0$. Clearly $A_1 \preceq^L A_2$ and $B_1 \preceq^L B_2$ hold, but $A_1 | B_1 \preceq^L A_2 | B_2$ does not hold. This fact reveals that a slower object cannot always be replaced by a faster object in a parallel composition with other objects. This anomaly is traced to contexts that restrict the capability to execute a particular computation due to the passage of time, for example *timeout* handling in B_1 and B_2. In order to define a rational pre-congruence with respect to speed, we here define another order relation which is a little more strict than the $\preceq_t^L$ relation, and a restricted expression of $\mathcal{P}$.

Definition 3.6 A binary relation $\mathcal{R} \subseteq (\mathcal{P} \times \mathcal{P}) \times \mathcal{T} \times 2^{\mathcal{L}oc}$ is a *t-timed pre-bisimulation* on L if $(P_1, P_2) \in \mathcal{R}_L^t$ ($t \in \mathcal{T}$ and $L \subseteq \mathcal{L}oc$) implies, for all $a, b \in \mathcal{M}$, $\ell, \ell', \in L$, $\dot{\ell} \in |P_1|_{Loc} \cup |P_2|_{Loc}$, and $d_1, d_2 \in \mathcal{T}$ such that $d_1 \leq d_2 + t$;

(i) $\forall m_1, \forall P_1' : P_1 \stackrel{\langle d_1 \rangle \dot{\ell} \downarrow a}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_1} P_1'$ *then*
$\forall m_2, \exists P_2' : P_2 \stackrel{\langle d_2 \rangle \dot{\ell} \downarrow a}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_2} P_2'$ *and* $(P_1', P_2') \in \mathcal{R}^L_{t-m_1+m_2}$

(ii) $\forall m_2, \forall P_2' : P_2 \stackrel{\langle d_2 \rangle \dot{\ell} \downarrow a}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_2} P_2'$ *then*
$\forall m_1, \exists P_1' : P_1 \stackrel{\langle d_1 \rangle \dot{\ell} \downarrow a}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell} \rightsquigarrow^{m_1} P_1'$ *and* $(P_1', P_2') \in \mathcal{R}^L_{t-m_1+m_2}$

(iii) $\forall m_1, \forall P_1' : P_1 \rightsquigarrow^{m_1} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell'} P_1'$ *then*
$\exists m_2, \exists P_2' : P_2 \rightsquigarrow^{m_2} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell'} P_2'$ *and* $(P_1', P_2') \in \mathcal{R}^L_{t-m_1+m_2}$

(iv) $\forall m_2, \forall P_2' : P_2 \rightsquigarrow^{m_2} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell'} P_2'$ *then*
$\exists m_1, \exists P_1' : P_1 \rightsquigarrow^{m_1} \stackrel{\uparrow b}{\longrightarrow\!\!\!\!\!\rightarrow}_{\ell'} P_1'$ *and* $(P_1', P_2') \in \mathcal{R}^L_{t-m_1+m_2}$

For $P_1, P_2 \in \mathcal{P}$, we let $P_1 \trianglelefteq_t^L P_2$ if there exists a t-timed pre-bisimulation on L such that $(P_1, P_2) \in \mathcal{R}_t^L$. We call $\trianglelefteq_t^L$ *t-timed order* on L. We shall often abbreviate $\trianglelefteq_0^L$ as $\trianglelefteq^L$. □

This relation is basically similar to $\preceq_t^L$ except that the observers of $\trianglelefteq_t^L$ are slightly stricter. That is, whereas the observer of $\preceq_t^L$ sends a message to the concerned objects after the same number of time units, the observer of $\trianglelefteq_t^L$ sends a message to the slower object after arbitrarily more time units than the number of time units after which it sends the message to the faster object. To allow easier discussion hereafter, we define the following restricted expression.

Definition 3.7 Let $P \in \mathcal{P}$ and $L \subseteq \mathcal{L}oc$, if $P \trianglelefteq_0^L P$, we call P a *non-timeout* expression on L. □

From Definition 3.6, we directly know that for all $P_1, P_2, P_3 \in \mathcal{P}$, If $P_1 \trianglelefteq_{t_1}^L P_2$ and $P_2 \trianglelefteq_{t_2}^L P_3$ then $P_1 \trianglelefteq_{t_1+t_2}^L P_3$. Hence, $\trianglelefteq_0^L$ is a preorder relation on non-timeout expressions.

Proposition 3.8 Let $P_1, P_2 \in \mathcal{P}$, $L \subseteq \mathcal{L}oc$, and $t \in \mathcal{T}$ then,

(1) *If* $P_1 \trianglelefteq_t^L P_2$ *then* $P_1 \preceq_t^L P_2$
(2) *If* $P_1 \trianglelefteq_t^L P_2$ *and* $L' \subseteq L$ *then* $P_1 \trianglelefteq_t^{L'} P_2$ □

The first above result shows that $\preceq_t^L$ at least includes $\trianglelefteq_t^L$.

Proposition 3.9 Let $P_1, P_2 \in \mathcal{P}$, $delay_1, delay_2 \in \mathcal{D}$ such that for all $\ell \in L$, $\ell_2 \in |P_2|_{Loc}$: $delay_1(\ell, \ell_2) \leq delay_2(\ell, \ell_2)$ and $delay_1(\ell_2, \ell) \leq delay_2(\ell_2, \ell)$,

If $P_1 \trianglelefteq_t^L P_2$ *assuming* $delay_1$ *then* $P_1 \trianglelefteq_t^L P_2$ *assuming* $delay_2$ □

This proposition shows that a slower object is still slower even from an observer residing at a further location. However, we cannot assume the similar proposition about the first expression. That is, for all $delay_1, delay_2 \in \mathcal{D}$ such that $\forall \ell \in L, \ell_1 \in |P_1|_{Loc}$: $delay_1(\ell, \ell_1) \geq delay_2(\ell, \ell_1)$ and $delay_1(\ell_1, \ell) \geq delay_2(\ell_1, \ell)$ then, from $P_1 \trianglelefteq_t^L P_2$ assuming $delay_1$, $P_1 \trianglelefteq_t^L P_2$ assuming $delay_2$ is not usually derived. This is because the observer of $\trianglelefteq_t^L$ cannot notice any difference between its ordered objects before the observer receives their first messages.

Proposition 3.10 Let $S_1 : \ell, S_2 : \ell, P_1, P_2 \in \mathcal{P}$, $L \subseteq \mathcal{L}oc$, and $t \in \mathcal{T}$ then,

(1) *If* $S_1 : \ell \trianglelefteq_0^L S_2 : \ell$ *then* $\downarrow a.S_1 : \ell \trianglelefteq_0^L \downarrow a.S_2 : \ell$
(2) *If* $S_1 : \ell \trianglelefteq_t^L S_2 : \ell$ *then* $\ell' \uparrow a.S_1 : \ell \trianglelefteq_t^L \ell' \uparrow a.S_2 : \ell$
(3) *If* $P_1 \trianglelefteq_t^L P_2$ *then* $P_1 \setminus N \trianglelefteq_t^L P_2 \setminus N$ □

When for all $\ell' \in L$, $delay(\ell, \ell') = delay(\ell', \ell) = 0$, if $S_1 : \ell \trianglelefteq_t^L S_2 : \ell$ and $t_1 \leq t_2$ then $\langle t_1 \rangle.S_1 : \ell \trianglelefteq_t^L \langle t_2 \rangle.S_2 : \ell$. We next show a significant fact for proving substitutability between two behaviorally equivalent objects with different speeds.

Proposition 3.11 Let $P_1, P_2, Q_1, Q_2 \in \mathcal{P}$ be non-timeout expressions on L such that $|P_1|_{Loc}, |P_2|_{Loc}, |Q_1|_{Loc}, |Q_2|_{Loc} \subseteq L$ then, when $P_1|Q_1$ and $P_2|Q_2$ are non-timeout expressions on L,

If $P_1 \trianglelefteq_t^L P_2$ *and* $Q_1 \trianglelefteq_t^L Q_2$ *then* $P_1 \,|\, Q_1 \trianglelefteq_t^L P_2 \,|\, Q_2$ □

We directly know that if $P_1 \trianglelefteq^L P_2$ then $P_1|Q \trianglelefteq^L P_2|Q$. Intuitively, the result shows the following theoretically and practically significant facts:

- If two objects are behaviorally equivalent and one of them can perform faster than the other, the faster object can be behaviorally substituted for the slower one in a parallel composition.
- A parallel composition between the faster objects can really perform faster than one between the slower ones. That is, a system embedded with the faster objects can really perform faster than one embedded with the slower ones.

Remark The expressive power of non-timeout expressions is weaker than that of $\mathcal{P}$ because any expressions which contain the anomalous contexts mentioned above are no longer definable; for example, $((\downarrow a.A_1 + \downarrow b.A_2) \mid \langle 2 \rangle.\ell\uparrow b.\mathbf{0}) \setminus \{b\} : \ell$ and $(\langle 2 \rangle.\downarrow a.\mathbf{0} \mid \langle 4 \rangle.\downarrow a.\mathbf{0}) : \ell$. However, we insist that this is not an unreasonable restriction because we never lose the expressive capability for time-dependent operations which make some other event executable due to the passage of time. This restriction never affects any required expressiveness of the language in describing real-time systems which contain no timeout handling, including hard real-time systems.[12]

Example of Verification

For the remainder of this section we will present an example of the verification of distributed real-time objects to demonstrate how the order relations work.

Example 3.12 We consider two printing service systems in a distributed system. The first system consists of two remotely located objects: a printer object ($Printer_1$) at location ℓ_P and a console object ($Console_1$) at location ℓ_C. We denote the location of their environment as ℓ.

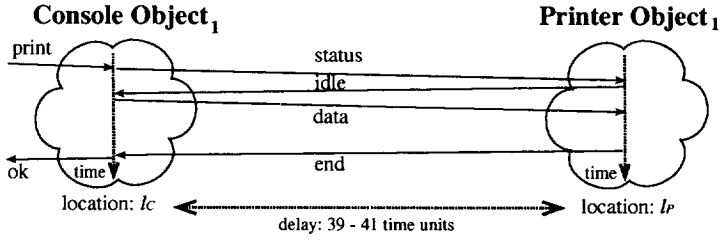

Fig. 1. The first printing service system

- Upon reception of a message ($\downarrow print$) from the environment, the console object queries the status of the printer object ($\ell_P\uparrow status$). If it receives a permission message to send data ($\downarrow idle$), it sends data to the printer ($\ell_P\uparrow data$) after an internal execution for 5 time units and waits for a completion notice of the print ($\downarrow end$). After receiving the notice, it sends a message to the environment ($\ell\uparrow ok$).

[12] On the contrary, every expression in $\mathcal{P}$ can satisfy all the propositions presented in this section, if we alter the fourth rule of Definition 2.6 into "$P_1 \rightsquigarrow P_1'$ and $P_2 \rightsquigarrow P_2'$ imply $P_1|P_2 \rightsquigarrow P_1'|P_2'$". However, this alternation allows an executable communication to be suspended for arbitrary periods of time. We leave further details of this alternative semantics to another paper [20].

- The printer object waits for a query message ($\downarrow status$) and then returns its status ($\ell_C \uparrow idle$) after 5 time units and waits for data transmission ($\downarrow data$). It returns a print completion notice ($\ell_C \uparrow end$) after an internal execution of 60 time units.

The two objects are described as follows:

$$Console_1 : \ell_C \stackrel{\text{def}}{=} \downarrow print \,.\, \ell_P \uparrow status \,.\, \downarrow idle \,.\, \langle 5 \rangle \,.\, \ell_P \uparrow data \,.\, \downarrow end \,.\, \ell \uparrow ok \,.\, \mathbf{0} : \ell_C$$
$$Printer_1 : \ell_P \stackrel{\text{def}}{=} \downarrow status \,.\, \langle 5 \rangle \,.\, \ell_C \uparrow idle \,.\, \downarrow data \,.\, \langle 60 \rangle \,.\, \ell_C \uparrow end \,.\, Printer_1 : \ell_P$$

The first system is described as a parallel composition of the objects as follows:

$$(Printer_1 : \ell_P \mid Console_1 : \ell_C) \setminus N_1 \quad \text{where } N_1 \stackrel{\text{def}}{=} \{status, idle, data, end\}$$

Next, we consider the second printing system. It consists of three remotely located objects: a printer object ($Printer_2$) at location ℓ_P, an agent object ($Agent$) at location ℓ_A, and a console object ($Console_2$) at location ℓ_C. The agent object interacts with the printer object and the console object. The printer object is identical to that in the first system except for its message destinations.

- Upon reception of a message ($\downarrow print$), the console object sends a printing request to the agent object ($\ell_A \uparrow req$) and then waits for a notice of printing start ($\downarrow started$). After receiving the notice, it sends a message to the environment ($\ell \uparrow ok$).
- The agent object receives a printing request message ($\downarrow req$). After an internal execution of 20 time units, it queries the printer about its status ($\ell_P \uparrow status$). If the agent object receives the status ($\downarrow idle$), it sends data to the printer ($\ell_P \uparrow data$) after an internal execution of 20 time units, and then sends a message to the console ($\ell_C \uparrow started$). After that, it waits for next print request ($\downarrow req$) while waiting for a print completion notice ($\downarrow end$) from the printer object.

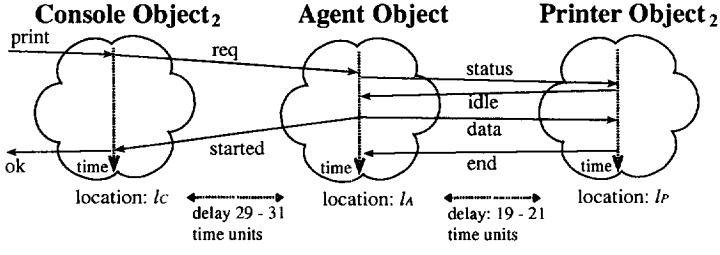

Fig. 2. The second printing service system

These objects are described as follows:

$$Console_2 : \ell_C \stackrel{\text{def}}{=} \downarrow print \,.\, \ell_A \uparrow req \,.\, \downarrow started \,.\, \ell \uparrow ok \,.\, \mathbf{0} : \ell_C$$

$$Agent : \ell_A \stackrel{\text{def}}{=} \downarrow req \,.\, \langle 20 \rangle \,.\, \ell_P \uparrow status \,.\, \downarrow idle \,.\, \langle 20 \rangle \,. \\ (\ell_P \uparrow data \,.\, \ell_C \uparrow started \,.\, \downarrow end \,.\, \mathbf{0} \mid Agent) : \ell_A$$

$$Printer_2 : \ell_P \stackrel{\text{def}}{=} \downarrow status \,.\, \langle 5 \rangle \,.\, \ell_A \uparrow idle \,.\, \downarrow data \,.\, \langle 60 \rangle \,.\, \ell_A \uparrow end \,.\, Printer_2 : \ell_P$$

The whole second system is described as a parallel composition of the three objects as follows:

$$(Printer_2 : \ell_P \mid Agent : \ell_A \mid Console_2 : \ell_C) \setminus N_2 \\ \text{where } N_2 \stackrel{\text{def}}{=} \{req, status, idle, started, data, end\}$$

We here compare the performances of these systems. We first assume that the communication delay between ℓ_C and ℓ_P is 40 ± 1 time units, that between ℓ_A and ℓ_P is 20 ± 1 time units, and that between ℓ_C and ℓ_A is 30 ± 1 time units.

$$delay(\ell_C, \ell_P) = delay(\ell_P, \ell_C) = \{39, 40, 41\} \\ delay(\ell_C, \ell_A) = delay(\ell_A, \ell_C) = \{29, 30, 31\} \\ delay(\ell_A, \ell_P) = delay(\ell_P, \ell_A) = \{19, 20, 21\}$$

We also assume that other communication channels among these locations do not exist. Using the timed order relation, the two systems are related as follows:

$$(Printer_1 : \ell_P \mid Console_1 : \ell_C) \setminus N_1 \\ \trianglelefteq^L (Printer_2 : \ell_P \mid Agent : \ell_A \mid Console_2 : \ell_C) \setminus N_2 \\ \text{where } L \subseteq \mathcal{L}\text{oc such that } \ell, \ell_A, \ell_C, \ell_P \in L$$

The above result shows that the two systems are behaviorally equivalent but that the first system can perform faster than the second one.

Also, by using the speed order relation, we can verify that the systems satisfy their specification. For example, let $Spec : \ell_C$ be the specification of the printing systems:

$$Spec : \ell_C \stackrel{\text{def}}{=} \downarrow req \,.\, \langle 300 \rangle \,.\, \ell \uparrow ok \,.\, \mathbf{0} : \ell_C$$

By using Definition 3.1, we conclude that:

$$(Printer_1 : \ell_P \mid Console_1 : \ell_C) \setminus N_1 \preceq^{\{\ell\}} Spec : \ell_C \\ (Printer_2 : \ell_P \mid Agent : \ell_A \mid Console_2 : \ell_C) \setminus N_2 \preceq^{\{\ell\}} Spec : \ell_C$$

The above inequalities show that the two systems can execute the behaviors given in the specification faster than the required execution time in the specification.

Next we will consider a reconstruction (or an improvement) of the second system. Suppose another agent object (a new implementation) described as the following $Agent' \ell_A$:

$$Agent' : \ell_A \stackrel{\text{def}}{=} \downarrow req \,.\, \langle 5 \rangle \,.\, \ell_P \uparrow status \,.\, \downarrow idle \,.\, \langle 5 \rangle \,. \\ (\ell_P \uparrow data \,.\, \ell_C \uparrow started \,.\, \downarrow end \,.\, \mathbf{0} \mid Agent') : \ell_A$$

When we apply the two agent expressions to Definition 3.6, we know the following result:

$$Agent' : \ell_A \trianglelefteq^L Agent : \ell_A$$

The above inequality tells that *Agent* and *Agent'* are behaviorally equivalent and *Agent'* can perform faster than *Agent*. In order to improve the performance of the whole second system, we replace *Agent* by *Agent'* in the system. We will need to verify that the new second system really performs faster than the old one and does not change any behavioral properties. From the inequality and Proposition 3.11, we can directly know the following desired fact:

$$\begin{aligned}(Printer_2 : \ell_P \mid Agent' : \ell_A \mid Console_2 : \ell_C) \backslash N_2 \\ \trianglelefteq^L (Printer_2 : \ell_P \mid Agent : \ell_A \mid Console_2 : \ell_C) \backslash N_2\end{aligned}$$

This demonstrates that *Agent'* can be behaviorally substituted for *Agent* in the second system and that the new second system can perform faster than the old one.[13] Moreover, by using the timed order relation we can compare the new system and the first system.

$$\begin{aligned}(Printer_2 : \ell_P \mid Agent' : \ell_A \mid Console_2 : \ell_C) \setminus N_2 \\ \trianglelefteq^L (Printer_1 : \ell_P \mid Console_1 : \ell_C) \setminus N_1\end{aligned}$$

This holds for $\preceq^L$ as well as $\trianglelefteq^L$.

4 Related Work

A number of frameworks for specifying and verifying distributed real-time systems have already been proposed based on temporal logic, automata, and process calculi. However, although there is a close relationship between delay and asynchrony in communication, general theories for modeling both delay and asynchrony seem to have been neglected in favor of ad hoc methods. On the other hand, several formal models for concurrent object-oriented computation have already been devised. Among these, process calculus [2, 6, 11, 12] is a well-studied theory that can naturally model concurrent objects as communicating processes. In this section we compare our work with some existing process calculi for modeling asynchronous communication and real-time.

Recently, several researchers have explored process calculi-related frameworks for asynchronous communication (with or without object orientation settings). Most of these frameworks introduced auxiliary mechanisms: buffering, for example see [3, 7]. However, these extensions are not always suitable for dealing with computational aspects of process calculi. On the other hand, Honda and Tokoro in [10], and Agha et al. in [1] proposed process calculi based on the notion of actor-like objects with asynchronous communication [9]. In particular, the

[13] Note that all the expressions in this example are non-timeout.

calculus in [10] which expresses asynchronous messages as newly created output processes, is very similar to ours. It also provides an equivalence theory for asynchronous communicating objects. However, its purpose is to construct a purely theoretical foundation for asynchronous communication with port passing, and it does not provide any support for the notion of time.

There have been many timed extensions of process calculi for synchronous communication, for example [8, 15, 17]. There is a notable work by Moller and Tofts in [14], in which the authors studied a preorder relation over timed processes with respect to speed based on the bisimulation concept [11] like ours. However, their order relation is seriously dependent on synchronous communication and thus cannot deal with asynchronous communication. Also their calculus, unlike ours, allows an executable communication to be suspended for arbitrary periods of time. As a result, the calculus cannot exactly analyze the execution time of systems, and their relation shows only that one process may *possibly* execute faster than another. Such a speed sensitive order relation does not seem to have been explored within process calculi in asynchronous communicating settings.

Baeten and Bergstra in [3] proposed a process calculus with the ability to express asynchronous communication channels with latency and failure, based on a timed extended calculus of ACP [2]. Their calculus introduces asynchronous messages through the creation of processes corresponding to the messages and like ours, describes communication delay as a suspension of the created process for the length of the delay time. However, it does not have any speed-sensitive order relation for asynchronously communicating processes.

5 Conclusion

In this paper we proposed a framework for specifying and verifying for distributed real-time object-oriented systems and studied its basic properties. The framework is formulated on the basis of a new timed extended process calculus. The calculus is unique among existing process calculi in expressing both delay and asynchrony in communication. It provides a powerful method for describing temporal and behavioral properties of remotely located real-time objects and their asynchronous interactions with communication delay. We also presented two speed-sensitive order relations. The relations are defined based on the bisimulation concept and can decide whether two real-time objects are behaviorally equivalent and whether one of them can perform its behaviors faster than the other. One of the relations allows us to guarantee that faster objects can be behaviorally substituted for slower ones in a system and that the system embedded with the faster objects can perform even faster than the system embedded with the slower objects. Since in asynchronous communication settings it often is necessary only to verify that real-time objects can perform faster than required by their specification, these relations offer a theoretical and practical foundation for proving the correctness and reusability of asynchronously interacting real-time objects.

Finally, we would like to point out some further issues. Our framework is not sensitive to the order of message arrival; but in several distributed systems, arriving messages are often queued in FIFO order. We therefore are very interested in developing a process calculus that takes the arrival order of messages into account. In this paper we inherently assume the existence of a global clock, but in distributed systems each processor often follows its own local clock. We have already developed a method for describing multiple local clocks in [18]. We plan to introduce the method into the framework presented in this paper. We developed some techniques to define semantics for object-oriented real-time languages with synchronous communication primitives based on a timed extended process calculus in [19]. We believe that the calculus presented here allows us to define semantics of object-oriented real-time languages with various asynchronous communication mechanisms.

Acknowledgments We are grateful to J. Sifakis (VERIMAG) for discussions on the topics treated here. We would like to thank to R. Pareschi, J.-M. Andreoli, K. Beesley (Rank Xerox Research Centre), and V. Vasconcelos (Universidade Nova de Lisboa) for giving significant comments on earlier versions of this paper, and anonymous referees for providing many constructive and valuable suggestions.
