Computability in Europe, 2019

# Kolmogorov complexity

# Kolmogorov complexity

- ▶ Kolmogorov complexity of a string  $x$ : the minimal length of a program (without input) producing  $x$

## Kolmogorov complexity

- ▶ Kolmogorov complexity of a string  $x$ : the minimal length of a program (without input) producing  $x$
- ▶  $C_U(x) = \min\{|p| : U(p) = x\}$ :  $U$  is the interpreter,  $p$  is the program

# Kolmogorov complexity

- ▶ Kolmogorov complexity of a string  $x$ : the minimal length of a program (without input) producing  $x$
- ▶  $C_U(x) = \min\{|p| : U(p) = x\}$ :  $U$  is the interpreter,  $p$  is the program
- ▶ depends on  $U$

## Kolmogorov complexity

- ▶ Kolmogorov complexity of a string  $x$ : the minimal length of a program (without input) producing  $x$
- ▶  $C_U(x) = \min\{|p| : U(p) = x\}$ :  $U$  is the interpreter,  $p$  is the program
- ▶ depends on  $U$
- ▶ there exists optimal  $U$  that makes  $C_U$  minimal up to  $O(1)$

# Kolmogorov complexity

- ▶ Kolmogorov complexity of a string  $x$ : the minimal length of a program (without input) producing  $x$
- ▶  $C_U(x) = \min\{|p| : U(p) = x\}$ :  $U$  is the interpreter,  $p$  is the program
- ▶ depends on  $U$
- ▶ there exists optimal  $U$  that makes  $C_U$  minimal up to  $O(1)$

$$\exists U \forall U' \exists c \forall x [C_U(x) \leq C_{U'}(x) + c]$$

# Kolmogorov complexity

- ▶ Kolmogorov complexity of a string  $x$ : the minimal length of a program (without input) producing  $x$
- ▶  $C_U(x) = \min\{|p| : U(p) = x\}$ :  $U$  is the interpreter,  $p$  is the program
- ▶ depends on  $U$
- ▶ there exists optimal  $U$  that makes  $C_U$  minimal up to  $O(1)$ 
$$\exists U \forall U' \exists c \forall x [C_U(x) \leq C_{U'}(x) + c]$$
- ▶ fix some  $U$  and forget about it

# Non-computability

# Non-computability

- ▶ Kolmogorov complexity is not computable

## Non-computability

- ▶ Kolmogorov complexity is not computable
- ▶ Berry – Chaitin argument:  
«the first string of complexity more than  $10^{10^{10}}$ »

## Non-computability

- ▶ Kolmogorov complexity is not computable
- ▶ Berry – Chaitin argument:  
«the first string of complexity more than  $10^{10^{10}}$ »
- ▶ moreover, every computable lower bound is trivial, even if partial

## Non-computability

- ▶ Kolmogorov complexity is not computable
- ▶ Berry – Chaitin argument:  
«the first string of complexity more than  $10^{10^{10}}$ »
- ▶ moreover, every computable lower bound is trivial, even if partial
- ▶ Kolmogorov complexity is not **generically computable**

# Non-computability

- ▶ Kolmogorov complexity is not computable
- ▶ Berry – Chaitin argument:  
«the first string of complexity more than  $10^{10^{10}}$ »
- ▶ moreover, every computable lower bound is trivial, even if partial
- ▶ Kolmogorov complexity is not **generically computable**
- ▶ **coarse** computability: a **total** algorithm that makes **few** errors

## Non-computability

- ▶ Kolmogorov complexity is not computable
- ▶ Berry – Chaitin argument:  
«the first string of complexity more than  $10^{10^{10}}$ »
- ▶ moreover, every computable lower bound is trivial, even if partial
- ▶ Kolmogorov complexity is not **generically computable**
- ▶ **coarse** computability: a **total** algorithm that makes **few errors**
- ▶ total function  $f(\cdot)$  is *coarsely computable* if there is a total computable  $F$  such that the fraction of errors converges to 0:

$$\frac{\#\{i : i < N \text{ and } f(i) \neq F(i)\}}{N} \rightarrow 0 \quad \text{as } N \rightarrow \infty$$

# Approximation errors

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$
- ▶ a computable upper bound for  $C \dots$

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$
- ▶ a computable upper bound for  $C \dots$
- ▶  $\dots$  therefore the fraction of errors does not converge to 0

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$
- ▶ a computable upper bound for  $C \dots$
- ▶  $\dots$  therefore the fraction of errors does not converge to 0
- ▶ improvements:

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$
- ▶ a computable upper bound for  $C \dots$
- ▶  $\dots$  therefore the fraction of errors does not converge to 0
- ▶ improvements:  $\dots$  is separated from 0

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$
- ▶ a computable upper bound for  $C \dots$
- ▶  $\dots$  therefore the fraction of errors does not converge to 0
- ▶ improvements:  $\dots$  is separated from 0
- ▶ what if we approximate complexity values?

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$
- ▶ a computable upper bound for  $C \dots$
- ▶  $\dots$  therefore the fraction of errors does not converge to 0
- ▶ improvements:  $\dots$  is separated from 0
- ▶ what if we approximate complexity values?
- ▶ difficulty in the Medvedev lattice

## Approximation errors

- ▶ **Theorem:** Kolmogorov complexity function is not coarsely computable
- ▶  $C^t(x)$  is the minimal length of a program that produces  $x$  in time at most  $t$
- ▶ a computable upper bound for  $C \dots$
- ▶  $\dots$  therefore the fraction of errors does not converge to 0
- ▶ improvements:  $\dots$  is separated from 0
- ▶ what if we approximate complexity values?
- ▶ difficulty in the Medvedev lattice
- ▶ logical implications

Trade-off: precision vs #errors

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$
- ▶  $C(x) < |x| - d$ : compressible (by  $d$ ) strings

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$
- ▶  $C(x) < |x| - d$ : compressible (by  $d$ ) strings are rare (fraction:  $\approx 2^{-d}$ )

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$
- ▶  $C(x) < |x| - d$ : compressible (by  $d$ ) strings are rare (fraction:  $\approx 2^{-d}$ )
- ▶ increasing  $d$ : lower precision required, less errors

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$
- ▶  $C(x) < |x| - d$ : compressible (by  $d$ ) strings are rare (fraction:  $\approx 2^{-d}$ )
- ▶ increasing  $d$ : lower precision required, less errors
- ▶ «Theorem»: No approximation is better than length: the same trade-off

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$
- ▶  $C(x) < |x| - d$ : compressible (by  $d$ ) strings are rare (fraction:  $\approx 2^{-d}$ )
- ▶ increasing  $d$ : lower precision required, less errors
- ▶ «Theorem»: No approximation is better than length: the same trade-off
- ▶ technical: one-sided error  $d$  is two-sided error  $d/2$ : take  $C(x) - d/2$

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$
- ▶  $C(x) < |x| - d$ : compressible (by  $d$ ) strings are rare (fraction:  $\approx 2^{-d}$ )
- ▶ increasing  $d$ : lower precision required, less errors
- ▶ «Theorem»: No approximation is better than length: the same trade-off
- ▶ technical: one-sided error  $d$  is two-sided error  $d/2$ : take  $C(x) - d/2$
- ▶ Let  $e(n)$  and  $d(n)$  be two total computable functions with integer values,  $e(n) - 2d(n) \rightarrow \infty$  and  $e(n) \leq n$ . Then there is no computable function  $\tilde{C}(x)$  that is  $(d(n), e(n))$ -approximation for  $C(x)$  on  $n$ -bit strings.

## Trade-off: precision vs #errors

- ▶ length is an upper bound:  $C(x) \leq |x| + O(1)$
- ▶  $C(x) < |x| - d$ : compressible (by  $d$ ) strings are rare (fraction:  $\approx 2^{-d}$ )
- ▶ increasing  $d$ : lower precision required, less errors
- ▶ «Theorem»: No approximation is better than length: the same trade-off
- ▶ technical: one-sided error  $d$  is two-sided error  $d/2$ : take  $C(x) - d/2$
- ▶ Let  $e(n)$  and  $d(n)$  be two total computable functions with integer values,  $e(n) - 2d(n) \rightarrow \infty$  and  $e(n) \leq n$ . Then there is no computable function  $\tilde{C}(x)$  that is  $(d(n), e(n))$ -approximation for  $C(x)$  on  $n$ -bit strings.
- ▶  $(d, e)$ -approximation: deviation  $< d$  except for  $2^{-e}$ -fraction

# Finite version and proof idea

## Finite version and proof idea

- ▶ looking for a program that approximates complexity for  $n$ -bit strings

## Finite version and proof idea

- ▶ looking for a program that approximates complexity for  $n$ -bit strings
- ▶ exists (just a table)

## Finite version and proof idea

- ▶ looking for a program that approximates complexity for  $n$ -bit strings
- ▶ exists (just a table)
- ▶ ... but has high complexity

## Finite version and proof idea

- ▶ looking for a program that approximates complexity for  $n$ -bit strings
- ▶ exists (just a table)
- ▶ ... but has high complexity
- ▶  $(d, e)$ -approximation for  $n$ -bit strings requires complexity about  $e - 2d$

## Finite version and proof idea

- ▶ looking for a program that approximates complexity for  $n$ -bit strings
- ▶ exists (just a table)
- ▶ ... but has high complexity
- ▶  $(d, e)$ -approximation for  $n$ -bit strings requires complexity about  $e - 2d$
- ▶ why? knowing (a) the approximation; (b) number of places where approximation has large error [ $n - e$  bits] we can find those places and then find a string of complexity at least  $n - 2d$ , so

$$(\text{complexity of the approximation}) + (n - e) \geq n - 2d$$

## Finite version and proof idea

- ▶ looking for a program that approximates complexity for  $n$ -bit strings
- ▶ exists (just a table)
- ▶ ... but has high complexity
- ▶  $(d, e)$ -approximation for  $n$ -bit strings requires complexity about  $e - 2d$
- ▶ why? knowing (a) the approximation; (b) number of places where approximation has large error [ $n - e$  bits] we can find those places and then find a string of complexity at least  $n - 2d$ , so
$$(\text{complexity of the approximation}) + (n - e) \geq n - 2d$$
- ▶ many technical details omitted (“one-sided” errors, logarithmic terms, etc.)

# Approximation as a mass problem

## Approximation as a mass problem

- ▶ mass problem (Medvedev): a set of total functions (“solutions”)

## Approximation as a mass problem

- ▶ mass problem (Medvedev): a set of total functions (“solutions”)
- ▶ approximating complexity: a set of good approximations

## Approximation as a mass problem

- ▶ mass problem (Medvedev): a set of total functions (“solutions”)
- ▶ approximating complexity: a set of good approximations
- ▶ Medvedev reducibility  $\mathcal{A} \leq \mathcal{B}$ : there is a machine  $M$  such that  $M^B \in \mathcal{A}$  for each  $B \in \mathcal{B}$

## Approximation as a mass problem

- ▶ mass problem (Medvedev): a set of total functions (“solutions”)
- ▶ approximating complexity: a set of good approximations
- ▶ Medvedev reducibility  $\mathcal{A} \leq \mathcal{B}$ : there is a machine  $M$  such that  $M^B \in \mathcal{A}$  for each  $B \in \mathcal{B}$
- ▶ **Theorem**: halting problem is Medvedev-reducible to the problem of approximating complexity (with any given non-trivial precision)

## Approximation as a mass problem

- ▶ mass problem (Medvedev): a set of total functions (“solutions”)
- ▶ approximating complexity: a set of good approximations
- ▶ Medvedev reducibility  $\mathcal{A} \leq \mathcal{B}$ : there is a machine  $M$  such that  $M^B \in \mathcal{A}$  for each  $B \in \mathcal{B}$
- ▶ **Theorem**: halting problem is Medvedev-reducible to the problem of approximating complexity (with any given non-trivial precision)
- ▶ even separating incompressible strings from 100-fold compressible is above the halting problem

# Approximation and logic

## Approximation and logic

- ▶ for every string  $x$  and integer  $n$ : arithmetical statement  $C(x) \geq n$

## Approximation and logic

- ▶ for every string  $x$  and integer  $n$ : arithmetical statement  $C(x) \geq n$
- ▶ they are  $\Pi_1$ -statements

## Approximation and logic

- ▶ for every string  $x$  and integer  $n$ : arithmetical statement  $C(x) \geq n$
- ▶ they are  $\Pi_1$ -statements
- ▶ a lot of true statements (most of  $n$ -bit strings are almost incompressible)

## Approximation and logic

- ▶ for every string  $x$  and integer  $n$ : arithmetical statement  $C(x) \geq n$
- ▶ they are  $\Pi_1$ -statements
- ▶ a lot of true statements (most of  $n$ -bit strings are almost incompressible)
- ▶ none of them provable (except for bounded values of  $n$ )

## Approximation and logic

- ▶ for every string  $x$  and integer  $n$ : arithmetical statement  $C(x) \geq n$
- ▶ they are  $\Pi_1$ -statements
- ▶ a lot of true statements (most of  $n$ -bit strings are almost incompressible)
- ▶ none of them provable (except for bounded values of  $n$ )
- ▶ what if we add them as axioms?

## Approximation and logic

- ▶ for every string  $x$  and integer  $n$ : arithmetical statement  $C(x) \geq n$
- ▶ they are  $\Pi_1$ -statements
- ▶ a lot of true statements (most of  $n$ -bit strings are almost incompressible)
- ▶ none of them provable (except for bounded values of  $n$ )
- ▶ what if we add them as axioms?
- ▶ **Theorem**: adding axioms  $C(x) \geq |x|/2$  for every incompressible string  $x$ , we may derive all true universal statements

## Approximation and logic

- ▶ for every string  $x$  and integer  $n$ : arithmetical statement  $C(x) \geq n$
- ▶ they are  $\Pi_1$ -statements
- ▶ a lot of true statements (most of  $n$ -bit strings are almost incompressible)
- ▶ none of them provable (except for bounded values of  $n$ )
- ▶ what if we add them as axioms?
- ▶ **Theorem**: adding axioms  $C(x) \geq |x|/2$  for every incompressible string  $x$ , we may derive all true universal statements
- ▶ (a logic counterpart of the difficulty of separation)

Thanks!
