Abstract

A graph G is (d_1, \ldots, d_l) -colorable if the vertex set of G can be partitioned into subsets V_1, \ldots, V_l such that the graph $G[V_i]$ induced by the vertices of V_i has maximum degree at most d_i for all $1 \leq i \leq l$. In this paper, we focus on complexity aspects of such colorings when l = 2, 3. More precisely, we prove that, for any fixed integers k, j, g with $(k, j) \neq (0, 0)$ and $g \geq 3$, either every planar graph with girth at least g is (k, j)-colorable or it is NP-complete to determine whether a planar graph with girth at least g is (k, j)-colorable. Also, for every fixed integer k, it is NP-complete to determine whether a planar graph that is either (0, 0, 0)-colorable or non-(k, k, 1)-colorable is (0, 0, 0)-colorable. Additionally, we exhibit non-(3, 1)-colorable planar graphs with girth 5 and non-(2, 0)-colorable planar graphs with girth 7.

1 Introduction

A graph G is (d_1, \ldots, d_k) -colorable if the vertex set of G can be partitioned into subsets V_1, \ldots, V_k such that the graph $G[V_i]$ induced by the vertices of V_i has maximum degree at most d_i for all $1 \leq i \leq k$. This notion generalizes those of proper k-coloring (when $d_1 = \cdots = d_k = 0$) and d-improper k-coloring (when $d_1 = \cdots = d_k = d \geq 1$).

Planar graphs are known to be (0, 0, 0, 0)-colorable (Appel and Haken [1, 2]) and (2, 2, 2)-colorable (Cowen, Cowen, and Woodall [13]). The (2, 2, 2)-colorability is optimal (for any integer k, there exist non-(k, k, 1)-colorable planar graphs) and holds in the choosability case (Eaton and Hull [15] or Škrekovski [23]). Improper colorings have then been considered for planar graphs with large girth or graphs with low maximum average degree. We recall that the girth of a graph G, denoted by g(G), is the length of a shortest cycle in G, and the maximum average degree of a graph G, denoted by

^{*}This work was partially supported by the ANR grant EGOS 12-JS02-002-01.

mad(G), is the maximum of the average degrees of all subgraphs of G, i.e. $mad(G) = max \{2|E(H)|/|V(H)|, H \subseteq G\}.$

(1,0)-coloring.

Glebov and Zambalaeva [20] proved that every planar graph with girth at least 16 is (1,0)-colorable. This was then strengthened by Borodin and Ivanova [3] who proved that every graph G with $mad(G) < \frac{7}{3}$ is (1,0)-colorable. This implies that every planar graph G with girth at least 14 is (1,0)-colorable. Borodin and Kostochka [7] then proved that every graph G with $mad(G) \leq \frac{12}{5}$ is (1,0)-colorable. In particular, it follows that every planar graph with girth at least 12 is (1,0)-colorable. On the other hand, they constructed graphs G with mad(G) arbitrarily close (from above) to $\frac{12}{5}$ that are not (1,0)-colorable; hence their upper bound on the maximum average degree is best possible. The last result was strengthened for triangle-free graphs: Kim, Kostochka, and Zhu [22] proved that triangle-free graphs G satisfying $11|V(G)|-9|E(G)| \ge -4$ are (1,0)-colorable. This implies that planar graphs with girth at least 11 are (1,0)-colorable. On the other hand, Esperet, Montassier, Ochem, and Pinlou [16] proved that determining whether a planar graph with girth 9 is (1,0)colorable is NP-complete. To our knowledge, the question whether all planar graphs with girth at least 10 are (1,0)-colorable is still open.

(k, 0)-coloring with $k \ge 2$.

Borodin, Ivanova, Montassier, Ochem, and Raspaud [4] proved that every graph G with $\operatorname{mad}(G) < \frac{3k+4}{k+2}$ is (k,0)-colorable. The proof in [4] extends the one in [3] but does not work for k = 1. Moreover, they exhibited a non-(k,0)-colorable planar graph with girth 6. Finally, Borodin and Kostochka [8] proved that for $k \ge 2$, every graph G with $\operatorname{mad}(G) \le \frac{3k+2}{k+1}$ is (k,0)-colorable. This result is tight in terms of maximum average degree.

(k, 1)-coloring.

Recently, Borodin, Kostochka, and Yancey [9] proved that every graph with $\operatorname{mad}(G) \leq \frac{14}{5}$ is (1, 1)-colorable, and the restriction on $\operatorname{mad}(G)$ is sharp. In [5], it is proven that every graph G with $\operatorname{mad}(G) < \frac{10k+22}{3k+9}$ is (k, 1)-colorable for $k \geq 2$.

(k, j)-coloring.

A first step was made by Havet and Sereni [21] who showed that, for every $k \ge 0$, every graph G with $\operatorname{mad}(G) < \frac{4k+4}{k+2}$ is (k,k)-colorable (in fact (k,k)-choosable). More generally, they studied k-improper l-choosability and proved that every graph G with $\operatorname{mad}(G) < l + \frac{lk}{l+k}$ ($l \ge 2, k \ge 0$) is k-improper l-choosable; this implies that such graphs are (k, \ldots, k) -colorable (where the number of partite sets is l). Borodin, Ivanova, Montassier, and Raspaud [6] gave some sufficient conditions of (k, j)-colorability depending on the density of the graphs using linear programming. Finally, Borodin and Kostochka [8]

solved the problem for a wide range of j and k: let $j \ge 0$ and $k \ge 2j + 2$; every graph G with $\operatorname{mad}(G) \le 2(2 - \frac{k+2}{(j+2)(k+1)})$ is (k, j)-colorable. This result is tight in terms of the maximum average degree and improves some results in [4, 5, 6].

Using the fact that every planar graph G with girth g(G) has mad(G) < 2g(G)/(g(G)-2), the previous results give results for planar graphs. They are summarized in Table 1, which also shows the recent results that planar graphs with girth 5 are (5,3)-colorable (Choi and Raspaud [12]) and (10,1)-colorable (Choi, Choi, Jeong, and Suh [11]).

| girth | (k,0) | (k,1) | (k,2) | (k,3) | (k, 4) |
|-------|--------------|-------------|------------|------------|------------|
| 3,4 | × | × | × | × | × |
| 5 | × | (10,1) [11] | (6,2) [8] | (5,3) [12] | (4,4) [21] |
| 6 | \times [4] | (4,1) [8] | (2,2) [21] | | |
| 7 | (4,0) [8] | (1,1) [9] | | | |
| 8 | (2,0) [8] | | | | |
| 11 | (1,0) [22] | | | | |

Table 1: The girth and the (k, j)-colorability of planar graphs. The symbol "×" means that there exist non-(k, j)-colorable planar graphs for every k.

From the previous discussion, the following questions are natural:

Question 1.

- 1. Are planar graphs with girth 10 (1,0)-colorable?
- 2. Are planar graphs with girth 7 (3,0)-colorable?
- 3. Are planar graphs with girth 6 (1,1)-colorable?
- 4. Are planar graphs with girth 5 (4, 1)-colorable?
- 5. Are planar graphs with girth 5 (2,2)-colorable?

(d_1,\ldots,d_k) -coloring.

Finally we would like to mention two studies. Chang, Havet, Montassier, and Raspaud [10] gave some approximation results to Steinberg's Conjecture using (k, j, i)-colorings. Dorbec, Kaiser, Montassier, and Raspaud [14] studied the particular case of (d_1, \ldots, d_k) -coloring where the value of each d_i $(1 \le i \le k)$ is either 0 or some value d, making the link between (d, 0)-coloring [8] and (d, \ldots, d) -coloring [21].

The aim of this paper is to provide complexity results on the subject and to obtain non-colorable planar graphs showing that some above-mentioned results are optimal. Claim 2. There exist 2-degenerate planar graphs that are:

1. non-(k, k)-colorable with girth 4, for every $k \ge 0$,

- 2. non-(3,1)-colorable with girth 5,
- 3. non-(k, 0)-colorable with girth 6,

4. non-(2,0)-colorable with girth 7.

Claim 2.4 shows that the (2,0)-colorability of planar graphs with girth at least 8 [8] is a tight result. Claim 2.3 has been obtained in [?] and the corresponding graph is depicted in Figure 1.

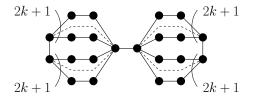

Figure 1: A non-(k, 0)-colorable planar graph with girth 6 [4].

Theorem 3. Let k, j, and g be fixed integers such that $(k, j) \neq (0, 0)$ and $g \ge 3$. Either every planar graph with girth at least g is (k, j)-colorable or it is NP-complete to determine whether a planar graph with girth at least g is (k, j)-colorable.

Theorem 4. Let k be a fixed integer. It is NP-complete to determine whether a 3-degenerate planar graph that is either (0,0,0)-colorable or non-(k,k,1)colorable is (0,0,0)-colorable.

We construct a non-(k, k)-colorable planar graph with girth 4 in Section 2, a non-(3, 1)-colorable planar graph with girth 5 in Section 3, and a non-(2, 0)-colorable planar graph with girth 7 in Section 4. We prove Theorem 3 in Section 5 and we prove Theorem 4 in Section 6.

Notation.

In the following, when we consider a (d_1, \ldots, d_k) -coloring of a graph G, we color the vertices of V_i with color d_i for $1 \leq i \leq k$: for example in a (3,0)-coloring, we will use color 3 to color the vertices of V_1 inducing a subgraph with maximum degree 3 and use color 0 to color the vertices of V_2 inducing a stable set. A vertex is said to be *colored* i^j if it is colored i and has j neighbors colored i, that is, it has degree j in the subgraph induced by its color. A vertex is *saturated* if it is colored i^i , that is, if it has maximum degree in the subgraph induced by its color. A vertex k-vertex, k-vertex, k-vertex) is a vertex of degree k (resp. k-face). A k-vertex (resp. k^- -vertex, k^+ -vertex) is a vertex of degree k (resp. at most k, at least k). The minimum degree of a graph G is denoted by $\delta(G)$.

2 A non-(k, k)-colorable planar graph with girth 4

For every $k \ge 0$, we construct a non-(k, k)-colorable planar graph J_4 with girth 4. Let $H_{x,y}$ be a copy of $K_{2,2k+1}$, as depicted in Figure 2. In any (k, k)coloring of $H_{x,y}$, the vertices x and y must receive the same color. We obtain J_4 from a vertex u and a star S with center v_0 and k + 1 leaves v_1, \ldots, v_{k+1} by linking u to every vertex v_i with a copy H_{u,v_i} of $H_{x,y}$. The graph J_4 is not (k, k)-colorable: by the property of $H_{x,y}$, every vertex v_i should get the same color as u. This gives a monochromatic S, which is forbidden. Notice that J_4 is a planar graph with girth 4 and is 2-degenerate.

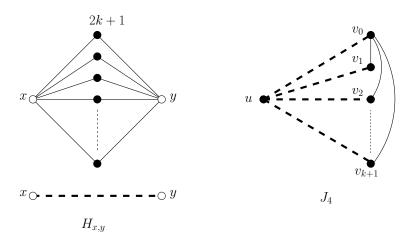

Figure 2: A non-(k, k)-colorable planar graph with girth 4.

3 A non-(3, 1)-colorable planar graph with girth 5

We construct a non-(3, 1)-colorable planar graph J_5 with girth 5. Consider the graph $H_{x,y}$ depicted in Figure 3. If x and y are colored 3 but have no neighbor colored 3, then it is not possible to extend this partial coloring to $H_{x,y}$. Now, we construct the graph S_z as follows. Let z be a vertex and $t_1t_2t_3$ be a path on three vertices. Take 21 copies H_{x_i,y_j} of $H_{x,y}$ with $1 \leq i \leq 7$ and $1 \leq j \leq 3$. Identify every x_i with z and identify every y_i with t_i . Finally, we obtain J_5 from three copies S_{z_1} , S_{z_2} , and S_{z_3} of S_z by adding the edges z_1z_2 and z_2z_3 (Figure 3). Notice that J_5 is planar with girth 5 and is 2-degenerate. Let us show that J_5 is not (3, 1)-colorable. In every (3, 1)-coloring of J_5 , the path $z_1z_2z_3$ contains a vertex z colored 3. Since z (resp. t) has at most 3 neighbors colored 3, one of the seven copies of $H_{x,y}$ between z and t, does not contain a neighbor of z or t colored 3. This copy of $H_{x,y}$ is not (3, 1)-colorable, and thus J_5 is not (3, 1)-colorable.

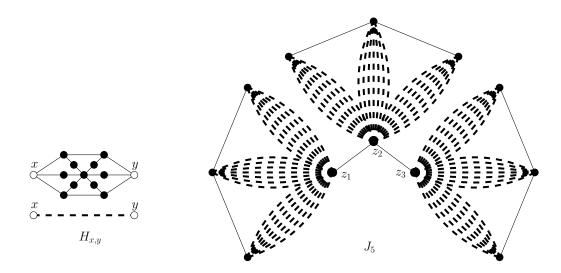

Figure 3: A non-(3, 1)-colorable planar graph with girth 5.

4 A non-(2,0)-colorable planar graph with girth 7

We construct of a non-(2, 0)-colorable planar graph J_7 with girth 7. Consider the graphs $T_{x,y,z}$ and S in Figure 4. If the vertices x, y, and z of $T_{x,y,z}$ are colored 2 and have no neighbor colored 2, then w is colored 2². Suppose that the vertices a, b, c, d, e, f, g of S are respectively colored 2, 0, 2, 2, 2, 2, 0, and that a has no neighbor colored 2. Using successively the property of $T_{x,y,z}$, we have that w_1, w_2 , and w_3 must be colored 2². It follows that w_4 is colored 0, w_5 is colored 2, and so w_6 is colored 2². Again, by the property of $T_{x,y,z}, w_7$ must be colored 2². Finally, w_8 must be colored 0 and there is no choice of color for w_9 . Hence, such a coloring of the outer 7-cycle *abcdefg* cannot be extended.

The graph H_z depicted on the left of Figure 5 is obtained as follows. We link a vertex z to every vertex of a 7-cycle $v_1 \ldots v_7$ with a path of three edges. Then we embed the graph S in every 7-face F_i $(1 \le i \le 7)$ incident to z by identifying the outer 7-cycle of S with the 7-cycle of F_i such that a is identified to z. Finally, the graph J_7 depicted on the right of Figure 5 is obtained from two adjacent vertices u and v and six copies H_{z_1}, \ldots, H_{z_6} of H_z by identifying z_1, z_2, z_3 with u and z_4, z_5, z_6 with v. Notice that J_7 is planar with has girth 7. Let us prove that J_7 is not (2, 0)-colorable.

- We assume that u is colored 2 since u and v cannot be both colored 0.
- In one of the three copies of H_z attached to u, say H_{z_1} , u has no neighbor colored 2.
- Since a 7-cycle is not 2-colorable, the 7-cycle $v_1 \ldots v_7$ of H_{z_1} contains a monochromatic edge colored 2, say $v_1 v_2$.
- The coloring of the face F_2 cannot be extended to the copy of S embedded in F_2 .

5 NP-completeness of (k, j)-colorings

Let $g_{k,j}$ be the largest integer g such that there exists a planar graph with girth g that is not (k, j)-colorable. Because of large odd cycles, $g_{0,0}$ is not defined. For $(k, j) \neq (0, 0)$, we have $4 \leq g_{k,j} \leq 10$ by the example in Figure 2 and the result that planar graphs with girth at least 11 are (0, 1)-colorable [22]. We prove this equivalent form of Theorem 3: **Theorem 5.** Let k and j be fixed integers such that $(k, j) \neq (0, 0)$. It is NPcomplete to determine whether a planar graph with girth $g_{k,j}$ is (k, j)-colorable.

Let us define the partial order \leq . Let $n_3(G)$ be the number of 3⁺-vertices in G. For any two graphs G_1 and G_2 , we have $G_1 \prec G_2$ if and only if at least one of the following conditions holds:

- $|V(G_1)| < |V(G_2)|$ and $n_3(G_1) \le n_3(G_2)$.
- $n_3(G_1) < n_3(G_2)$.

Note that the partial order \leq is well-defined and is a partial linear extension of the subgraph poset. The following lemma is useful.

Lemma 6. Let k and j be fixed integers such that $(k, j) \neq (0, 0)$. There exists a planar graph $G_{k,j}$ with girth $g_{k,j}$, minimally non-(k, j)-colorable for the subgraph order, such that $\delta(G_{k,j}) = 2$.

Proof. We have $\delta(G_{k,j}) \ge 2$, since a non-(k, j)-colorable graph that is minimal for the subgraph order does not contain a 1⁻-vertex. Suppose that for some pair (k, j), we construct a 2-degenerate non-(k, j)-colorable planar graph with girth $g_{k,j}$. Then this graph contains a (not necessarily proper) minimally non-(k, j)-colorable subgraph with minimum degree 2. Thus, we can prove the lemma for the following pairs (k, j) by using Claim 2.

- Pairs (k, j) such that $g_{k,j} \leq 4$: We actually have $g_{k,j} = 4$ by Claim 2.1.
- Pairs (k, j) such that $g_{k,j} \ge 6$: Indeed, a planar graph with girth at least 6 is 2-degenerate. In particular, Claim 2.3 shows that $g_{k,0} \ge 6$, so the lemma is proved for all pairs (k, 0).
- Pairs (k, 1) such that $1 \leq k \leq 3$: If $g_{k,j} \geq 6$, then we are in a previous case. Otherwise, we have $g_{k,j} = 5$ by Claim 2.2.

The remaining pairs satisfy $g_{k,j} = 5$. There are two types of remaining pairs (k, j):

- Type 1: $k \ge 4$ and j = 1.
- Type 2: $2 \leq j \leq k$.

Consider a planar graph G with girth 5 that is non-(k, j)-colorable and is minimal for the order \preceq . Suppose for contradiction that G does not contain a 2-vertex. Also, suppose that G contains a 3-vertex a adjacent to three 4⁻vertices a_1, a_2 , and a_3 . For colorings of type 1, we can extend to G a coloring of $G \setminus \{a\}$ by assigning to a the color of improperty at least 4. For colorings of type 2, we consider the graph G' obtained from $G \setminus \{a\}$ by adding three 2-vertices b_1, b_2 , and b_3 adjacent to, respectively, a_2 and a_3, a_1 and a_3, a_1 and a_2 . Notice that $G' \preceq G$, so G' admits a coloring c of type 2. We can extend to *G* the coloring of $G \setminus \{a\}$ induced by *c* as follows. If a_1 , a_2 , and a_3 have the same color, then we assign to *a* the other color. Otherwise, we assign to *a* the color that appears at least twice among the colors of b_1 , b_2 , and b_3 . Now, since *G* does not contain a 2-vertex nor a 3-vertex adjacent to three 4⁻-vertices, we have mad(G) $\geq \frac{10}{3}$. This can be seen using the discharging procedure such that the initial charge of each vertex is its degree and every 5⁺-vertex gives $\frac{1}{3}$ to each adjacent 3-vertex. The final charge of a 3-vertex is at least $3 + \frac{1}{3} = \frac{10}{3}$, the final charge of a 4-vertex is $4 > \frac{10}{3}$, and the final charge of a *k*-vertex with $k \geq 5$ is at least $k - k \times \frac{1}{3} = \frac{2k}{3} \geq \frac{10}{3}$. Now, mad(G) $\geq \frac{10}{3}$ contradicts the fact that *G* is a planar graph with girth 5, and this contradiction shows that *G* contains a 2-vertex.

We are ready to prove Theorem 5. The case of (1, 0)-coloring is proved in a stronger form which takes into account restrictions on both the girth and the maximum degree of the input planar graph [16].

Proof of the case $(k, 0), k \ge 2$.

We consider a graph $G_{k,0}$ as described in Lemma 6, which contains a path uxv where x is a 2-vertex. By minimality, any (k, 0)-coloring of $G_{k,0} \setminus \{x\}$ is such that u and v get distinct saturated colors. Let G be the graph obtained from $G_{k,0} \setminus \{x\}$ by adding three 2-vertices x_1, x_2 , and x_3 to create the path $ux_1x_2x_3v$. So any (k, 0)-coloring of G is such that x_2 is colored k^1 . To prove the NP-completeness, we reduce the (k, 0)-coloring problem to the (1, 0)-coloring problem. Let I be a planar graph with girth $g_{1,0}$. For every vertex s of I, add (k-1) copies of G such that the vertex x_2 of each copy is adjacent to s, to obtain the graph I'. By construction, I' is (k, 0)-colorable if and only if I is (1, 0)-colorable. Moreover, I' is planar, and since $g_{k,0} \leq g_{1,0}$, the girth of I' is $g_{k,0}$.

Proof of the case (1, 1).

By Claim 2.2 and [9], $g_{1,1}$ is either 5 or 6. There exist two independent proofs [17, 19] that (1, 1)-coloring is NP-complete for triangle-free planar graphs with maximum degree 4. We use a reduction from that problem to prove that (1, 1)-coloring is NP-complete for planar graphs with girth $g_{1,1}$. We consider a graph $G_{1,1}$ as described in Lemma 6, which contains a path uxv where x is a 2-vertex. By minimality, any (1, 1)-coloring of $G_{1,1} \setminus \{x\}$ is such that u and v get distinct saturated colors. Let G be the graph obtained from $G_{1,1} \setminus \{x\}$ by adding a vertex u' adjacent to u and a vertex v' adjacent to v. So any (1, 1)-coloring of G is such that u' and v' get distinct colors and u' (resp. v') has a color distinct from the color of its (unique) neighbor. We construct the graph $E_{a,b}$ from two vertices a and b and two copies of G such that a is adjacent to the vertices u' of both copies of G and b is adjacent to the vertices v' of both copies of G. There exists a (1, 1)-coloring of $E_{a,b}$ such that a and b have distinct colors and neither a nor b is saturated. There exists a (1, 1)-coloring of $E_{a,b}$ such that a and b have the same color. Moreover, in every (1, 1)-coloring of $E_{a,b}$ such that a and b have the same color, both a and b are saturated.

The reduction is as follows. Let I be a planar graph. For every edge (p,q) of I, replace (p,q) by a copy of $E_{a,b}$ such that a is identified with p and b is identified with q, to obtain the graph I'. By the properties of $E_{a,b}$, I is (1, 1)-colorable if and only if I' is (1, 1)-colorable. Moreover, I' is planar with girth $g_{1,1}$.

Proof of the case (k, j).

We consider a graph $G_{k,j}$ as described in Lemma 6, which contains a path uxv where x is a 2-vertex. By minimality, any (k, j)-coloring of $G_{k,j} \setminus \{x\}$ is such that u and v get distinct saturated colors. Let G be the graph obtained from $G_{k,j} \setminus \{x\}$ by adding a vertex u' adjacent to u and a vertex v' adjacent to v. So any (k, j)-coloring of G is such that u' and v' get distinct colors and u' (resp. v') has a color distinct from the color of its (unique) neighbor. Let $t = \min(k-1, j)$. To prove the NP-completeness, we reduce the (k, j)-coloring to the (k-t, j-t)-coloring. Thus the case (k, k) reduces to the case (1, 1) which is NP-complete, and the case (k, j) with j < k reduces to the case (k - j, 0) which is NP-complete. The reduction is as follows. Let I be a planar graph with girth $g_{k-t,j-t}$. For every vertex s of I, add t copies of G such that the vertices u' and v' of each copy is adjacent to s, to obtain the graph I'. By construction, I is (k - t, j - t)-colorable if and only if I' is (k, j)-colorable. Moreover, I' is planar, and since $g_{k,j} \leq g_{k-t,j-t}$, the girth of I' is $g_{k,j}$.

6 NP-completeness of (k, j, i)-colorings

In this section, we prove Theorem 4 using a reduction from 3-colorability, i.e. (0, 0, 0)-colorability, which is NP-complete for planar graphs [18].

Let E be the graph depicted in Fig 6. The graph E' is obtained from 2k-1 copies of E by identifying the edge ab of all copies. Take 4 copies E'_1 , E'_2 , E'_3 , and E'_4 of E' and consider a triangle T formed by the vertices y_0 , x_0 , x_1 in one copy of E in E'_1 . The graph E'' is obtained by identifying the edge y_0x_0 (resp. y_0x_1 , x_0x_1) of T with the edge ab of E'_2 (resp. E'_3 , E'_4). The edge ab of E'_1 is then said to be the edge ab of E''_2 .

Lemma 7.

- 1. E'' admits a (0, 0, 0)-coloring.
- 2. E' does not admit a (k, k, 1)-coloring such that a and b have a same color of improperty k.
- 3. E'' does not admit a (k, k, 1)-coloring such that a and b have the same color.

Proof.

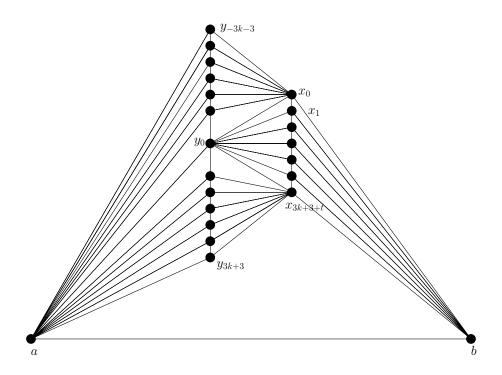

Figure 6: The graph E. We take t = 0 if k is odd and t = 1 if k is even, so that 3k + 3 + t is even.

- 1. The following (0,0,0)-coloring c of E is unique up to permutation of colors: $c(a) = c(x_i) = 1$ for even i, $c(b) = c(y_i) = 2$ for even i, and $c(x_i) = c(y_i) = 3$ for odd i. This coloring can be extended into a (0,0,0)-coloring of E' and E''.
- 2. Let k_1 , k_2 , and 1 denote the colors in a potential (k, k, 1)-coloring c of E' such that $c(a) = c(b) = k_1$. By the pigeon-hole principle, one of the 2k-1 copies of E in E', say E^* , is such that a and b are the only vertices with color k_1 . So, one of the vertices x_0 , y_0 , and x_{3k+3+t} in E^* must get color k_2 since they cannot all get color 1. We thus have a vertex $v_1 \in \{a, b\}$ colored k_1 and vertex $v_2 \in \{x_0, y_0, x_{3k+3+t}\}$ colored k_2 in E^* which both dominate a path on at least 3k + 3 vertices. This path contains no vertex colored k_1 since it is in E^* . Moreover, it contains at most k vertices colored k_2 . On the other hand, every set of 3 consecutive vertices in this path contains at least one vertex colored k_2 , so it contains at least $\frac{3k+3}{3} = k + 1$ vertices colored k_2 . This contradiction shows that E' does not admit a (k, k, 1)-coloring such that a and b have a same color of improperty k.
- 3. By the previous item and by construction of E'', if E'' admits a (k, k, 1)coloring c such that c(a) = c(b), then c(a) = c(b) = 1. We thus have
 that $\{c(y_0), c(x_0), c(x_1)\} \subset \{k_1, k_2\}$. This implies that at least one edge
 of the triangle T is monochromatic with a color of improperty k. By

THE ELECTRONIC JOURNAL OF COMBINATORICS 22 (2015), #P00

the previous item, the coloring c cannot be extended to the copy of E' attached to that monochromatic edge. This shows that E'' does not admit a (k, k, 1)-coloring such that a and b have the same color.

For every fixed integer k, we give a polynomial construction that transforms every planar graph G into a planar graph G' such that G' is (0, 0, 0)-colorable if G is (0, 0, 0)-colorable and G' is not (k, k, 1)-colorable otherwise. The graph G' is obtained from G by identifying every edge of G with the edge ab of a copy of E''. If G is (0, 0, 0)-colorable, then this coloring can be extended into a (0, 0, 0)-coloring of G' by Lemma 7.1. If G is not (0, 0, 0)-colorable, then every (k, k, 1)-coloring G contains a monochromatic edge uv, and then the copy of E'' corresponding to uv (and thus G') does not admit a (k, k, 1)-coloring by Lemma 7.3. The instance graph G in the proof that (0, 0, 0)-coloring is NPcomplete [18] is 3-degenerate. Then by construction, G' is also 3-degenerate.
