

# SPLIT DECOMPOSITION AND CIRCLE GRAPH RECOGNITION IN QUASI-LINEAR TIME

**Christophe Paul**

CNRS - LIRMM - Université Montpellier II, France

March 25, 2009

Joint work with **D. Corneil** (U. of Toronto), **E. Gioan** (CNRS LIRMM)  
and **M. Tedder** (U. of Toronto)

## Graph-labeled tree (GLT)

- ▶ a pair  $(T, \mathcal{F})$  with  $T$  a tree and  $\mathcal{F}$  a set of graphs
- ▶ each node  $v$  of degree  $k$  of  $T$  is labelled by a graph  $G_v \in \mathcal{F}$
- ▶ a bijection  $\rho_v$  from the tree-edges incident to  $v$  to  $V(G_v)$

## Accessibility graph of a GLT

Given a GLT  $(T, \mathcal{F})$ , define the graph  $G(T, \mathcal{F})$  with

- ▶ vertex set of  $G(T, \mathcal{F}) =$  set of leaves of  $T$
- ▶  $xy$  is an edge iff  $\rho_v(uv)\rho_v(vw) \in E(G_v)$   
for all tree-edges  $uv, vw$  on the  $x, y$ -path in  $T$

**A split in a graph**  $G = (V, E)$  is a bipartition  $(A, B)$  of  $V$  st.

- ▶  $|A| \geq 2$ ,  $|B| \geq 2$  and
- ▶ for  $x \in A$ ,  $y \in B$ ,  $xy \in E$  iff  $x \in N(B)$  and  $y \in N(A)$

Every **edge** of a GLT defines a **split**

### Theorem [Cunningham'82 reformulated]

For any connected graph  $G$ , there exists a unique graph-labelled tree  $ST(G) = (T, \mathcal{F})$  with a minimum number of nodes such that

- ▶  $G = G(T, \mathcal{F})$ ,
- ▶ any graph of  $\mathcal{F}$  is **prime** or **degenerate**.

Prime

Degenerate

## Vertex incremental characterization

A vertex  $x$  is added to a graph  $G = (V, E)$  with neighbors  $S \subseteq V$ .  
( $S$  is represented in red)

► How to compute the split tree  $ST(G + (x, S))$  from  $ST(G)$  ?

## States of marker vertices

Let  $q$  be marker vertex (or a leaf)

Let  $L(q)$  be the set of leaves  $l$  such that the path between  $l$  and  $q$  contains the edge of the tree associated with  $q$

## States of marker vertices

Let  $q$  be marker vertex (or a leaf)

Let  $L(q)$  be the set of leaves  $l$  such that the path between  $l$  and  $q$  contains the edge of the tree associated with  $q$

- ▶  $q$  is **empty** if  $L(q) \cap S = \emptyset$

## States of marker vertices

Let  $q$  be marker vertex (or a leaf)

Let  $L(q)$  be the set of leaves  $l$  such that the path between  $l$  and  $q$  contains the edge of the tree associated with  $q$

- ▶  $q$  is **empty** if  $L(q) \cap S = \emptyset$
- ▶  $q$  is **perfect** if every leaf in  $L(q) \cap S$  is accessible from  $q$

## States of marker vertices

Let  $q$  be marker vertex (or a leaf)

Let  $L(q)$  be the set of leaves  $l$  such that the path between  $l$  and  $q$  contains the edge of the tree associated with  $q$

- ▶  $q$  is **empty** if  $L(q) \cap S = \emptyset$
- ▶  $q$  is **perfect** if every leaf in  $L(q) \cap S$  is accessible from  $q$
- ▶  $q$  is **mixed** otherwise

## Vertex Incremental Characterization

The split tree of  $G + (x, S)$  is obtained from  $ST(G)$  by 3 cases:

- ▶ 1 -  $T$  has an edge  $e$  whose extremities are perfect

## Vertex Incremental Characterization

The split tree of  $G + (x, S)$  is obtained from  $ST(G)$  by 3 cases:

- ▶ 1 -  $T$  has an edge  $e$  whose extremities are perfect

## Vertex Incremental Characterization

The split tree of  $G + (x, S)$  is obtained from  $ST(G)$  by 3 cases:

- ▶ 1 -  $T$  has an edge  $e$  whose extremities are perfect
- ▶ 2 -  $T$  has an edge  $e$ , one extremity of which is perfect and the other empty

## Vertex Incremental Characterization

The split tree of  $G + (x, S)$  is obtained from  $ST(G)$  by 3 cases:

- ▶ 1 -  $T$  has an edge  $e$  whose extremities are perfect
- ▶ 2 -  $T$  has an edge  $e$ , one extremity of which is perfect and the other empty
- ▶ 3 -  $T$  has a **fully-mixed** node  $u$

every marker vertex adjacent to the node  $u$  is mixed

## Vertex Incremental Characterization

The split tree of  $G + (x, S)$  is obtained from  $ST(G)$  by 3 cases:

- ▶ 1 -  $T$  has an edge  $e$  whose extremities are perfect
- ▶ 2 -  $T$  has an edge  $e$ , one extremity of which is perfect and the other empty
- ▶ 3 -  $T$  has a **fully-mixed** node  $u$  (the set of fully-mixed nodes is a subtree of  $T$ )

## Vertex Incremental Characterization

The split tree of  $G + (x, S)$  is obtained from  $ST(G)$  by 3 cases:

- ▶ 1 -  $T$  has an edge  $e$  whose extremities are perfect
- ▶ 2 -  $T$  has an edge  $e$ , one extremity of which is perfect and the other empty
- ▶ 3 -  $T$  has a **fully-mixed** node  $u$  (the set of fully-mixed nodes is a subtree of  $T$ )

## Vertex Incremental Characterization

The split tree of  $G + (x, S)$  is obtained from  $ST(G)$  by 3 cases:

- ▶ 1 -  $T$  has an edge  $e$  whose extremities are perfect
- ▶ 2 -  $T$  has an edge  $e$ , one extremity of which is perfect and the other empty
- ▶ 3 -  $T$  has a **fully-mixed** node  $u$  (the set of fully-mixed nodes is a subtree of  $T$ )

**Theorem:** the incremental split decomposition algorithm runs in  $O((n + m)\alpha(n, m))$

### Ingredients for the complexity analysis

- ▶ the vertex insertion ordering has to be a **LexBFS** ordering
- ▶ a carefully amortizing analysing based on **discharging techniques**

### Previous results

- ▶ [Cunningham 1982]  $O(nm)$
- ▶ [Ma, Spinrad 1994]  $O(n^2)$
- ▶ [Dahlhaus 2000]  $O(n + m)$  (tough !)
- ▶ [Charbit, De Montgolfier, Raffinot 2009]  $O(n + m)$  (today)

## Application to circle graphs recognition

- ▶ A **circle** graph is the intersection graph of chords in a circle.

## Application to circle graphs recognition

- ▶ A **circle** graph is the intersection graph of chords in a circle.
- ▶ A graph is **circle** iff all the prime nodes of its split tree are circle graphs

## Application to circle graphs recognition

- ▶ A **circle** graph is the intersection graph of chords in a circle.
- ▶ A graph is **circle** iff all the prime nodes of its split tree are circle graphs
- ▶ A circle graph is prime for the split decomposition iff it has a unique (up to mirror) realizer

## Application to circle graphs recognition

- ▶ A **circle** graph is the intersection graph of chords in a circle.
- ▶ A graph is **circle** iff all the prime nodes of its split tree are circle graphs
- ▶ A circle graph is prime for the split decomposition iff it has a unique (up to mirror) realizer

## Extreme chord - vertex

A vertex  $x$  is **extreme** if its chord  $c(x)$  cut the realizer in a way that the chords of all the non-neighbors of  $x$  are either all on the right or all on the left of  $c(x)$ .

## First LexBFS Lemma

Let  $G$  be a circle graph and  $\sigma$  be a LexBFS ordering of  $G$  ending at  $x$ . Then there exists a realizer of  $G$  in which the chord  $c(x)$  is extreme.

## First LexBFS Lemma

Let  $G$  be a circle graph and  $\sigma$  be a LexBFS ordering of  $G$  ending at  $x$ . Then there exists a realizer of  $G$  in which the chord  $c(x)$  is extreme.

- ▶ **Consequence:** we know in constant time where to insert  $x$  in a given realizer of  $G$ .
- ▶ **But** many realizers unless prime

## A second LexBFS Lemma

Let  $\sigma$  be a LexBFS ordering of  $G = G_S(T, \mathcal{F})$ . The "induced" ordering  $\sigma_U$  of the marker vertices of  $G_U$  is a LexBFS ordering.

## A second LexBFS Lemma

Let  $\sigma$  be a LexBFS ordering of  $G = G_S(T, \mathcal{F})$ . The "induced" ordering  $\sigma_u$  of the marker vertices of  $G_u$  is a LexBFS ordering.

- ▶ **consequence:** we can apply the first LexBFS lemma on each node of the split tree.

## A second LexBFS Lemma

Let  $\sigma$  be a LexBFS ordering of  $G = G_S(T, \mathcal{F})$ . The "induced" ordering  $\sigma_u$  of the marker vertices of  $G_u$  is a LexBFS ordering.

- ▶ **consequence:** we can apply the first LexBFS lemma on each node of the split tree.
- ▶ **what remains to do ?**  
handle the merging of the fully-mixed nodes before insertion.

## Circle graph recognition - ingredients

1. Insert vertices with respect to a LexBFS ordering.
2. Maintain the split tree in which each prime node are represented by its realizer.
3. Proceed the merging step on the realizers of the fully-mixed nodes according to the LexBFS Lemmas.  
⇒ need some small tricks for realizer representation

## Circle graph recognition - ingredients

1. Insert vertices with respect to a LexBFS ordering.
2. Maintain the split tree in which each prime node are represented by its realizer.
3. Proceed the merging step on the realizers of the fully-mixed nodes according to the LexBFS Lemmas.  
⇒ need some small tricks for realizer representation

**Theorem:** The circle graph recognition problem can be solved in time  $O((n + m)\alpha(n, m))$

→ Previous complexity:  $O(n^2)$  [Spinrad, J. of Alg. (16), 1994]
