The Recognition of Tolerance and Bounded Tolerance Graphs

George B. Mertzios† Ignasi Sau‡ Shmuel Zaks§

Abstract

Tolerance graphs model interval relations in such a way that intervals can tolerate a certain degree of overlap without being in conflict. This subclass of perfect graphs has been extensively studied, due to both its interesting structure and its numerous applications (in bioinformatics, constrained-based temporal reasoning, resource allocation, and scheduling problems, among others). Several efficient algorithms for optimization problems that are NP-hard in general graphs have been designed for tolerance graphs. In spite of this, the recognition of tolerance graphs – namely, the problem of deciding whether a given graph is a tolerance graph – as well as the recognition of their main subclass of bounded tolerance graphs, have been the most fundamental open problems on this class of graphs (cf. the book on tolerance graphs [15]) since their introduction in 1982 [12]. In this article we prove that both recognition problems are NP-complete, even in the case where the input graph is a trapezoid graph. The presented results are surprising because, on the one hand, most subclasses of perfect graphs admit polynomial recognition algorithms and, on the other hand, bounded tolerance graphs were believed to be efficiently recognizable as they are a natural special case of trapezoid graphs (which can be recognized in polynomial time) and share a very similar structure with them. For our reduction we extend the notion of an acyclic orientation of permutation and trapezoid graphs. Our main tool is a new algorithm that uses vertex splitting to transform a given trapezoid graph into a permutation graph, while preserving this new acyclic orientation property. This method of vertex splitting is of independent interest; very recently, it has been proved a powerful tool also in the design of efficient recognition algorithms for other classes of graphs [23].

Keywords: Tolerance graphs, bounded tolerance graphs, recognition, vertex splitting, NP-complete, trapezoid graphs, permutation graphs.

1 Introduction

1.1 Tolerance graphs and related graph classes

A simple undirected graph \( G = (V, E) \) on \( n \) vertices is a tolerance graph if there exists a collection \( I = \{I_i \mid i = 1, 2, \ldots, n\} \) of closed intervals on the real line and a set \( t = \{t_i \mid i = 1, 2, \ldots, n\} \) of positive numbers, such that for any two vertices \( v_i, v_j \in V \), \( v_iv_j \in E \) if and only if \( |I_i \cap I_j| \geq \min\{t_i, t_j\} \). The pair \( (I, t) \) is called a tolerance representation of \( G \). If \( G \) has a tolerance representation \( (I, t) \), such that \( t_i \leq |I_i| \) for every \( i = 1, 2, \ldots, n \), then \( G \) is called a bounded tolerance graph and \( (I, t) \) a bounded tolerance representation of \( G \).

Tolerance graphs were introduced in [12], in order to generalize some of the well known applications of interval graphs. The main motivation was in the context of resource allocation

and scheduling problems, in which resources, such as rooms and vehicles, can tolerate sharing among users [15]. If we replace in the definition of tolerance graphs the operator min by the operator max, we obtain the class of max-tolerance graphs. Both tolerance and max-tolerance graphs find in a natural way applications in biology and bioinformatics, as in the comparison of DNA sequences from different organisms or individuals [19], by making use of a software tool like BLAST [1]. Tolerance graphs find numerous other applications in constrained-based temporal reasoning, data transmission through networks to efficiently scheduling aircraft and crews, as well as contributing to genetic analysis and studies of the brain [14,15]. This class of graphs has attracted many research efforts [2,4,8,13–15,17,20,24,26], as it generalizes in a natural way both interval graphs (when all tolerances are equal) and permutation graphs (when $t_i = |I_i|$ for every $i = 1, 2, \ldots, n$) [12]. For a detailed survey on tolerance graphs we refer to [15].

A graph is perfect if the chromatic number of every induced subgraph equals the clique number of that subgraph. Several difficult combinatorial problems can be solved efficiently, i.e. in polynomial time, on the class of perfect graphs, such as minimum coloring, maximum clique, and independent set [16]. Thus, since the class of tolerance graphs is a subclass of perfect graphs [13], there exist polynomial algorithms for these problems on tolerance and bounded tolerance graphs as well. In spite of this, faster algorithms have been designed for tolerance and bounded tolerance graphs, which exploit their special structure [14,15,24,26].

A comparability graph is a graph which can be transitively oriented. A co-comparability graph is a graph whose complement is a comparability graph. A trapezoid (resp. parallel-gram and permutation) graph is the intersection graph of trapezoids (resp. parallelograms and line segments) between two parallel lines $L_1$ and $L_2$ [10]. Such a representation with trapezoids (resp. parallelograms and line segments) is called a trapezoid (resp. parallel-gram and permutation) representation of this graph. A graph is bounded tolerance if and only if it is a parallel-gram graph [2,21]. Permutation graphs are a strict subset of parallel-gram graphs [3]. Furthermore, parallel-gram graphs are a strict subset of trapezoid graphs [28], and both are subsets of co-comparability graphs [10,15]. On the contrary, tolerance graphs are not even co-comparability graphs [10,15]. Recently, we have presented in [24] a natural intersection model for general tolerance graphs, given by parallelepips in the three-dimensional space. This representation generalizes the parallel-gram representation of bounded tolerance graphs, and has been used to improve the time complexity of minimum coloring, maximum clique, and weighted independent set algorithms on tolerance graphs [24].

Although tolerance and bounded tolerance graphs have been studied extensively, the recognition problems for both these classes have been the most fundamental open problems since their introduction in 1982 [5,10,15]. Therefore, all existing algorithms assume that, along with the input tolerance graph, a tolerance representation of it is given. The only result about the complexity of recognizing tolerance and bounded tolerance graphs is that they have a (non-trivial) polynomial sized tolerance representation, hence the problems of recognizing tolerance and bounded tolerance graphs are in the class NP [17]. Recently, a linear time recognition algorithm for the subclass of bipartite tolerance graphs has been presented in [5]. Furthermore, the class of trapezoid graphs (which strictly contains parallelogram, i.e. bounded tolerance, graphs [28]) can be also recognized in polynomial time [22,23,30]. On the other hand, the recognition of max-tolerance graphs is known to be NP-hard [19]. Unfortunately, the structure of max-tolerance graphs differs significantly from that of tolerance graphs (max-tolerance graphs are not even perfect, as they can contain induced $C_5$’s [19]), so the technique used in [19] does not carry over to tolerance graphs.

Since very few subclasses of perfect graphs are known to be NP-hard to recognize (for instance, perfectly orderable graphs [25] or EPT graphs [11]), it was believed that the recognition of tolerance graphs was in P. Furthermore, as bounded tolerance graphs are equivalent
to parallelogram graphs [2, 21], which constitute a natural subclass of trapezoid graphs and have a very similar structure, it was plausible that their recognition was also in P.

1.2 Our contribution

In this article, we establish the complexity of recognizing tolerance and bounded tolerance graphs. Namely, we prove that both problems are surprisingly NP-complete, by providing a reduction from the monotone-Not-All-Equal-3-SAT (monotone-NAE-3-SAT) problem. Consider a boolean formula \( \phi \) in conjunctive normal form with three literals in every clause (3-CNF), which is monotone, i.e. no variable is negated. The formula \( \phi \) is called NAE-satisfiable if there exists a truth assignment of the variables of \( \phi \), such that every clause has at least one true variable and one false variable. Given a monotone 3-CNF formula \( \phi \), we construct a trapezoid graph \( H_\phi \), which is parallelogram, i.e. bounded tolerance, if and only if \( \phi \) is NAE-satisfiable. Moreover, we prove that the constructed graph \( H_\phi \) is tolerance if and only if it is bounded tolerance. Thus, since the recognition of tolerance and of bounded tolerance graphs are in the class NP [17], it follows that both problems are NP-complete. Actually, our results imply that the recognition problems remain NP-complete even if the given graph is trapezoid, since the constructed graph \( H_\phi \) is trapezoid.

For our reduction we extend the notion of an acyclic orientation of permutation and trapezoid graphs. Our main tool is a new algorithm that transforms a given trapezoid graph into a permutation graph by splitting some specific vertices, while preserving this new acyclic orientation property. One of the main advantages of this algorithm is that the constructed permutation graph does not depend on any particular trapezoid representation of the input graph \( G \). Moreover, this approach based on splitting vertices has already been proven useful for the design of polynomial recognition algorithms for other classes of graphs [23].

Organization of the paper. We first present in Section 2 several properties of permutation and trapezoid graphs, as well as the algorithm Split-\( U \), which constructs a permutation graph from a trapezoid graph. In Section 3 we present the reduction of the monotone-NAE-3-SAT problem to the recognition of bounded tolerance graphs. In Section 4 we prove that this reduction can be extended to the recognition of general tolerance graphs. Finally, we discuss the presented results and further research directions in Section 5.

2 Trapezoid graphs and representations

In this section we first introduce (in Section 2.1) the notion of an acyclic representation of permutation and of trapezoid graphs. This is followed (in Section 2.2) by some structural properties of trapezoid graphs, which will be used in the sequel for the splitting algorithm Split-\( U \). Given a trapezoid graph \( G \) and a vertex subset \( U \) of \( G \) with certain properties, this algorithm constructs a permutation graph \( G^\#(U) \) with \( 2|U| \) vertices, which is independent on any particular trapezoid representation of the input graph \( G \).

Notation. We consider in this article simple undirected and directed graphs with no loops or multiple edges. In an undirected graph \( G \), the edge between vertices \( u \) and \( v \) is denoted by \( uv \), and in this case \( u \) and \( v \) are said to be adjacent in \( G \). If the graph \( G \) is directed, we denote by \( uv \) the arc from \( u \) to \( v \). Given a graph \( G = (V, E) \) and a subset \( S \subseteq V \), \( G[S] \) denotes the induced subgraph of \( G \) on the vertices in \( S \), and we use \( E[S] \) to denote \( E(G[S]) \). Whenever we deal with a trapezoid (resp. permutation and bounded tolerance, i.e. parallelogram) graph, we will consider without loss of generality a trapezoid (resp. permutation and parallelogram) representation, in which all endpoints of the trapezoids (resp. line segments
and parallelograms) are distinct [9,15,18]. Given a permutation graph \( P \) along with a permutation representation \( R \), we may not distinguish in the following between a vertex of \( P \) and the corresponding line segment in \( R \), whenever it is clear from the context. Furthermore, with a slight abuse of notation, we will refer to the line segments of a permutation representation just as lines.

2.1 Acyclic permutation and trapezoid representations

Let \( P = (V, E) \) be a permutation graph and \( R \) be a permutation representation of \( P \). For a vertex \( u \in V \), denote by \( \theta_R(u) \) the angle of the line of \( u \) with \( L_2 \) in \( R \). The class of permutation graphs is the intersection of comparability and co-comparability graphs [10]. Thus, given a permutation representation \( R \) of \( P \), we can define two partial orders \((V, \ll_R)\) and \((V, \ll_R)\) on the vertices of \( P \) [10]. Namely, for two vertices \( u \) and \( v \) of \( G \), \( u \ll_R v \) if and only if \( uv \in E \) and \( \theta_R(u) < \theta_R(v) \), while \( u \ll_R v \) if and only if \( uv \not\in E \) and \( u \) lies to the left of \( v \) in \( R \). The partial order \((V, \ll_R)\) implies a transitive orientation \( \Phi_R \) of \( P \), such that \( uv \in \Phi_R \) whenever \( u \ll_R v \).

Let \( G = (V, E) \) be a trapezoid graph, and \( R \) be a trapezoid representation of \( G \), where for any vertex \( u \in V \), the trapezoid corresponding to \( u \) in \( R \) is denoted by \( T_u \). Since trapezoid graphs are also co-comparability graphs [10], we can similarly define the partial order \((V, \ll_R)\) on the vertices of \( G \), such that \( u \ll_R v \) if and only if \( uv \not\in E \) and \( T_u \) lies to the left of \( T_v \) in \( R \). In this case, we may denote also \( T_u \ll_R T_v \), instead of \( u \ll_R v \).

In a given trapezoid representation \( R \) of a trapezoid graph \( G \), we denote by \( l(T_u) \) and \( r(T_u) \) the left and right line of \( T_u \) in \( R \), respectively. Similarly to the case of permutation graphs, we use the relation \( \ll_R \) for the lines \( l(T_u) \) and \( r(T_v) \), e.g. \( l(T_u) \ll_R r(T_v) \) means that the line \( l(T_u) \) lies to the left of the line \( r(T_v) \) in \( R \). Moreover, if the trapezoids of all vertices of a subset \( S \subseteq V \) lie completely to the left (resp. right) of the trapezoid \( T_u \) in \( R \), we write \( R(S) \ll_R T_u \) (resp. \( T_u \ll_R R(S) \)). Note that there are several trapezoid representations of a particular trapezoid graph \( G \). Given one such representation \( R \), we can obtain another one \( R' \) by vertical axis flipping of \( R \), i.e. \( R' \) is the mirror image of \( R \) along an imaginary line perpendicular to \( L_1 \) and \( L_2 \). Moreover, we can obtain another representation \( R'' \) of \( G \) by horizontal axis flipping of \( R \), i.e. \( R'' \) is the mirror image of \( R \) along an imaginary line parallel to \( L_1 \) and \( L_2 \). We will use extensively these two basic operations throughout the article.

**Definition 1** Let \( P \) be a permutation graph with \( 2n \) vertices \( \{u_1^1, u_2^1, u_3^2, \ldots, u_n^1, u_n^2\} \). Let \( R \) be a permutation representation and \( \Phi_R \) be the corresponding transitive orientation of \( P \). The simple directed graph \( F_R \) is obtained by merging \( u_i^1 \) and \( u_i^2 \) into a single vertex \( u_i \), for every \( i = 1, 2, \ldots, n \), where the arc directions of \( F_R \) are implied by the corresponding directions in \( \Phi_R \). Then,

1. \( R \) is an acyclic permutation representation with respect to \( \{u_1^1, u_1^2\} \), if \( F_R \) has no directed cycle,

2. \( P \) is an acyclic permutation graph with respect to \( \{u_1^1, u_1^2\} \), if \( P \) has an acyclic representation \( R \) with respect to \( \{u_1^1, u_1^2\} \).

In Figure 1 we show an example of a permutation graph \( P \) with six vertices in Figure 1(a), a permutation representation \( R \) of \( P \) in Figure 1(b), the transitive orientation \( \Phi_R \) of \( P \) in Figure 1(c), and the corresponding simple directed graph \( F_R \) in Figure 1(d). In the figure, the pairs \( \{u_i^1, u_i^2\} \) are grouped inside ellipses. In this example, \( R \) is not an acyclic permutation representation with respect to \( \{u_1^1, u_1^2\} \), since \( F_R \) has a directed cycle of length

\[\text{To simplify the presentation, we use throughout the paper } \{u_i^1, u_i^2\} \text{ to denote the set of } n \text{ unordered pairs } \{u_1^1, u_1^2\}, \{u_2^1, u_2^2\}, \ldots, \{u_n^1, u_n^2\}.\]
two. However, note that, by exchanging the lines \(u_1^1\) and \(u_2^2\) in \(R\), the resulting permutation representation \(R'\) is acyclic with respect to \(\{u_i^1, u_i^2\}_{i=1}^{n}\), and thus \(P\) is acyclic with respect to \(\{u_i^1, u_i^2\}_{i=1}^{2}\).

![Figure 1: (a) A permutation graph \(P\), (b) a permutation representation \(R\) of \(P\), (c) the transitive orientation \(\Phi_R\) of \(P\), and (d) the corresponding simple directed graph \(F_R\).](image)

**Definition 2** Let \(G\) be a trapezoid graph with \(n\) vertices and \(R\) be a trapezoid representation of \(G\). Let \(P\) be the permutation graph with \(2n\) vertices corresponding to the left and right lines of the trapezoids in \(R\), \(R_P\) be the permutation representation of \(P\) induced by \(R\), and \(\{u_i^1, u_i^2\}\) be the vertices of \(P\) that correspond to the same vertex \(u_i\) of \(G\), \(i = 1, 2, \ldots, n\). Then,

1. \(R\) is an acyclic trapezoid representation, if \(R_P\) is an acyclic permutation representation with respect to \(\{u_i^1, u_i^2\}_{i=1}^{n}\).
2. \(G\) is an acyclic trapezoid graph, if it has an acyclic representation \(R\).

The following lemma follows easily from Definitions 1 and 2.

**Lemma 1** Any parallelogram graph is an acyclic trapezoid graph.

**Proof.** Let \(G\) be a parallelogram graph with \(n\) vertices \(\{u_1, u_2, \ldots, u_n\}\) and \(R\) be a parallelogram representation of \(G\). That is, \(R\) is a trapezoid representation of \(G\), such that the left and right lines \(l(T_{u_i})\) and \(r(T_{u_i})\) of the trapezoid \(T_{u_i}\), \(i = 1, 2, \ldots, n\), are parallel in \(R\), i.e. \(\theta_R(l(T_{u_i})) = \theta_R(r(T_{u_i}))\). Let \(P\) be the permutation graph with \(2n\) vertices \(\{u_1^1, u_1^2, u_2^1, u_2^2, \ldots, u_n^1, u_n^2\}\) corresponding to the left and right lines of the trapezoids of \(G\) in \(R\), i.e. the vertices \(u_i^1\) and \(u_i^2\) correspond to \(l(T_{u_i})\) and \(r(T_{u_i})\), \(i = 1, 2, \ldots, n\), respectively. Let \(R_P\) be the permutation representation of \(P\) induced by \(R\), and \(\Phi_{R_P}\) be the corresponding transitive orientation of the permutation graph \(P\). Recall that, for two intersecting lines \(a, b\) in \(R_P\), it holds \(ab \in \Phi_{R_P}\) whenever \(\theta(a) < \theta(b)\). It follows that for any \(i = 1, 2, \ldots, n\), the pair \(\{u_i^1, u_i^2\}\) of vertices in \(P\) has incoming edges from (resp. outgoing edges to) vertices of other pairs \(\{u_j^1, u_j^2\}\) in \(\Phi_{R_P}\), which have smaller (resp. greater) angle with the line \(L_2\) in \(R_P\). Thus, the simple directed graph \(F_{R_P}\) defined in Definition 1 has no directed cycles, and therefore \(R_P\) is an acyclic permutation representation with respect to \(\{u_i^1, u_i^2\}_{i=1}^{n}\), i.e. \(R\) is an acyclic trapezoid representation of \(G\) by Definition 2.

**2.2 Structural properties of trapezoid graphs**

In the following, we state some definitions concerning an arbitrary simple undirected graph \(G = (V, E)\), which are useful for our analysis. Although these definitions apply to any graph, we will use them only for trapezoid graphs. Similar definitions, for the restricted case where the graph \(G\) is connected, were studied in [6]. For \(u \in V\) and \(U \subseteq V\), \(N(u) = \{v \in V \mid uv \in E\}\) is the set of adjacent vertices of \(u\) in \(G\), \(N[u] = N(u) \cup \{u\}\), and \(N(U) = \bigcup_{u \in U} N(u) \setminus U\). If \(N(U) \subseteq N(W)\) for two vertex subsets \(U\) and \(W\), then \(U\) is said to be neighborhood dominated by \(W\). Clearly, the relationship of neighborhood domination is transitive.

5
Let $C_1, C_2, \ldots, C_\omega$, $\omega \geq 1$, be the connected components of $G \setminus N[u]$ and $V_i = V(C_i)$, $i = 1, 2, \ldots, \omega$. For simplicity of the presentation, we will identify in the sequel the component $C_i$ and its vertex set $V_i$, $i = 1, 2, \ldots, \omega$. For $i = 1, 2, \ldots, \omega$, the neighborhood domination closure of $V_i$ with respect to $u$ is the set $D_u(V_i) = \{ V_p \mid N(V_p) \subseteq N(V_i) \}$, $p = 1, 2, \ldots, \omega$ of connected components of $G \setminus N[u]$. A component $V_i$ is called a master component of $u$ if $|D_u(V_i)| \geq |D_u(V_j)|$ for all $j = 1, 2, \ldots, \omega$. The closure complement of the neighborhood domination closure $D_u(V_i)$ is the set $D_u^*(V_i) = \{ V_1, V_2, \ldots, V_\omega \} \setminus D_u(V_i)$. Finally, for a subset $S \subseteq \{ V_1, V_2, \ldots, V_\omega \}$, a component $V_j \in S$ is called maximal if there is no component $V_k \in S$ such that $N(V_j) \subseteq N(V_k)$.

Intuitively, if $G$ is a trapezoid graph and $R$ is a trapezoid representation of $G$, one can think of a master component $V_i$ of $u$ as the first connected component of $G \setminus N[u]$ to the right, or to the left of $T_u$ in $R$. For example, consider the trapezoid graph $G$ with vertex set $\{ u, u_1, u_2, u_3, v_1, v_2, v_3, v_4 \}$, which is given by the trapezoid representation $R$ of Figure 2. The connected components of $G \setminus N[u] = \{ v_1, v_2, v_3, v_4 \}$ are $V_1 = \{ v_1 \}$, $V_2 = \{ v_2 \}$, $V_3 = \{ v_3 \}$, and $V_4 = \{ v_4 \}$. Then, $N(V_1) = \{ u_1 \}$, $N(V_2) = \{ u_1, u_3 \}$, $N(V_3) = \{ u_2, u_3 \}$, and $N(V_4) = \{ u_3 \}$. Hence, $D_u(V_1) = \{ V_1 \}$, $D_u(V_2) = \{ V_1, V_2, V_3 \}$, $D_u(V_3) = \{ V_3, V_4 \}$, and $D_u(V_4) = \{ V_4 \}$; thus $V_2$ is the only master component of $u$. Furthermore, $D_u^*(V_1) = \{ V_2, V_3, V_4 \}$, $D_u^*(V_2) = \{ V_3 \}$, $D_u^*(V_3) = \{ V_1, V_2 \}$, and $D_u^*(V_4) = \{ V_1, V_2, V_3 \}$.

![Figure 2: A trapezoid representation $R$ of a trapezoid graph $G$.](image)

**Lemma 2** Let $G$ be a simple graph, $u$ be a vertex of $G$, and let $V_1, V_2, \ldots, V_\omega$, $\omega \geq 1$, be the connected components of $G \setminus N[u]$. If $V_i$ is a master component of $u$, such that $D_u^*(V_i) \neq \emptyset$, then $D_u^*(V_j) \neq \emptyset$ for every component $V_j$ of $G \setminus N[u]$.

**Proof.** Since $V_i$ is a master component, and since $D_u^*(V_i) \neq \emptyset$, it follows that $|D_u(V_j)| \leq |D_u(V_i)| < \omega$ for every connected component $V_j \in \{ V_1, V_2, \ldots, V_\omega \}$. Therefore, $|D_u(V_j)| < \omega$, and thus, $D_u^*(V_j) \neq \emptyset$ as well.

In the following we investigate several properties of trapezoid graphs, in order to derive the vertex-splitting algorithm Split-$U$ in Section 2.3.

**Remark 1** Similar properties of trapezoid graphs have been studied in [6], leading to another vertex-splitting algorithm, called Split-All. However, the algorithm proposed in [6] is incorrect, since it is based on an incorrect property\(^1\), as was also verified by [7]. In the sequel of this section, we present new definitions and properties. In the cases where a similarity arises with those of [6], we refer to it specifically.

The next lemma, which has been stated in Observation 3.1(4) in [6] (without a proof), will be used in our analysis below. For the sake of completeness, we present in the following its proof.

\(^1\)In Observation 3.1(5) of [6], it is claimed that for an arbitrary trapezoid representation $R$ of a connected trapezoid graph $G$, where $V_i$ is a master component of $u$ such that $D_u^*(V_i) \neq \emptyset$ and $R(V_i) \ll_R T_u$, it holds $R(D_u(V_i)) \ll_R T_u \ll_R R(D_u^*(V_i))$. However, the first part of the latter inequality is not true. For instance, in the trapezoid graph $G$ of Figure 2, $V_2 = \{ v_2 \}$ is a master component of $u$, where $D_u^*(V_2) = \{ V_3 \} = \{ \{ v_3 \} \} \neq \emptyset$ and $R(V_2) \ll_R T_u$. However, $V_4 = \{ v_4 \} \in D_u(V_2)$ and $T_u \ll_R T_{v_4}$, and thus, $R(D_u(V_4)) \ll_R T_u$. 

6
Lemma 3 Let $R$ be a trapezoid representation of a trapezoid graph $G$, and $V_i$ be a master component of a vertex $u$ of $G$ such that $R(V_i) \ll_R T_u$. Then, $T_u \ll_R R(V_j)$ for every component $V_j \in D_u^*(V_i)$.

Proof. Suppose otherwise that $R(V_j) \ll_R T_u$, for some $V_j \in D_u^*(V_i)$. Consider first the case where $R(V_j) \ll_R R(V_i) \ll_R T_u$. Then, since $V_i$ lies between $V_j$ and $T_u$ in $R$, all trapezoids that intersect $T_u$ and $V_j$, must also intersect $V_i$. Thus, $N(V_j) \subseteq N(V_i)$, i.e. $V_j \in D_u(V_i)$, which is a contradiction, since $V_j \in D_u^*(V_i)$. Consider now the case where $R(V_i) \ll_R R(V_j) \ll_R T_u$. Then, we obtain similarly that $N(V_i) \subseteq N(V_j)$, and thus, $D_u(V_i) \subseteq D_u(V_j)$. Since $V_j \in D_u(V_j) \setminus D_u(V_i)$, it follows that $|D_u(V_i)| < |D_u(V_j)|$. This is a contradiction to the assumption that $V_i$ is a master component of $u$. Thus, $T_u \ll_R R(V_j)$ for every $V_j \in D_u^*(V_i)$. □

In the following two definitions, we partition the neighbors $N(u)$ of a vertex $u$ in a trapezoid graph $G$ into four possibly empty sets. In the first definition, these sets depend on the graph $G$ itself and on two particular connected components $V_i$ and $V_j$ of $G \setminus N[u]$, while in the second one, they depend on a particular trapezoid representation $R$ of $G$.

Definition 3 Let $G$ be a trapezoid graph, and $u$ be a vertex of $G$. Let $V_i$ be a master component of $u$, such that $D_u^*(V_i) \neq \emptyset$, and $V_j$ be a maximal component of $D_u^*(V_i)$. Then, the vertices of $N(u)$ are partitioned into four possibly empty sets:

1. $N_0(u, V_i, V_j)$: vertices not adjacent to either $V_i$ or $V_j$,
2. $N_1(u, V_i, V_j)$: vertices adjacent to $V_i$ but not to $V_j$,
3. $N_2(u, V_i, V_j)$: vertices adjacent to $V_j$ but not to $V_i$,
4. $N_1(u, V_i, V_j)$: vertices adjacent to both $V_i$ and $V_j$.

Definition 4 Let $G$ be a trapezoid graph, $R$ be a representation of $G$, and $u$ be a vertex of $G$. Denote by $D_1(u, R)$ and $D_2(u, R)$ the sets of trapezoids of $R$ that lie completely to the left and to the right of $T_u$ in $R$, respectively. Then, the vertices of $N(u)$ are partitioned into four possibly empty sets:

1. $N_0(u, R)$: vertices not adjacent to either $D_1(u, R)$ or $D_2(u, R)$,
2. $N_1(u, R)$: vertices adjacent to $D_1(u, R)$ but not to $D_2(u, R)$,
3. $N_2(u, R)$: vertices adjacent to $D_2(u, R)$ but not to $D_1(u, R)$,
4. $N_1(u, R)$: vertices adjacent to both $D_1(u, R)$ and $D_2(u, R)$.

The following lemma connects the last two definitions; in particular, it states that, if $R(V_i) \ll_R T_u$, then the partitions of the set $N(u)$ defined in Definitions 3 and 4 coincide. This Lemma will enable us to define in the sequel a partition of the set $N(u)$, independently of any trapezoid representation $R$ of $G$, and regardless of any particular connected components $V_i$ and $V_j$ of $G \setminus N[u]$, cf. Definition 6.

Lemma 4 Let $G$ be a trapezoid graph, $R$ be a representation of $G$, and $u$ be a vertex of $G$. Let $V_i$ be a master component of $u$, such that $D_u^*(V_i) \neq \emptyset$, and let $V_j$ be a maximal component of $D_u^*(V_i)$. If $R(V_i) \ll_R T_u$, then $N_X(u, V_i, V_j) = N_X(u, R)$ for every $X \in \{0, 1, 2, 12\}$.

Proof. Since $D_u^*(V_i) \neq \emptyset$ and $R(V_i) \ll_R T_u$, it follows by Lemma 3 that $T_u \ll_R R(V_j)$, i.e. $V_j \in D_2(u, R)$. Suppose that a component $V_l \neq V_j$ is the leftmost one of $D_2(u, R)$ in $R$, i.e. $T_u \ll_R R(V_l) \ll_R R(V_j)$. Since $V_l$ lies between $T_u$ and $V_j$ in $R$, all trapezoids that intersect $T_u$ and $V_j$, must also intersect $V_l$, and thus, $N(V_j) \subseteq N(V_l)$. It follows that $V_l \in D_u^*(V_i)$,
This proves the lemma.

\[ \text{i.e. } V_i \notin D_u(V_i), \text{ since otherwise } V_j \in D_u(V_i), \text{ which is a contradiction. Furthermore, since } V_j \text{ is a maximal component of } D_u^*(V_i), \text{ and since } N(V_j) \subseteq N(V_i), \text{ it follows that } N(V_j) = N(V_i), \text{ i.e. } N_X(u, V_i, V_j) = N_X(u, V_i, V_j) \text{ for every } X \in \{0, 1, 2, 12\}. \]

Suppose that a component \( V_k \neq V_i \) is the rightmost one of \( D_1(u, R) \) in \( R \), i.e. \( R(V_i) \ll_R R(V_k) \ll_R T_u \). Then, \( V_k \in D_u(V_i) \), since otherwise \( T_u \ll R(V_k) \) by Lemma 3, which is a contradiction. Thus, \( N(V_k) \subseteq N(V_i) \). Furthermore, since \( V_k \) lies between \( V_j \) and \( T_u \) in \( R \), all trapezoids that intersect \( T_u \) and \( V_j \), must also intersect \( V_k \), and thus, \( N(V_i) \subseteq N(V_k) \). Therefore, \( N(V_i) = N(V_k) \), i.e. \( N_X(u, V_i, V_j) = N_X(u, V_k, V_i) \) for every \( X \in \{0, 1, 2, 12\} \), and thus, \( N_X(u, V_i, V_j) = N_X(u, R) \) for every \( X \in \{0, 1, 2, 12\} \).

Consider now a vertex \( v \in N(u) \), and recall that \( V_k \) (resp. \( V_i \)) is the rightmost (resp. leftmost) component of \( D_1(u, R) \) (resp. \( D_2(u, R) \)) in \( R \). Thus, if \( T_v \) intersects at least one component of \( D_1(u, R) \) (resp. \( D_2(u, R) \)), then \( T_v \) intersects also with \( V_k \) (resp. \( V_i \)). On the other hand, if \( T_v \) does not intersect any component of \( D_1(u, R) \) (resp. \( D_2(u, R) \)), then \( T_v \) clearly does not intersect \( V_k \) (resp. \( V_i \)), since \( V_k \subseteq D_1(u, R) \) (resp. \( V_j \subseteq D_2(u, R) \)). It follows that \( N_X(u, V_k, V_j) = N_X(u, R) \), and thus, \( N_X(u, V_i, V_j) = N_X(u, R) \) for every \( X \in \{0, 1, 2, 12\} \).

This proves the lemma.

Note that, given a trapezoid representation \( R \) of \( G \), we may assume in Lemma 4 without loss of generality that \( R(V_i) \ll_R T_u \), by possibly performing a vertical axis flipping of \( R \). Thus, we can state now the following definition of the sets \( \delta_u \) and \( \delta_u^* \), regardless of the choice the components \( V_i \) and \( V_j \) of \( u \).

**Definition 5** Let \( G \) be a trapezoid graph, \( u \) be a vertex of \( G \), and \( V_i \) be an arbitrarily chosen master component of \( u \). Then, \( \delta_u = V_i \) and

1. if \( D_u^*(V_i) = \emptyset \), then \( \delta_u^* = \emptyset \),
2. if \( D_u^*(V_i) \neq \emptyset \), then \( \delta_u^* = V_j \), for an arbitrarily chosen maximal component \( V_j \in D_u^*(V_i) \).

From now on, whenever we speak about \( \delta_u \) and \( \delta_u^* \), we assume that these arbitrary choices of \( V_i \) and \( V_j \) have been already made. Now, we are ready to define the following partition of the set \( N(u) \), which will be used for the vertex splitting in Algorithm Split-U, cf. Definition 7.

**Definition 6** Let \( G \) be a trapezoid graph and \( u \) be a vertex of \( G \). The vertices of \( N(u) \) are partitioned into four possibly empty sets:

1. \( N_0(u) \): vertices not adjacent to either \( \delta_u \) or \( \delta_u^* \),
2. \( N_1(u) \): vertices adjacent to \( \delta_u \) but not to \( \delta_u^* \),
3. \( N_2(u) \): vertices adjacent to \( \delta_u^* \) but not to \( \delta_u \),
4. \( N_{12}(u) \): vertices adjacent to both \( \delta_u \) and \( \delta_u^* \).

The next corollary follows now from Lemma 4 and Definitions 5 and 6.

**Corollary 1** Let \( G \) be a trapezoid graph, \( R \) be a representation of \( G \), and \( u \) be a vertex of \( G \) with \( \delta_u^* \neq \emptyset \). Let \( V_i \) be the master component of \( u \) that corresponds to \( \delta_u \). If \( R(V_i) \ll_R T_u \), then \( N_X(u) = N_X(u, R) \) for every \( X \in \{0, 1, 2, 12\} \).

In the following, we state two auxiliary lemmas that will be used in the proof of Theorem 1.

**Lemma 5** Let \( G \) be a trapezoid graph and \( u \) be a vertex of \( G \). Then, \( N_2(u) \cup N_{12}(u) = \emptyset \) if and only if \( \delta_u^* = \emptyset \).
Proof. Suppose first that $\delta^*_u = \emptyset$. Then, clearly there exists no vertex $v \in N(u)$ adjacent to $\delta^*_u$, and thus, $N_2(u) \cup N_{12}(u) = \emptyset$. Conversely, suppose that $N_2(u) \cup N_{12}(u) = \emptyset$, and assume that $\delta^*_u \neq \emptyset$. Let $V_i = \delta_u$ and $\delta^*_u = V_j$, where $V_i$ is a master component of $u$ and $V_j$ is a maximal component of $D^*_u(V_i)$. If $N(V_j) = \emptyset$, then clearly $N(V_j) \subseteq N(V_i)$, and thus, $V_j \in D_u(V_i)$, which is a contradiction. Thus, $N(V_j) \neq \emptyset$, i.e. some vertices of $N(u)$ are adjacent to some vertices of $V_j$. Since $\delta^*_u = V_j$, it follows by Definition 6 that $N_2(u) \cup N_{12}(u) \neq \emptyset$, which is a contradiction. Thus, $\delta^*_u = \emptyset$. \hfill \Box

Lemma 6 Let $G$ be a trapezoid graph and $u$ be a vertex of $G$. If $\delta^*_u \neq \emptyset$, then $N_1(u) \cup N_{12}(u) \neq \emptyset$.

Proof. Suppose that $\delta^*_u \neq \emptyset$. Let $V_i$ be the master component that corresponds to $\delta_u$, and $V_j$ be the maximal component of $D^*_u(V_i)$ that corresponds to $\delta^*_u$. Assume that $N_1(u) \cup N_{12}(u) = \emptyset$, i.e. no neighbor of $u$ is adjacent to any vertex $v \in V_i$. It follows that $N(V_i) = \emptyset$. On the other hand, since $\delta^*_u \neq \emptyset$, we obtain by Lemma 5 that $N_2(u) \cup N_{12}(u) \neq \emptyset$. That is, some neighbors of $u$ are adjacent to some vertices of $V_j$, i.e. $N(V_j) \neq \emptyset$. Therefore, $N(V_i) = \emptyset \subset N(V_j)$, and thus, $D_u(V_i) \subset D_u(V_j)$, i.e. $|D_u(V_i)| < |D_u(V_j)|$. This is a contradiction, since $V_i$ is a master component of $u$. Thus, $N_1(u) \cup N_{12}(u) \neq \emptyset$. \hfill \Box

2.3 A splitting algorithm

We define now the splitting of a vertex $u$ of a trapezoid graph $G$, where $\delta^*_u \neq \emptyset$. Note that this splitting operation does not depend on any trapezoid representation of $G$. Intuitively, if the graph $G$ was given along with a specific trapezoid representation $R$, this would have meant that we replace the trapezoid $T_u$ in $R$ by its two lines $l(T_u)$ and $r(T_u)$.

Definition 7 Let $G$ be a trapezoid graph and $u$ be a vertex of $G$, where $\delta^*_u \neq \emptyset$. The graph $G^\#(u)$ obtained by the vertex splitting of $u$ is defined as follows:

1. $V(G^\#(u)) = V(G) \setminus \{u\} \cup \{u_1, u_2\}$, where $u_1$ and $u_2$ are the two new vertices.

2. $E(G^\#(u)) = E(V(G) \setminus \{u\}) \cup \{u_1x \mid x \in N_1(u)\} \cup \{u_2x \mid x \in N_2(u)\} \cup \{u_1x, u_2x \mid x \in N_{12}(u)\}$.

The vertices $u_1$ and $u_2$ are the derivatives of vertex $u$.

We state now the notion of a standard trapezoid representation with respect to a particular vertex.

Definition 8 Let $G$ be a trapezoid graph and $u$ be a vertex of $G$, where $\delta^*_u \neq \emptyset$. A trapezoid representation $R$ of $G$ is standard with respect to $u$, if the following properties are satisfied:

1. $l(T_u) \ll_R R(N_0(u) \cup N_2(u))$.

2. $R(N_0(u) \cup N_1(u)) \ll_R r(T_u)$.

Now, given a trapezoid graph $G$ and a vertex subset $U = \{u_1, u_2, \ldots, u_k\}$, such that $\delta^*_{u_i} \neq \emptyset$ for every $i = 1, 2, \ldots, k$, Algorithm Split-U returns a graph $G^\#(U)$ by splitting every vertex of $U$ exactly once. At every step, Algorithm Split-U splits a vertex of $U$, and finally, it removes all vertices of the set $V(G) \setminus U$, which have not been split.

Remark 2 As mentioned in Remark 1, a similar algorithm, called Split-All, was presented in [6]. We would like to emphasize here the following four differences between the two algorithms. First, that Split-All gets as input a sibling-free graph $G$ (two vertices $u, v$ of a graph $G$
Algorithm 1 Split-U

Input: A trapezoid graph $G$ and a vertex subset $U = \{u_1, u_2, \ldots, u_k\}$, such that $\delta_{u_i} \neq \emptyset$ for all $i = 1, 2, \ldots, k$

Output: The permutation graph $G^\#(U)$

\[
\begin{align*}
U &\leftarrow V(G) \setminus U; H_0 \leftarrow G \\
\text{for } i = 1 \text{ to } k &\text{ do} \\
H_i &\leftarrow H_{i-1}^\#(u_i) \{H_i \text{ is obtained by the vertex splitting of } u_i \text{ in } H_{i-1}\} \\
G^\#(U) &\leftarrow H_k[V(H_k) \setminus U] \{\text{remove from } H_k \text{ all unsplitted vertices}\} \\
\text{return } & G^\#(U)
\end{align*}
\]

are called siblings, if $N[u] = N[v]$; $G$ is called sibling-free if $G$ has no pair of sibling vertices, while our Algorithm Split-U gets as an input any graph (though, we will use it only for trapezoid graphs), which may contain pairs of sibling vertices. Second, Split-All splits all the vertices of the input graph, while Split-U splits only a subset of them, which satisfy a special property. Third, the order of vertices that are split by Split-All depends on a certain property (inclusion-minimal neighbor set), while Split-U splits the vertices in an arbitrary order. Last, the main difference between these two algorithms is that they perform a different vertex splitting operation at every step, since Definitions 5 and 6 do not comply with the corresponding Definitions 4.1 and 4.2 of [6].

Theorem 1 Let $G$ be a trapezoid graph and $U = \{u_1, u_2, \ldots, u_k\}$ be a vertex subset of $G$, such that $\delta_{u_i} \neq \emptyset$ for every $i = 1, 2, \ldots, k$. Then, the graph $G^\#(U)$ obtained by Algorithm Split-U, is a permutation graph with $2k$ vertices. Furthermore, if $G$ is acyclic, then $G^\#(U)$ is acyclic with respect to $\{u_1^1, u_1^2\}_{i=1}^k$, where $u_1^1$ and $u_1^2$ are the derivatives of $u_i$, $i = 1, 2, \ldots, k$.

Proof. Let $R$ be a trapezoid representation of $G$. In order to prove that the graph $G^\#(U)$ constructed by Algorithm Split-All is a permutation graph, we will construct from $R$ a permutation representation $R^\#(U)$ of $G^\#(U)$. To this end, we will construct sequentially, for every $i = 1, 2, \ldots, k$, a trapezoid trapezoid representation of $H_{i-1}$ with respect to $u_i$, in which all derivatives $u_j^1, u_j^2$, $1 \leq j \leq i - 1$, are represented by trivial trapezoids, i.e. lines.

Let $u = u_1$. If $R$ is not a standard representation with respect to $u$, we construct first from $R$ a trapezoid representation $R'$ of $G$ that satisfies the first condition of Definition 8. Then, we construct from $R'$ a trapezoid representation $R''$ of $G$ that satisfies also the second condition of Definition 8, i.e. $R''$ is a standard trapezoid representation $R'$ of $G$ with respect to $u$.

Let $V_i$ be the master component of $u$ that corresponds to $\delta_u$. By possibly performing a vertical axis flipping of $R$, we may assume without loss of generality that $R(V_i) \ll_R T_u$. Furthermore, the sets $N_0(u)$, $N_1(u)$, $N_2(u)$, and $N_{12}(u)$ coincide by Lemma 1 with the sets $N_0(u, R)$, $N_1(u, R)$, $N_2(u, R)$, and $N_{12}(u, R)$, respectively. Recall that, by Definition 4, $D_1(u, R)$ and $D_2(u, R)$ denote the sets of trapezoids of $R$ that lie completely to the left and to the right of $T_u$ in $R$, respectively.

Let $p_x$ and $q_x$ be the endpoints on $L_1$ and $L_2$, respectively, of the left line $l(T_x)$ of an arbitrary trapezoid $T_x$ in $R$. Suppose that $N_0(u) \cup N_2(u) \neq \emptyset$. Let $p_u$ and $q_u$ be the leftmost endpoints on $L_1$ and $L_2$, respectively, of the trapezoids of $N_0(u) \cup N_2(u)$, and suppose that $p_u < p_x$ and $q_u < q_x$. Note that, possibly, $v = w$. Then, all vertices $x$, for which $T_x$ has an endpoint between $p_x$ and $p_u$ on $L_1$ (resp. between $q_u$ and $q_x$ on $L_2$) are adjacent to $u$. Indeed, suppose otherwise that $T_x \cap T_u = \emptyset$, for such a vertex $x$. Then, $T_x \ll_R T_u$, i.e. $x \in D_1(u, R)$, since $T_x$ has an endpoint to the left of $T_u$ in $R$. Furthermore, since $T_v \cap T_u \neq \emptyset$ (resp. $T_w \cap T_u \neq \emptyset$), it follows that $T_x \cap T_v \neq \emptyset$ (resp. $T_x \cap T_w \neq \emptyset$).
However, since \( x \in D_1(u, R) \), it follows that \( v \in N_1(u, R) \cup N_{12}(u, R) = N_1(u) \cup N_{12}(u) \) (resp. \( w \in N_1(u, R) \cup N_{12}(u, R) = N_1(u) \cup N_{12}(u) \)), which is a contradiction.

Consider now a vertex \( z \in N_1(u) \cup N_{12}(u) \) with \( l(T_z) \ll_R l(T_u) \), where \( p_u < p_z < p_w \). Then, \( q_z < q_w \). Indeed, suppose otherwise that \( q_w < q_z \) (recall that all endpoints are assumed to be distinct). Then, since \( z \in N_1(u) \cup N_{12}(u) \), there exists a vertex \( z \in D_1(u, R) \), i.e. with \( T_z \ll_R T_u \), such that \( T_z \cap T_x \neq \emptyset \). Since \( v, w \in N_0(u) \cup N_2(v) \), it follows that \( T_v \cap T_z = \emptyset \) and \( T_w \cap T_z = \emptyset \), and thus, \( T_x \ll_R T_v \) and \( T_x \ll_R T_w \). Therefore, since \( p_w < p_z \) and \( q_w < q_z \), we obtain that \( T_x \ll_R T_z \), and thus, \( T_z \cap T_x = \emptyset \), which is a contradiction. It follows that \( q_z < q_w \). Moreover, \( z \) is adjacent to all vertices \( x \) in \( G \), whose trapezoid \( T_x \) has an endpoint on \( L_1 \) between \( p_v \) and \( p_z \), including \( p_w \). Indeed, otherwise, \( T_x \ll_R T_z \), and thus, \( T_z \ll_R T_w \), since \( l(T_z) \ll_R l(T_u) \). This is however a contradiction, since \( x \in N(u) \), as we have proved above. Similarly, if \( q_w < q_z < q_u \), then \( p_z < p_v \) and \( z \) is adjacent to all vertices \( x \) in \( G \), whose trapezoid \( T_x \) has an endpoint on \( L_2 \) between \( q_w \) and \( q_z \), including \( q_u \).

We construct now from \( R \) a new trapezoid representation \( R' \) of \( G \) as follows. First, for all vertices \( z \in N_1(u) \cup N_{12}(u) \) with \( l(T_z) \ll_R l(T_u) \), for which \( p_v < p_z < p_u \) (and thus \( q_z < q_w \)), we move the endpoint \( p_z \) of \( l(T_z) \) directly before \( p_v \) on \( L_1 \). In the sequel, for all vertices \( z' \in N_1(u) \cup N_{12}(u) \) with \( l(T_z') \ll_R l(T_u) \), for which \( q_w < q_z' < q_u \) (and thus \( p_z < p_v \)), we move the endpoint \( q_z' \) of \( l(T_z') \) directly before \( q_w \) on \( L_2 \). During the movement of all these lines \( l(T_z) \) (resp. \( l(T_z') \)), we keep the same relative positions of their endpoints \( p_z \) on \( L_1 \) (resp. \( q_z' \) on \( L_2 \)) as in \( R \), and thus we introduce no new line intersection among the lines of the trapezoids of \( G \). Since all these vertices \( z \) (resp. \( z' \)) are adjacent to all vertices \( x \) of \( G \), whose trapezoid \( T_x \) has an endpoint on \( L_1 \) (resp. \( L_2 \)) between \( p_v \) and \( p_z \), including \( p_u \) (resp. between \( q_w \) and \( q_z \)), including \( q_u \), these movements do not remove any adjacency from, and do not add any new adjacency to \( G \).

Finally, we move both endpoints \( p_u \) and \( q_u \) of \( l(T_u) \) directly before \( p_z \) and \( q_w \) on \( L_1 \) and \( L_2 \), respectively. Since \( u \) is adjacent to all vertices \( x \), for which \( T_x \) has an endpoint between \( p_v \) and \( p_u \) on \( L_1 \), or between \( q_w \) and \( q_u \) on \( L_2 \) in \( R \), the resulting representation \( R' \) is a trapezoid representation of \( G \), in which the first condition of Definition 8 is satisfied. Since we moved all lines \( l(T_z) \) and \( l(T_z') \) to the left of \( T_u \) and \( T_w \), \( R' \) has no additional line intersections than \( R \). Moreover, note that for any line intersection of two lines \( a \) and \( b \) in \( R' \), the relative position of the endpoints of \( a \) and \( b \) on \( L_1 \) and \( L_2 \) remains the same as in \( R \). In the case where \( p_u > p_v \) (resp. \( q_w > q_u \)) we replace in the above construction \( p_v \) by \( p_u \) (resp. \( q_w \) by \( q_u \)), while in the case where \( N_0(u) \cup N_2(u) = \emptyset \), we define \( R' = R \). An example of the construction of \( R' \) is given in Figure 3. In this example, \( v \in N_0(u) \), \( w \in N_2(u) \), \( z_1, z_1' \in N_1(u) \) and \( z_2 \in N_1(u) \).

If \( R' \) is not a standard trapezoid representation with respect to \( u \), then we move \( r(T_u) \) to the right (similarly to the above), obtaining thus a trapezoid representation \( R'' \) of \( G \), in which the second condition of Definition 8 is satisfied. Since during the construction of \( R'' \) from \( R' \) only the line \( r(T_u) \), and other lines that lie completely to the right of \( r(T_u) \), are moved to the right, the first condition of Definition 8 is satisfied for \( R'' \) as well. Thus, \( R'' \) is a standard representation of \( G \) with respect to \( u \). Similarly to \( R' \), \( R'' \) has no additional line intersections than \( R \). Moreover, for any line intersection of two lines \( a \) and \( b \) in \( R'' \), the relative position of the endpoints of \( a \) and \( b \) on \( L_1 \) and \( L_2 \) remains the same as in \( R \).

Since \( R'' \) is standard with respect to \( u \), the left line \( l(T_u) \) of \( T_u \) in \( R'' \) intersects exactly with those trapezoids \( T_z \), for which \( z \in N_1(u) \cup N_{12}(u) \). On the other hand, the right line \( r(T_u) \) of \( T_u \) in \( R'' \) intersects exactly with those trapezoids \( T_z \), for which \( z \in N_2(u) \cup N_{12}(u) \). Thus, if we replace in \( R'' \) the trapezoid \( T_u \) by the two trivial trapezoids (lines) \( l(T_u) \) and \( r(T_u) \), we obtain a trapezoid representation \( R^\#(u) \) of the graph \( G^\#(u) \) defined in Definition 7.

Consider now a vertex \( v \in \{ u_2, u_3, \ldots, u_k \} \). Due to the assumption, \( \delta'_v \neq \emptyset \) in \( G \), before the vertex splitting of \( u \), and thus, \( N_2(v) \cup N_{12}(v) \neq \emptyset \) and \( N_1(v) \cup N_{12}(v) \neq \emptyset \) in \( G \) by Lemmas 5 and 6. We will prove that \( \delta'_v \neq \emptyset \) in the trapezoid graph \( G^\#(u) \) as well, after the
vertex splitting of \( u \). Due to Lemma 5, it suffices to show that \( N_2(v) \cup N_{12}(v) \neq \emptyset \) in \( G^\#(u) \). Let \( V_i \) be the master component of \( v \) in \( G \) that corresponds to \( \delta_v \), before the vertex splitting of \( u \). We may assume without loss of generality that \( R''(V_i) \ll R'' T_v \), by possibly performing a vertical axis flipping of \( R'' \). By Lemma 1, \( N_1(v) \cup N_{12}(v) = N_1(v, R'') \cup N_{12}(v, R'') \) and \( N_2(v) \cup N_{12}(v) = N_2(v, R'') \cup N_{12}(v, R'') \), i.e. these are the sets of neighbors of \( v \) in \( G \), whose trapezoids intersect with the trapezoids of \( D_1(v, R'') \) and \( D_2(v, R'') \) in \( R'' \), respectively. Since \( N_1(v, R'') \cup N_{12}(v, R'') \neq \emptyset \) and \( N_2(v, R'') \cup N_{12}(v, R'') \neq \emptyset \) in \( G \), and since \( R^\#(u) \) is obtained from \( R'' \) by replacing the trapezoid \( T_u \) with the lines \( l(T_u) \) and \( r(T_u) \), it follows easily that \( N_1(v, R^\#(u)) \cup N_{12}(v, R^\#(u)) \neq \emptyset \) and \( N_2(v, R^\#(u)) \cup N_{12}(v, R^\#(u)) \neq \emptyset \) as well. Let \( V_k \) be the master component of \( v \) in \( G^\#(u) \) that corresponds to \( \delta_v \), after the vertex splitting of \( u \). If \( V_k \) lies to the left (resp. right) of \( T_v \) in \( R^\#(u) \), then \( N_2(v) \cup N_{12}(v) \) in \( G^\#(u) \) equals to \( N_2(v, R^\#(u)) \cup N_{12}(v, R^\#(u)) \) (resp. to \( N_1(v, R^\#(u)) \cup N_{12}(v, R^\#(u)) \), by performing a vertical axis flipping of \( R^\#(u) \)). Therefore, \( N_2(v) \cup N_{12}(v) \neq \emptyset \), and thus, \( \delta_v \neq \emptyset \) in \( G^\#(u) \), after the vertex splitting of \( u \).

Applying iteratively the above construction for \( u = u_i \), \( i = 2, 3, \ldots, k \), i.e. by splitting sequentially all vertices of \( U \) exactly once, we obtain after \( k \) vertex splittings, and after removing from the resulting graph the vertices of \( \overline{U} = V(G) \setminus U \), a trapezoid representation \( R^\#(U) \) of the graph \( G^\#(U) \) returned by Algorithm Split-U. Since every trapezoid \( T_u \), \( u \in U \), has been replaced by two trivial trapezoids, i.e. lines, in \( R^\#(U) \), it follows that \( G^\#(U) \) is a permutation graph with \( 2k \) vertices, and \( R^\#(U) \) is a permutation representation of \( G^\#(U) \).

Finally, suppose that \( R \) is an acyclic trapezoid representation of \( G \). According to Definition 2, let \( P \) be the permutation graph with \( 2n \) vertices corresponding to the left and right lines of the trapezoids in \( R \), \( R_P \) be the permutation representation of \( P \) induced by \( R \), and \( \{u_1^1, u_2^1\} \) be the vertices of \( P \) that correspond to the same vertex \( u_i \) of \( G \), \( i = 1, 2, \ldots, n \). Since \( R \) is an acyclic trapezoid representation of \( G \), it follows by Definition 2 that \( R_P \) is an acyclic permutation representation with respect to \( \{u_1^1, u_2^1\}_{i=1}^n \). That is, the simple directed graph \( F_{R_P} \), obtained (according to Definition 1) by merging \( u_1^1 \) and \( u_2^1 \) in \( P \) into a single vertex \( u_i \), for every \( i = 1, 2, \ldots, n \), has no directed cycle.

Since, during the construction of \( R^\#(U) \), the trapezoid representation obtained after every vertex splitting has no additional line intersections than the previous one, it follows
that \( R^\#(U) \) has no additional line intersections than \( R \). Moreover, for any line intersection of two lines \( a \) and \( b \) in \( R^\#(U) \), the relative position of the endpoints of \( a \) and \( b \) on \( L_1 \) and \( L_2 \) remains the same as in \( R \). Thus, the simple directed graph \( F_{R^\#(U)} \) obtained (according to Definition 1) by merging \( u^1_i \) and \( u^2_i \) in \( G^\#(U) \) into a single vertex \( u_i \), for every \( i = 1, 2, \ldots, k \), is a subgraph of \( F_{R_P} \). Therefore, since \( F_{R_P} \) has no directed cycle, \( F_{R^\#(U)} \) has no directed cycle as well, i.e. \( G^\#(U) \) is an acyclic permutation graph with respect to \( \{u^1_i, u^2_i\}_{i=1}^k \). This completes the proof of the theorem. ■

3 The recognition of bounded tolerance graphs

In this section we provide a reduction from the monotone-Not-All-Equal-3-SAT (monotone-NAE-3-SAT) problem to the problem of recognizing whether a given graph is a bounded tolerance graph. A boolean formula \( \phi \) is called monotone if no variable in \( \phi \) is negated. Given a monotone boolean formula \( \phi \) in conjunctive normal form with three literals in each clause (3-CNF), \( \phi \) is NAESatisfiable if there is a truth assignment of \( \phi \), such that every clause contains at least one true literal and at least one false one. The problem of deciding whether a given monotone 3-CNF formula \( \phi \) is NAE-satisfiable is known to be NP-complete (see [29] for the NP-completeness of NAE-3-SAT\(^3\)). We can assume without loss of generality that each clause has three distinct literals, i.e. variables. Given a monotone 3-CNF formula \( \phi \), we construct in polynomial time a trapezoid graph \( H_\phi \), such that \( H_\phi \) is a bounded tolerance graph if and only if \( \phi \) is NAE-satisfiable. To this end, we construct first a permutation graph \( P_\phi \) and a trapezoid graph \( G_\phi \).

3.1 The permutation graph \( P_\phi \)

Consider a monotone 3-CNF formula \( \phi = \alpha_1 \land \alpha_2 \land \ldots \land \alpha_k \) with \( k \) clauses and \( n \) boolean variables \( x_1, x_2, \ldots, x_n \), such that \( \alpha_i = (x_{r_{i,1}} \lor x_{r_{i,2}} \lor x_{r_{i,3}}) \) for \( i = 1, 2, \ldots, k \), where \( 1 \leq r_{i,1} < r_{i,2} < r_{i,3} \leq n \). We construct the permutation graph \( P_\phi \), along with a permutation representation \( R_P \) of \( P_\phi \), as follows. Let \( L_1 \) and \( L_2 \) be two parallel lines and let \( \theta(\ell) \) denote the angle of the line \( \ell \) with \( L_2 \) in \( R_P \). For every clause \( \alpha_i, i = 1, 2, \ldots, k \), we correspond to each of the literal, i.e. variables, \( x_{r_{i,1}}, x_{r_{i,2}}, \) and \( x_{r_{i,3}} \) a pair of intersecting lines with endpoints on \( L_1 \) and \( L_2 \). Namely, we correspond to the variable \( x_{r_{i,1}} \) the pair \( \{a_i, c_i\} \), to \( x_{r_{i,2}} \) the pair \( \{e_i, b_i\} \) and to \( x_{r_{i,3}} \) the pair \( \{d_i, f_i\} \), respectively, such that \( \theta(a_i) > \theta(c_i) \), \( \theta(e_i) > \theta(b_i) \), \( \theta(d_i) > \theta(f_i) \), and such that the lines \( a_i, c_i \) lie completely to the left of \( e_i, b_i \) in \( R_P \), and \( e_i, b_i \) lie completely to the left of \( d_i, f_i \) in \( R_P \), as it is illustrated in Figure 4. Denote the lines that correspond to the variable \( x_{r_{i,j}}, j = 1, 2, 3, \) by \( \ell_{i,j}^1 \) and \( \ell_{i,j}^2 \), respectively, such that \( \theta(\ell_{i,j}^1) > \theta(\ell_{i,j}^2) \). That is, \( (\ell_{i,1}^1, \ell_{i,1}^2) = (a_i, c_i), (\ell_{i,2}^1, \ell_{i,2}^2) = (e_i, b_i), \) and \( (\ell_{i,3}^1, \ell_{i,3}^2) = (d_i, f_i) \). Note that no line of a pair \( \{\ell_{i,j}^1, \ell_{i,j}^2\} \) intersects with a line of another pair \( \{\ell_{i,j'}^1, \ell_{i,j'}^2\} \).

\[
\begin{array}{cccc}
\ell_{i,1}^1 &=& a_i & L_1 \\
\ell_{i,1}^2 &=& c_i & \\
\ell_{i,2}^1 &=& e_i & \\
\ell_{i,2}^2 &=& b_i & \\
\ell_{i,3}^1 &=& d_i & L_2 \\
\ell_{i,3}^2 &=& f_i & \\
\end{array}
\]

Figure 4: The six lines of the permutation graph \( P_\phi \), which correspond to the clause \( \alpha_i = (x_{r_{i,1}} \lor x_{r_{i,2}} \lor x_{r_{i,3}}) \) of the boolean formula \( \phi \).

\(^3\)To reduce NAE-3-SAT to monotone-NAE-3-SAT, replace each variable \( x \) with two variables \( x_0 \) and \( x_1 \) (depending on whether \( x \) appears negated or not), add variables \( x_2, x_3, x_4, \) and add the clauses \( (x_0 \lor x_1 \lor x_2), (x_0 \lor x_1 \lor x_3), (x_0 \lor x_1 \lor x_4), \) and \( (x_2 \lor x_3 \lor x_4) \).
Denote by $S_p$, $p = 1, 2, \ldots, n$, the set of pairs $\{\ell^1_{i,j}, \ell^2_{i,j}\}$ that correspond to the variable $x_p$, i.e. $r_{i,j} = p$. We order the pairs $\{\ell^1_{i,j}, \ell^2_{i,j}\}$ such that any pair of $S_p$, whenever $p_1 < p_2$, while the pairs that belong to the same set $S_p$ are ordered arbitrarily. For two consecutive pairs $\{\ell^1_{i,j}, \ell^2_{i,j}\}$ and $\{\ell^1_{i,j'}, \ell^2_{i,j'}\}$ in $S_p$, where $\{\ell^1_{i,j}, \ell^2_{i,j}\}$ lies to the left of $\{\ell^1_{i,j'}, \ell^2_{i,j'}\}$, we add a pair $(u^x_{i,j'}, v^y_{i,j'})$ of parallel lines that intersect both $\ell^1_{i,j}$ and $\ell^1_{i,j'}$, but no other line. Note that $\theta(\ell^1_{i,j}) > \theta(u^x_{i,j'})$ and $\theta(\ell^2_{i,j}) > \theta(v^y_{i,j'})$, while $\theta(u^x_{i,j'}) = \theta(v^y_{i,j'})$. This completes the construction. Denote the resulting permutation graph by $P_\phi$, and the corresponding permutation representation of $P_\phi$ by $R_P$. Observe that $P_\phi$ has $n$ connected components, which are called blocks, one for each variable $x_1, x_2, \ldots, x_n$.

An example of the construction of $P_\phi$ and $R_P$ from $\phi$ with $k = 3$ clauses and $n = 4$ variables is illustrated in Figure 5. In this figure, the lines $u^x_{i,j}$ and $v^y_{i,j}$ are drawn in bold.

The formula $\phi$ has $3k$ literals, and thus the permutation graph $P_\phi$ has $6k$ lines $\ell^1_{i,j}, \ell^2_{i,j}$ in $R_P$, one pair for each literal. Furthermore, two lines $u^x_{i,j}$ and $v^y_{i,j}$ correspond to each pair of consecutive pairs $\{\ell^1_{i,j}, \ell^2_{i,j}\}$ and $\{\ell^1_{i,j'}, \ell^2_{i,j'}\}$ in $R_P$, except for the case where these pairs of lines belong to different variables, i.e. when $r_{i,j} \neq r_{i,j'}$. Therefore, since $\phi$ has $n$ variables, there are $2(3k - n) = 6k - 2n$ lines $u^x_{i,j}$, $v^y_{i,j}$ in $R_P$. Thus, $R_P$ has in total $12k - 2n$ lines, i.e. $P_\phi$ has $12k - 2n$ vertices. In the example of Figure 5, $k = 3$, $n = 4$, and thus, $P_\phi$ has 28 vertices.

![Figure 5: The permutation representation $R_P$ of the permutation graph $P_\phi$ for $\phi = \alpha_1 \land \alpha_2 \land \alpha_3 = (x_1 \lor x_2 \lor x_3) \land (x_2 \lor x_3 \lor x_4) \land (x_1 \lor x_2 \lor x_4)$](image)

Let $m = 6k - n$, where $2m$ is the number of vertices in $P_\phi$. We group the lines of $R_P$, i.e. the vertices of $P_\phi$, into pairs $\{u^1_i, u^2_i\}_{i=1}^m$, as follows. For every clause $\alpha_i$, $i = 1, 2, \ldots, k$, we group the lines $a_i, b_i, c_i, d_i, e_i, f_i$ into the three pairs $\{a_i, b_i\}$, $\{c_i, d_i\}$, and $\{e_i, f_i\}$. The remaining lines are grouped naturally according to the construction; namely, every two lines $\{u^x_{i,j'}, v^y_{i,j'}\}$ constitute a pair.

**Lemma 7** If the permutation graph $P_\phi$ is acyclic with respect to $\{u^1_i, u^2_i\}_{i=1}^m$ then the formula $\phi$ is NAE-satisfiable.

**Proof.** Suppose that $P_\phi$ is acyclic with respect to $\{u^1_i, u^2_i\}_{i=1}^m$, and let $R_0$ be an acyclic permutation representation of $P_\phi$ with respect to $\{u^1_i, u^2_i\}_{i=1}^m$. Then, in particular, $R_0$ is acyclic with respect to $\{a_i, b_i\}, \{c_i, d_i\}, \{e_i, f_i\}$, for every $i = 1, 2, \ldots, k$. We will construct a truth assignment of the variables $x_1, x_2, \ldots, x_n$ that NAE-satisfies $\phi$, as follows. For every $i = 1, 2, \ldots, k$, we define $x_{r_{i,1}} = 1$ if and only if $\theta(c_i) < \theta(a_i)$ in $R_0$, $x_{r_{i,2}} = 1$ if and only if $\theta(b_i) < \theta(c_i)$ in $R_0$, and $x_{r_{i,3}} = 1$ if and only if $\theta(f_i) < \theta(d_i)$ in $R_0$.

Note that this assignment is consistent; that is, all variables $x_{r_{i,j}}$ that correspond to the same $x_k$ are assigned the same value. Indeed, the existence of the lines $u^x_{i,j'}$, $v^y_{i,j'}$ (cf. the bold lines in Figure 6(a)) forces all pairs of crossing lines $\{\ell^1_{i,j}, \ell^2_{i,j}\}$ in the same block to correspond to either 0 or 1 in the assignment.

Now, we show that in each clause $\alpha_i$, $i = 1, 2, \ldots, k$, there exists at least one true and at least one false variable. For an arbitrary index $i = 1, 2, \ldots, k$, let $P_i$ be the subgraph induced
by the vertices \(a_i, b_i, c_i, d_i, e_i, f_i\) in \(P_\phi\), and \(R_i\) be the permutation representation of \(P_i\), which is induced by \(R_0\). According to Definition 1, we construct the simple directed graph \(F_{R_i}\) by merging into a single vertex each of the pairs \(\{a_i, b_i\}\), \(\{c_i, d_i\}\) and \(\{e_i, f_i\}\) of vertices of \(P_i\). The arc directions of \(F_{R_i}\) are implied by the corresponding directions in \(\Phi_{R_i}\) (or equivalently, in \(\Phi_{R_0}\)). Then, since \(R_0\) is acyclic with respect to \(\{a_i, b_i\} \cup \{c_i, d_i\} \cup \{e_i, f_i\}\), so is \(R_i\). Thus, it follows by Definition 1 that \(F_{R_i}\) has no directed cycle. Therefore, the edges \(c_i a_i, b_i e_i, \text{ and } f_i d_i\) of \(P_\phi\) have such directions in \(\Phi_{R_0}\) that it does not hold simultaneously \(c_i a_i, b_i e_i, f_i d_i \in \Phi_{R_0}\), or \(a_i c_i, e_i b_i, d_i f_i \in \Phi_{R_0}\). That is, it does not hold simultaneously \(\theta(c_i) < \theta(a_i), \theta(b_i) < \theta(e_i)\), and \(\theta(f_i) < \theta(d_i)\), or \(\theta(a_i) < \theta(c_i), \theta(e_i) < \theta(b_i), \text{ and } \theta(d_i) < \theta(f_i)\) in \(R_0\), respectively. Then, by the definition of the above truth assignment, it follows that it does not hold simultaneously \(x_{r_{i,1}} = x_{r_{i,2}} = x_{r_{i,3}} = 1\), or \(x_{r_{i,1}} = x_{r_{i,2}} = x_{r_{i,3}} = 0\), and therefore, the clause \(\alpha_i = (x_{r_{i,1}} \lor x_{r_{i,2}} \lor x_{r_{i,3}})\) is NAE-satisfied. Finally, since this holds for every \(i = 1, 2, \ldots, k\), \(\phi\) is NAE-satisfiable.

For the formula \(\phi\) of Figure 5, an example of an acyclic permutation representation \(R_0\) of \(P_\phi\) with respect to \(\{u_i^1, u_i^2\}_{i=1}^m\), along with the corresponding transitive orientation \(\Phi_{R_0}\) of \(P_\phi\), is illustrated in Figure 6. This transitive orientation corresponds to the NAE-satisfying truth assignment \((x_1, x_2, x_3, x_4) = (1, 1, 0, 0)\) of \(\phi\). Similarly to Figure 5, the lines \(u_i^{1,j}\) and \(u_i^{1,j'}\) are drawn in bold in Figure 6(a). Furthermore, for better visibility, the vertices that correspond to these lines are grouped in shadowed ellipses in Figure 6(b), while the arcs incident to them are drawn dashed.

![Figure 6: The NAE-satisfying truth assignment \((x_1, x_2, x_3, x_4) = (1, 1, 0, 0)\) of the formula \(\phi\) of Figure 5: (a) an acyclic permutation representation \(R_0\) of \(P_\phi\) and (b) the corresponding transitive orientation \(\Phi_{R_0}\) of \(P_\phi\).](image)

3.2 The trapezoid graphs \(G_\phi\) and \(H_\phi\)

Let \(\{u_1, u_2, \ldots, u_m\}\) be the pairs of vertices in the constructed permutation graph \(P_\phi\) and \(R_P\) be its permutation representation. We construct now from \(P_\phi\) the trapezoid graph \(G_\phi\) with \(m\) vertices \(\{u_1, u_2, \ldots, u_m\}\), as follows. We replace in the permutation representation \(R_P\) for
Figure 7: The addition of the six parallelograms $T_{u_1,1}, T_{u_1,2}, \ldots, T_{u_1,6}$ to the trapezoid $T_{u_1}$, $i = 1, 2, \ldots, m$, in the construction of the trapezoid graph $H_\phi$ from $G_\phi$.

every $i = 1, 2, \ldots, m$ the lines $u_1^1$ and $u_1^2$ by the trapezoid $T_{u_1}$, which has $u_1^1$ and $u_1^2$ as its left and right lines, respectively. Let $R_G$ be the resulting trapezoid representation of $G_\phi$.

Finally, we construct from $G_\phi$ the trapezoid graph $H_\phi$ with $7m$ vertices, by adding to every trapezoid $T_{u_i}$, $i = 1, 2, \ldots, m$, six parallelograms $T_{u_1,1}, T_{u_1,2}, \ldots, T_{u_1,6}$ in the trapezoid representation $R_G$, as follows. Let $\varepsilon$ be the smallest distance in $R_G$ between two different endpoints on $L_1$, or on $L_2$. The right (resp. left) line of $T_{u_1,3}$ lies to the right (resp. left) of $u_1^1$, and it is parallel to it at distance $\frac{\varepsilon}{2}$. The right (resp. left) line of $T_{u_1,2}$ lies to the left of $u_1^1$, and it is parallel to it at distance $\frac{\varepsilon}{2}$ (resp. $\frac{3\varepsilon}{2}$). Moreover, the right (resp. left) line of $T_{u_1,3}$ lies to the left of $u_1^1$, and it is parallel to it at distance $\frac{3\varepsilon}{2}$ (resp. $\frac{\varepsilon}{2}$). Similarly, the left (resp. right) line of $T_{u_1,4}$ lies to the left (resp. right) of $u_1^2$, and it is parallel to it at distance $\frac{\varepsilon}{2}$ (resp. $\frac{3\varepsilon}{2}$), as illustrated in Figure 7.

After adding the parallelograms $T_{u_1,1}, T_{u_1,2}, \ldots, T_{u_1,6}$ to a trapezoid $T_{u_1}$, we update the smallest distance $\varepsilon$ between two different endpoints on $L_1$, or on $L_2$ in the resulting representation, and we continue the construction iteratively for all $i = 2, \ldots, m$. Denote by $H_\phi$ the resulting trapezoid graph with $7m$ vertices, and by $R_H$ the corresponding trapezoid representation. Note that in $R_H$, between the endpoints of the parallelograms $T_{u_1,1}, T_{u_1,2},$ and $T_{u_1,3}$ (resp. $T_{u_1,4}, T_{u_1,5},$ and $T_{u_1,6}$) on $L_1$ and $L_2$, there are no other endpoints of $H_\phi$, except those of $u_1^1$ (resp. $u_1^2$), for every $i = 1, 2, \ldots, m$. Furthermore, note that $R_H$ is standard with respect to $u_i$ for every $i = 1, 2, \ldots, m$. The following auxiliary lemma is crucial in the proof of Theorem 2.

**Lemma 8** In the trapezoid graph $H_\phi$, $\delta_i^u \neq \emptyset$ for every $i = 1, 2, \ldots, m$.

**Proof.** Let $i \in \{1, 2, \ldots, m\}$. Recall that, by Definition 4, $D_1(u_i, R_H)$ (resp. $D_2(u_i, R_H)$) denotes the set of trapezoids of $H_\phi$ that lie completely to the left (resp. to the right) of $T_{u_i}$ in $R_H$. In particular, $T_{u,1} \cup T_{u,3} \in D_1(u_i, R_H)$ and $T_{u,5} \cup T_{u,6} \in D_2(u_i, R_H)$. By the construction of $R_H$, it is easy to see that $T_{u,2} \cup T_{u,3}$ (resp. $T_{u,5} \cup T_{u,6}$) is the rightmost (resp. leftmost) connected component of $D_1(u_i, R_H)$ (resp. $D_2(u_i, R_H)$). Thus, $N(V_k) \subseteq N\{u_{i,3}, u_{i,5}\}$ (resp. $N(V_i) \subseteq N\{u_{i,1}, u_{i,6}\}$) for every connected component $V_k$ (resp. $V_i$) of $D_1(u_i, R_H)$ (resp. $D_2(u_i, R_H)$). Let $V_p$ be the master component of $u_i$, such that $D_{u_i} = V_p$. Then, either $V_p = \{u_{i,2}, u_{i,3}\}$, or $V_p = \{u_{i,5}, u_{i,6}\}$. In the case where $V_p = \{u_{i,2}, u_{i,3}\}$, we have $u_{i,4} \in N\{u_{i,5}, u_{i,6}\}$; for every connected component $V_k$ (resp. $V_i$) of $D_1(u_i, R_H)$ (resp. $D_2(u_i, R_H)$). Let $V_p$ be the master component of $u_i$, such that $D_{u_i} = V_p$. Then, either $V_p = \{u_{i,2}, u_{i,3}\}$, or $V_p = \{u_{i,5}, u_{i,6}\}$. In the case where $V_p = \{u_{i,2}, u_{i,3}\}$, we have $u_{i,4} \in N\{u_{i,5}, u_{i,6}\}$; for every connected component $V_k$ (resp. $V_i$) of $D_1(u_i, R_H)$ (resp. $D_2(u_i, R_H)$). Thus, $\delta_i^u \neq \emptyset$. This proves the lemma.

**Theorem 2** The formula $\phi$ is NAE-satisfiable if and only if the trapezoid graph $H_\phi$ is a bounded tolerance graph.
Proof. Since a graph is a bounded tolerance graph if and only if it is a parallelogram graph [2, 21], it suffices to prove that $\phi$ is NAE-satisfiable if and only if the trapezoid graph $H_\phi$ is a parallelogram graph.

(\Rightarrow) Suppose that $H_\phi$ is a parallelogram graph, and let $U = \{u_1, u_2, \ldots, u_m\}$. Then, $H_\phi$ is an acyclic trapezoid graph by Lemma 1. Consider the permutation graph $H_\phi^\#(U)$ with $2m$ vertices, which is obtained by Algorithm Split-$U$ on $H_\phi$. Starting with the trapezoid representation $R_H$ of $H_\phi$, we obtain by the construction of Theorem 1 a permutation representation $R_H^\#(U)$ of $H_\phi^\#(U)$. Note that, since $R_H$ is a standard trapezoid representation of $H_\phi$ with respect to every $u_i$, $i = 1, 2, \ldots, m$, the line $u_i^1$ (resp. $u_i^2$) of $T_{u_i}$ is not moved during the construction of $R_H^\#(U)$ from $R_H$, for every $i = 1, 2, \ldots, m$. Therefore, $H_\phi^\#(U) = P_\phi$. On the other hand, since by Lemma 8 $\delta_{u_i} \neq \emptyset$ for every vertex $u_i \in U$, and since $H_\phi$ is an acyclic trapezoid graph, Theorem 1 implies that $H_\phi^\#(U) = P_\phi$ is an acyclic permutation graph with respect to $\{u_i^1, u_i^2\}_{i=1}^m$. Thus, $\phi$ is NAE-satisfiable by Lemma 7.

(\Leftarrow) Conversely, suppose that $\phi$ has a NAE-satisfying truth assignment $\tau$. We will construct first a permutation representation $R_0$ of $P_\phi$, and then two trapezoid representations $R'_0$ and $R''_0$ of $G_\phi$ and $H_\phi$, respectively, as follows. Similarly to the representation $R_P$, the representation $R_0$ has $n$ blocks, i.e. connected components, one for each variable $x_1, x_2, \ldots, x_n$. $R_0$ is obtained from $R_P$ by performing a horizontal axis flipping of every block, which corresponds to a variable $x_p = 0$ in the truth assignment $\tau$. Every other block, which corresponds to a variable $x_p = 1$ in the assignment $\tau$, remains the same in $R_0$, as in $R_P$. Thus, $\theta(\ell_{ij}^1) > \theta(\ell_{ij}^2)$ if $x_{r_{ij}} = 1$ in $\tau$, and $\theta(\ell_{ij}^1) < \theta(\ell_{ij}^2)$ if $x_{r_{ij}} = 0$ in $\tau$, for every pair $\{\ell_{ij}^1, \ell_{ij}^2\}$ of lines in $R_0$ (which correspond to the literal $x_{r_{ij}}$ of the clause $\alpha_i$ in $\phi$). An example of the construction of this representation $R_0$ of $P_\phi$ for the truth assignment $\tau = (1, 1, 0, 0)$ is illustrated in Figure 6(a).

Since $\tau$ is a NAE-satisfying truth assignment of $\phi$, at least one literal is true and at least one is false in $\tau$ in every clause $\alpha$, $i = 1, 2, \ldots, k$. Thus, there are six possible truth assignments for every clause, namely $(1, 1, 0), (1, 0, 1), (0, 1, 1), (0, 0, 1), (0, 1, 0), (1, 0, 0)$. For the first three ones, we can assign appropriate angles to the lines $a_i, b_i, c_i, d_i, e_i, f_i$ in the representation $R_0$, such that the relative positions of all endpoints in $L_1$ and $L_2$ remain unchanged, and such that $a_i$ is parallel to $b_i$, $c_i$ is parallel to $d_i$, and $e_i$ is parallel to $f_i$, as illustrated in Figure 8. The last three truth assignments of $\alpha_i$ are the complement of the first three ones. Thus, by performing a horizontal axis flipping of the blocks in Figure 8, to which the lines $a_i, b_i, c_i, d_i, e_i, f_i$ belong, it is easy to see that for these assignments, we can also assign appropriate angles to these lines in the representation $R_0$, such that the relative positions of all endpoints in $L_1$ and $L_2$ remain unchanged, and such that $a_i$ is parallel to $b_i$, $c_i$ is parallel to $d_i$, and $e_i$ is parallel to $f_i$.

Recall that for every two consecutive pairs $\{\ell_{ij}^1, \ell_{ij}^2\}$ and $\{\ell_{ij'}^{1'}, \ell_{ij'}^{2'}\}$ of lines in $R_P$ (resp. $R_0$), which belong to the same block, i.e. where $r_{ij} = r_{ij'}$, there are two parallel lines $u_{ij}^{1'}, v_{ij}^{1'}$ that intersect both $\ell_{ij}^1$ and $\ell_{ij'}^{1'}$. Thus, after assigning the appropriate angles to the lines $\{\ell_{ij}^1, \ell_{ij}^2\}$, $i = 1, 2, \ldots, k$, $j = 1, 2, 3$, we can clearly assign the appropriate angles to the lines $u_{ij}^{1'}, v_{ij}^{1'}$, such that the relative positions of all endpoints in $L_1$ and $L_2$ remain unchanged, and such that $u_{ij}^{1'}, v_{ij}^{1'}$ remains parallel to $v_{ij}^{1'}, u_{ij}^{1'}$. Summarizing, the lines $u_i^1$ and $u_i^2$ are parallel in $R_0$, for every $i = 1, 2, \ldots, m$.

We construct now the trapezoid representation $R'_0$ of $G_\phi$ from the permutation representation $R_0$, by replacing for every $i = 1, 2, \ldots, m$ the lines $u_i^1$ and $u_i^2$ by the trapezoid $T_{u_i}$, which has $u_i^1$ and $u_i^2$ as its left and right lines, respectively. Since $R_0$ is obtained by performing horizontal axis flipping of some blocks of $R_P$, and then changing the angles of the lines, while respecting the relative positions of the endpoints, $R'_0$ is indeed another trapezoid
representation of $G_{\phi}$ than $R_G$. Since $u_1^i$ is now parallel to $u_2^i$ for every $i = 1, 2, \ldots, m$, it follows clearly that $R_0'$ is a parallelogram representation, and thus, $G_{\phi}$ is a parallelogram graph.

Finally, we construct the trapezoid representation $R''_0$ of $H_{\phi}$ from $R'_0$, similarly to the construction of $R_H$ from $R_G$. Namely, we add for every trapezoid $T_{u_i}$, $i = 1, 2, \ldots, m$, six parallelograms $T_{u_{i,1}}, T_{u_{i,2}}, \ldots, T_{u_{i,6}}$, resulting in a trapezoid graph with $7m$ vertices. Since in $R''_0$ the parallelograms $T_{u_{i,1}}, T_{u_{i,2}},$ and $T_{u_{i,3}}$ (resp. $T_{u_{i,4}}, T_{u_{i,5}},$ and $T_{u_{i,6}}$) are sufficiently close to the left line $u_1^i$ (resp. right line $u_2^i$) of $T_{u_i}$, $i = 1, 2, \ldots, m$, and since between the endpoints of the parallelograms $T_{u_{i,1}}, T_{u_{i,2}},$ and $T_{u_{i,3}}$ (resp. $T_{u_{i,4}}, T_{u_{i,5}},$ and $T_{u_{i,6}}$) on $L_1$ and $L_2$, there are no other endpoints, it follows that $R''_0$ is indeed another trapezoid representation of $H_{\phi}$ than $R_H$. Finally, since $R'_0$ is a parallelogram representation, and since $T_{u_{i,1}}, T_{u_{i,2}}, \ldots, T_{u_{i,6}},$ $i = 1, 2, \ldots, m$, are all parallelograms, $R''_0$ is also a parallelogram representation, and thus, $H_{\phi}$ is a parallelogram graph.

Therefore, since monotone-NAE-3-SAT is NP-complete, the problem of recognizing bounded tolerance graphs is NP-hard by Theorem 2. Moreover, since the recognition of bounded tolerance graphs lies in NP [17], we can summarize our results as follows.

**Theorem 3** It is NP-complete to decide whether a given graph $G$ is a bounded tolerance graph.

### 4 The recognition of tolerance graphs

In this section we show that the reduction from the monotone-NAE-3-SAT problem to the problem of recognizing bounded tolerance graphs presented in Section 3, can be extended to the problem of recognizing general tolerance graphs. In particular, we prove that a given monotone 3-CNF formula $\phi$ is NAE-satisfiable if and only if the graph $H_{\phi}$ constructed in Section 3.2 is a tolerance graph.

#### 4.1 Structural properties of tolerance graphs

In the following we assume without loss of generality that any tolerance graph has a tolerance representation, in which all tolerances are distinct and no two different intervals share an endpoint [13, 14]. We state now similarly to [14, 15] some definitions and lemmas concerning...
tolerance graphs. In a certain tolerance representation $(I, t)$ of a tolerance graph $G = (V, E)$, a vertex $v$ is called bounded if $t_v \leq |I_v|$; otherwise, $v$ is called unbounded. An unbounded vertex $v$ of $G$ is called inevitable (for a certain tolerance representation), if $v$ is not an isolated vertex, and if setting $t_v = |I_v|$ creates a new edge in the representation, that is, the representation is no longer a tolerance representation of $G$. A tolerance representation of $G$ is called inevitable unbounded, if every unbounded vertex in this representation is inevitable. For an inevitable unbounded vertex $v$ of $G$ (for a certain tolerance representation), a vertex $u$ is called a hovering vertex of $v$, if $uv \notin E$ and $I_v \subseteq I_u$. The next lemma follows easily from the above definitions.

**Lemma 9** There exists a hovering vertex $u$ for every inevitable unbounded vertex $v$ of the tolerance graph $G$ (for a certain tolerance representation).

**Proof.** Since $v$ is an inevitable unbounded vertex, setting $t_v = |I_v|$ creates a new edge in $G$; let $uv$ be such an edge. Then, clearly $I_u \cap I_v \neq \emptyset$. Since initially $uv \notin E$, it follows that $|I_u \cap I_v| < \min\{t_u, t_v\} \leq t_v$. Furthermore, since setting $t_v = |I_v|$ creates a new edge in $G$, we obtain that $\min\{t_u, |I_v|\} \leq |I_u \cap I_v| < t_v$, and thus, $|I_u \cap I_v| = |I_v|$, i.e. $I_v \subseteq I_u$. Therefore, since $uv \notin E$ and $I_v \subseteq I_u$, it follows that $u$ is a hovering vertex of $v$. \qed

**Lemma 10 ([24])** Every tolerance representation can be transformed into an inevitable one in $O(n \log n)$ time.

**Lemma 11** Let $v$ be an inevitable unbounded vertex of a tolerance graph $G$ and $u$ be a hovering vertex of $v$, in a certain tolerance representation of $G$. Then, $N(v) \subseteq N(u)$ in $G$.

**Proof.** Since $v$ is an inevitable unbounded vertex, $N(v) = \emptyset$. Let $w \in N(v)$ be a neighbor of $v$ in $G$. Since $u$ is a hovering vertex of $v$, it follows that $uv \notin E$, and thus, $w \neq u$. Furthermore, since $uw \in E$, and since $v$ is unbounded, we obtain that $\min\{t_v, t_w\} \leq |I_v \cap I_w| \leq |I_v| < t_v$, and thus, $t_w \leq |I_v \cap I_w|$. Then, since $I_v \subseteq I_u$, it follows that $|I_v \cap I_w| \leq |I_u \cap I_w|$, and thus, $t_w \leq |I_u \cap I_w|$, i.e. $w \in N(u)$. Therefore, $N(v) \subseteq N(u)$ in $G$. \qed

### 4.2 The Reduction

Consider now a monotone 3-CNF formula $\phi$ and the trapezoid graph $H_\phi$ constructed from $\phi$ in Section 3.2.

**Lemma 12** In the trapezoid graph $H_\phi$, there are no two vertices $u$ and $v$, such that $uv \notin E(H_\phi)$ and $N(v) \subseteq N(u)$ in $H_\phi$.

**Proof.** The proof is done by investigating all cases for a pair of non-adjacent vertices $u, v$. First, observe that, by the construction of $H_\phi$ from $G_\phi$, we have $N[u_{i,2}] = N[u_{i,3}], N[u_{i,1}] = N[u_{i,2}] \cup \{u_i\}, N[u_{i,5}] = N[u_{i,6}]$, and $N[u_{i,4}] = N[u_{i,5}] \cup \{u_i\}$.

Consider first two vertices $u_i$ and $u_k$ in $H_\phi$, for some $i, k = 1, 2, \ldots, m$ and $i \neq k$. Then, by the construction of $H_\phi$ from $G_\phi$, and since $u_i$ and $u_k$ are non-adjacent, $u_{i,1} \in N(u_i) \setminus N(u_k)$ and $u_{k,1} \in N(u_k) \setminus N(u_i)$. Consider next the vertices $u_i$ and $u_{i,j}$, for some $i, k = 1, 2, \ldots, m$ and $j = 1, 2, \ldots, 6$. If $i = k$, then $j \in \{2, 3, 5, 6\}$, since $u_{i,1,4} \in N(u_i)$. In the case where $j \in \{2, 3\}$, we have $u_{i,4} \in N(u_i) \setminus N(u_{i,j})$ and $u_{k,5-j} \in N(u_{k,j}) \setminus N(u_i)$, while in the case where $j \in \{5, 6\}$, we have $u_{i,1} \in N(u_i) \setminus N(u_{i,j})$ and $u_{k,11-j} \in N(u_{k,j}) \setminus N(u_i)$. Suppose that $i \neq k$. Then, it follows by the construction of $H_\phi$ from $G_\phi$ that $u_{i,1,4} \in N(u_i) \setminus N(u_{k,j})$. Furthermore, if $j \in \{1, 2, 3\}$ (resp. $j \in \{4, 5, 6\}$), then $u_{k,j'} \in N(u_{k,j}) \setminus N(u_i)$ for any index $j' \in \{1, 2, 3\} \setminus \{j\}$ (resp. $j' \in \{4, 5, 6\} \setminus \{j\}$).
Consider finally the vertices \( u_{i,\ell} \) and \( u_{k,j} \), for some \( i, k = 1, 2, \ldots, m \) and \( \ell, j = 1, 2, \ldots, \ell \). If \( i = k \), then without loss of generality \( \ell \in \{1, 2, 3\} \) and \( j \in \{4, 5, 6\} \), since \( u_{i,\ell} \) and \( u_{k,j} \) are non-adjacent. In this case, \( u_{i,\ell'} \in N(u_{i,\ell}) \setminus N(u_{k,j}) \) and \( u_{k,j'} \in N(u_{k,j}) \setminus N(u_{i,\ell}) \), for all indices \( \ell' \in \{1, 2, 3\} \setminus \{\ell\} \) and \( j' \in \{4, 5, 6\} \setminus \{j\} \). Suppose that \( i \neq k \). If \( j \in \{1, 2, 3\} \) (resp. \( j \in \{4, 5, 6\} \)), let \( j' \) be any index of \( \{1, 2, 3\} \setminus \{j\} \) (resp. \( \{4, 5, 6\} \setminus \{j\} \)). Similarly, if \( \ell \in \{1, 2, 3\} \) (resp. \( \ell \in \{4, 5, 6\} \)), let \( \ell' \) be any index of \( \{1, 2, 3\} \setminus \{\ell\} \) (resp. \( \{4, 5, 6\} \setminus \{\ell\} \)). Then, it follows by the construction of \( H_\phi \) from \( G_\phi \) that \( u_{i,\ell'} \in N(u_{i,\ell}) \setminus N(u_{k,j}) \) and \( u_{k,j'} \in N(u_{k,j}) \setminus N(u_{i,\ell}) \).

Therefore, for all possible choices of non-adjacent vertices \( u, v \) in the trapezoid graph \( H_\phi \), we have \( N(u) \setminus N(v) \neq \emptyset \) and \( N(v) \setminus N(u) \neq \emptyset \), which proves the lemma.

**Lemma 13** If \( H_\phi \) is a tolerance graph then it is a bounded tolerance graph.

**Proof.** Suppose that \( H_\phi \) is a tolerance graph, and consider a tolerance representation \( R \) of \( H_\phi \). Due to Lemma 10, we may assume without loss of generality that \( R \) is an inevitable unbounded representation. If \( R \) has no unbounded vertices, then we are done. Otherwise, there exists at least one inevitable unbounded vertex \( v \) in \( R \), which has a hovering vertex \( u \) by Lemma 9, where \( uv \notin E(H_\phi) \). Then, \( N(v) \subseteq N(u) \) in \( H_\phi \) by Lemma 11, which contradicts Lemma 12. Thus, there exists no unbounded vertex in \( R \), i.e. \( H_\phi \) is a bounded tolerance graph.

**Theorem 4** The formula \( \phi \) is NAE-satisfiable if and only if \( H_\phi \) is a tolerance graph.

**Proof.** Suppose that \( \phi \) is NAE-satisfiable. Then, by Theorem 2, \( H_\phi \) is a bounded tolerance graph, and thus, \( H_\phi \) is a tolerance graph. Suppose conversely that \( H_\phi \) is a tolerance graph. Then, by Lemma 13, \( H_\phi \) is a bounded tolerance graph. Thus, \( \phi \) is NAE-satisfiable by Theorem 2.

Therefore, since monotone-NAE-3-SAT is NP-complete, the problem of recognizing tolerance graphs is NP-hard by Theorem 4. Moreover, since the recognition of tolerance graphs lies in NP [17], and since \( H_\phi \) is a trapezoid graph, we obtain the following theorem.

**Theorem 5** It is NP-complete to decide whether a given graph \( G \) is a tolerance graph, even if \( G \) is a trapezoid graph.

### 5 Concluding remarks

In this article we proved that both tolerance and bounded tolerance graph recognition problems are NP-complete, by providing a reduction from the monotone-NAE-3-SAT problem, thus answering a longstanding open question. Furthermore, our reduction implies that, given a trapezoid graph, it is NP-complete to decide whether this graph is a tolerance or a bounded tolerance (i.e. parallelogram) graph. A unit interval representation is an interval representation in which all intervals have the same length. A proper interval representation is one in which no interval is properly contained in another. These terms can apply to both interval graphs and tolerance graphs. It is known that the subclasses of unit and proper interval graphs are equal [27], but the corresponding tolerance subclasses are different [2]. The recognition of unit and of proper tolerance graphs, as well as of any other subclass of tolerance graphs, except bounded tolerance and bipartite tolerance graphs [5], remain interesting open problems [15].
