Algorithmic randomness = incompressibility

Algorithmic randomness = incompressibility

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

• *n*-bit string x is random if $C(x) \approx n$

Algorithmic randomness = incompressibility

- *n*-bit string x is random if $C(x) \approx n$
- ► Randomness deficiency for *n*-bit string: d(x) = n - C(x)

Algorithmic randomness = incompressibility

- *n*-bit string x is random if $C(x) \approx n$
- Randomness deficiency for *n*-bit string:
 d(x) = n C(x)

- Algorithmic randomness = incompressibility
- *n*-bit string x is random if $C(x) \approx n$
- ► Randomness deficiency for *n*-bit string: d(x) = n - C(x)

Most strings of length n are random: the fraction of strings of deficiency > k is about 2^{-k}.

 Two random (incompressible) strings can be dependent

- Two random (incompressible) strings can be dependent
- General notion of independence $I(x : y) \approx 0$

- Two random (incompressible) strings can be dependent
- General notion of independence $I(x : y) \approx 0$
- ► I(x : y) = C(x) C(x|y) measure how useful y is in describing x

- Two random (incompressible) strings can be dependent
- General notion of independence $I(x : y) \approx 0$
- I(x : y) = C(x) − C(x|y) measure how useful y is in describing x
- Special case of incompressible *n*-bit strings: d(x|y) = n − C(x|y) and d(y|x) = n − C(y|x) are small

- Two random (incompressible) strings can be dependent
- General notion of independence $I(x : y) \approx 0$
- ► I(x : y) = C(x) C(x|y) measure how useful y is in describing x
- Special case of incompressible *n*-bit strings:
 d(x|y) = n − C(x|y) and d(y|x) = n − C(y|x) are small

Another measure of dependence: d(x, y) = 2n - C(x, y).

- Two random (incompressible) strings can be dependent
- General notion of independence $I(x : y) \approx 0$
- ► I(x : y) = C(x) C(x|y) measure how useful y is in describing x
- Special case of incompressible *n*-bit strings:
 d(x|y) = n − C(x|y) and d(y|x) = n − C(y|x) are small
- Another measure of dependence: d(x, y) = 2n - C(x, y).
- ► Relation: d(x, y) ≈ d(x) + d(y|x) (folklore enhancement of Kolmogorov–Levin symmetry of information)

• x_1, \ldots, x_N are *n*-bit strings

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

- x_1, \ldots, x_N are *n*-bit strings
- ► each x_i is random and each pair x_i, x_j is independent: d(x_i|x_j) ≤ D [d(x_i, x_j) ≤ D]

- x_1, \ldots, x_N are *n*-bit strings
- ▶ each x_i is random and each pair x_i, x_j is independent: $d(x_i|x_j) \le D [d(x_i, x_j) \le D]$

► How large *N* could be?

- x_1, \ldots, x_N are *n*-bit strings
- ► each x_i is random and each pair x_i, x_j is independent: d(x_i|x_j) ≤ D [d(x_i, x_j) ≤ D]
- How large N could be?
- answer: $N = 2^{D+O(\log D)}$ (for both versions)

- x_1, \ldots, x_N are *n*-bit strings
- ► each x_i is random and each pair x_i, x_j is independent: d(x_i|x_j) ≤ D [d(x_i, x_j) ≤ D]
- How large N could be?
- answer: $N = 2^{D+O(\log D)}$ (for both versions)
- ► Lower bound: choose x_i sequentially, each x_i has small d(x_i|x_j) for all j < i.</p>

- x_1, \ldots, x_N are *n*-bit strings
- ► each x_i is random and each pair x_i, x_j is independent: d(x_i|x_j) ≤ D [d(x_i, x_j) ≤ D]
- How large N could be?
- answer: $N = 2^{D+O(\log D)}$ (for both versions)
- ► Lower bound: choose x_i sequentially, each x_i has small d(x_i|x_j) for all j < i.</p>

 the existence is guaranteed since each x_i disables about 2^{n-D} strings

- x_1, \ldots, x_N are *n*-bit strings
- ► each x_i is random and each pair x_i, x_j is independent: d(x_i|x_j) ≤ D [d(x_i, x_j) ≤ D]
- How large N could be?
- answer: $N = 2^{D+O(\log D)}$ (for both versions)
- ► Lower bound: choose x_i sequentially, each x_i has small d(x_i|x_j) for all j < i.</p>

- the existence is guaranteed since each x_i disables about 2^{n-D} strings
- Problem: what about $d(x_j|x_i)$?

- x_1, \ldots, x_N are *n*-bit strings
- ► each x_i is random and each pair x_i, x_j is independent: d(x_i|x_j) ≤ D [d(x_i, x_j) ≤ D]
- How large N could be?
- answer: $N = 2^{D+O(\log D)}$ (for both versions)
- ► Lower bound: choose x_i sequentially, each x_i has small d(x_i|x_j) for all j < i.</p>
- the existence is guaranteed since each x_i disables about 2^{n-D} strings
- Problem: what about $d(x_j|x_i)$?
- Solution: use only strings with randomness deficiency O(1).

• If x and y have a common prefix of length m, then $d(x|y) \ge m - O(\log m)$

- If x and y have a common prefix of length m, then $d(x|y) \ge m - O(\log m)$
- So if x₁,..., x_N are pairwise independent, then their D + O(log D) bit prefixes are different

- If x and y have a common prefix of length m, then $d(x|y) \ge m - O(\log m)$
- So if x₁,..., x_N are pairwise independent, then their D + O(log D) bit prefixes are different
 so N ≤ 2^{D+O(log D)}.

- If x and y have a common prefix of length m, then $d(x|y) \ge m - O(\log m)$
- So if x₁,..., x_N are pairwise independent, then their D + O(log D) bit prefixes are different
 so N ≤ 2^{D+O(log D)}.

Remark: Lower bound is a kind of generalization of Gilbert bound in coding theory: there we look for strings that have large Hamming distance, now we require more: information distance. (Small Hamming distance \Rightarrow dependence).
