Revision History ISO-26262

Revision	Changes	Status/ Date
24	Modifications to improve the readability and comprehension of the content. Approved by Lucille Woo. All technical enhancements, changes, and fixes listed in the <i>Tessent Release Notes</i> for this product are reflected in this document. Approved by Ron Press.	Released Sep 2021
23	Modifications to improve the readability and comprehension of the content. Approved by Lucille Woo. All technical enhancements, changes, and fixes listed in the <i>Tessent Release Notes</i> for this product are reflected in this document. Approved by Ron Press.	Released Jun 2021
22	Modifications to improve the readability and comprehension of the content. Approved by Lucille Woo. All technical enhancements, changes, and fixes listed in the <i>Tessent Release Notes</i> for this product are reflected in this document. Approved by Ron Press.	Released Apr 2021
21	Modifications to improve the readability and comprehension of the content. Approved by Lucille Woo. All technical enhancements, changes, and fixes listed in the <i>Tessent Release Notes</i> for this product are reflected in this document. Approved by Ron Press.	Released Mar 2021

Author: In-house procedures and working practices require multiple authors for documents. All associated authors for each topic within this document are tracked within the Siemens documentation source. For specific topic authors, contact Siemens Digital Industries Software documentation department.

Revision History: Released documents include a revision history of up to four revisions. For earlier revision history, refer to earlier releases of documentation on Support Center.

Overview

Application commands are provided for Tessent Shell, as well as for the following products:

- Tessent BoundaryScan is a complete solution for the creation and integration of boundary scan cells and related control logic for embedded test and diagnosis of integrated circuit I/Os, as well as test and diagnosis of board-level interconnects between ICs. Tessent BoundaryScan provides a completely automated solution for adding standard boundary scan support to ICs of any size or complexity, reducing IC engineering development effort and improving time-to-market.
- Tessent Diagnosis is a sophisticated diagnosis tool used at different stages of test to help characterize and locate defects in manufactured chips. It is for users who need to shorten the time it takes to perform yield ramp, yield learning and customer return analysis. The unique advanced diagnosis capabilities it provides are also available in Tessent TestKompress.
- Tessent FastScan is a comprehensive combinational Automatic Test Pattern Generation (ATPG) system optimized for full-scan designs. It offers high speed and accurately measured high test coverage to guarantee your product quality and reliability.
- Tessent IJTAG is the Siemens EDA implementation of the [IEEE 1687-2014](#) (IJTAG) standard and supports reading Instrument Connectivity Language (ICL), performing automatic retargeting of IJTAG-specific PDL commands such as iWrite and iRead, and

writing out the retargeted PDL patterns in many different ATE tester specific formats and as Verilog HDL simulation test benches. See the [Tessent IJTAG User's Manual](#) for complete information.

- Tessent LogicBIST contains all of the functionality needed to implement the Hybrid TK/LBIST Flow for your design. The tool enables you to share the logic between EDT and LBIST controllers that can be configured to work either in EDT or LBIST mode. The product enables you to create a BIST-ready design, generates the hybrid IP, performs fault simulation, and creates top-level serial patterns to validate the LBIST mode.
- Tessent MemoryBIST provides a complete solution for at-speed testing, diagnosis, repair, debug, and characterization of embedded memories. The solution's architecture is hierarchical, enabling BIST and self-repair capabilities to be added to individual cores as well as at the top level.
- Tessent MissionMode provides a combination of automation and on-chip IP for enabling semiconductor chips throughout an automotive (or other safety-critical) electronics system to be tested and diagnosed at any point during the system's functional operation.
- Tessent SiliconInsight provides interactive capabilities for testing, debugging, and characterizing BIST-tested memories and logic, IEEE 1687 IJTAG instruments, and ATPG patterns. It also facilitates on-tester data collection and diagnosis for BIST-tested memories and logic.
- Tessent DesignEditor is a less expensive product that provides access only to design introspection and editing features. This product only provides access to the dft context (commands labeled "dft" or "all contexts").
- Tessent Scan is an internal scan synthesis tool that identifies and inserts scan and test circuitry into your design. For more information, refer to the *Tessent Scan and ATPG User's Manual*.
- Tessent ScanPro is a tool for inserting test logic to make the design scan and BIST ready. It includes the scan stitching capabilities that are part of Tessent Scan, but in addition includes capabilities for inserting test points to improve pattern counts and test coverage, X-bounding to prevent X's from propagating in the design, and inserts logic to isolate false and multicycle paths.
- Tessent TestKompress uses patented scan EDT™ (Embedded Deterministic Test) technology and many of the industry leading ATPG features of Tessent FastScan, to reduce scan data volume and test time by many times over Tessent FastScan ATPG. It is for users who need greater reductions in ATE memory and time requirements than are available with any other full-scan ATPG tool.
- Tessent Visualizer, which is built into all of these tools, is a schematic and data viewing utility. Tessent Visualizer adds the ability to graphically investigate and interact with

designs, making it easier to debug problems. For more information, see “[Tessent Visualizer](#)” in the *Tessent Shell User’s Manual*.

In Tessent Shell, the term “context” refers to a broad category of functionality that often corresponds to a specific product and a license feature, such as Tessent FastScan. By setting the context, you indicate the type of task you want Tessent Shell to perform. For more information about Tessent Shell contexts, refer to the “[Context and System Modes](#)” section in the *Tessent Shell User’s Manual*.

Note

 Design editing commands are not available when using product licenses for Tessent FastScan and Tessent Scan. For more information about the design editing commands, refer to “[Design Editing](#)” in the *Tessent Shell User’s Manual*.

Product Introduction

Tessent Shell is a Tcl shell environment and design data model that provides a unified Tcl command set and command naming conventions.

Tessent Shell also provides access to the following products:

Tessent BoundaryScan	60
Tessent Diagnosis	61
Tessent FastScan and Tessent TestKompres	62
Tessent IJTAG	64
Tessent LogicBIST	65
Tessent MemoryBIST	65
Tessent MissionMode	66
Tessent Scan	67
Tessent ScanPro	68
Tessent SiliconInsight	68
Tessent DesignEditor	69

Tessent BoundaryScan

Tessent BoundaryScan is a complete solution for the creation and integration of boundary scan cells and related control logic for embedded test and diagnosis of integrated circuit I/Os, as well as test and diagnosis of board-level interconnects between ICs. Tessent BoundaryScan provides a completely automated solution for adding standard boundary scan support to ICs of any size or complexity, reducing IC engineering development effort and improving time-to-market.

Tessent BoundaryScan supports standard 1149.1 boundary scan cells, 1149.1 custom boundary scan cells, and optionally 1149.6 boundary scan cells for differential I/O cells driving AC-coupled nets. It also provides a unique 1149.1-based solution for contactless testing of I/Os. For complete information, refer to the *Tessent BoundaryScan User's Manual*.

Tessent BoundaryScan Inputs

To use this flow, you must have either an RTL or a gate-level netlist with I/O pads already inserted into the design. For an RTL netlist, you must have the Tessent cell library or the pad library for the pad cells. For a gate-level netlist, you must have the Tessent cell library or the ATPG library for the standard cells, in addition to the Tessent cell library for the I/O pad cells. The pad library supported by Tessent BoundaryScan-LV is natively supported in Tessent Shell if the Tessent cell library for the I/O pad cells is not present.

Tessent BoundaryScan Outputs

The tool creates and interconnects RTL-level boundary scan logic compliant with the IEEE 1149.1-2001 standard.

- **Instruction Support** — Full support of required IEEE standards 1149.1 instructions.
- **Extension Support** — Support of base extensions to IEEE 1149.1, such as the Device ID register.
- **Compliant Verilog** — Generation of Verilog (IEEE 1364-2001) that is compliant with Questa® SIM (Verilog), Synopsys' Design Compiler, and other industry synthesis tools.
- **RTL-Level Boundary Scan Generation** — Insertion and interconnection of boundary scan circuitry at the RTL level, moving generation of test circuitry to earlier in the design process.
- **Customized Boundary Scan** — Generation of default or user-customized boundary scan architectures.
- **Automatic Connection** — Automatic connection of boundary scan to internal scan logic.
- **Test Bench Generation** — Generation of a test bench to test the boundary scan logic after interconnection with the core application logic.
- **Test Vector Generation** — Generation of boundary scan test vectors in a variety of ASIC vendor test data formats, as well as ASCII, binary, STIL, WGL and other pattern formats.
- **Setup File Generation** — Generation of ATPG setup files, for designs with generated boundary scan circuitry controlling internal scan circuitry.
- **Compliant BSDL** — Production of BSDL output that is compliant with IEEE standard IEEE 1149.1-2001 specification.

Tessent Diagnosis

Tessent Diagnosis-specific features include many capabilities.

Some of these capabilities are:

- Fault model independent analysis for suspect identification, suspect scoring, and classification.
- Logic and chain diagnosis.
- Direct diagnosis with compressed patterns.
- Links to Calibre® for physical view.

Tessent Diagnosis Inputs

Tessent Diagnosis has the following inputs:

- **Design** — This must be a flattened design, created previously using the [write_flat_model](#) command in Tessent FastScan or Tessent TestKompress.
- **Test Patterns** — STIL, WGL, binary or ASCII version of the patterns applied on the tester.
- **Failure file** — This file contains ATE failure data presented in the correct Tessent failure file format for the [diagnose_failures](#) command.

Tessent Diagnosis Outputs

Tessent Diagnosis produces the following outputs:

- **Failure Diagnosis Report** — This is a human-readable diagnosis report that is displayed onscreen or written in ASCII format to a file. Additionally, the report can be written to a file in Comma Separated Value (CSV) format.

Tessent FastScan and Tessent TestKompress

Tessent FastScan and Tessent TestKompress share a great deal of functionality. Tessent TestKompress contains the entire Tessent FastScan feature set (the “patterns -scan” context), and in addition provides functionality for EDT IP creation (the “dft -edt” context).

Both products share the following features:

- Can be used within a Tessent flow or as a point tool in other design flows.
- Contain an internal high-speed fault simulator.
- Produce a number of standard test pattern data formats.
- Contain a powerful design rules checker.
- Read most standard gate-level netlists.
- Produce very high coverage test pattern sets for full-scan and scan-sequential designs. Scan-sequential designs contain well-behaved sequential scan circuitry, including non-scan latches, sequential memories, and limited sequential depth.
- Contain functionality for handling embedded RAM and ROM.
- Support the same pattern types and fault models.
- Provide the same test coverage.
- Provide the same diagnostics.

- Contain the same command set, with the exception that Tessent TestKompress contains additional commands for EDT IP creation and use.

In addition to the previous features, Tessent TestKompress includes the following:

- Increases production throughput: scan test time is much shorter than any other scan methodology.

Tessent FastScan and Tessent TestKompress Inputs

Tessent FastScan and Tessent TestKompress have the following inputs:

- **Design** — The supported netlist formats are: gate-level Verilog, RTL Verilog, RTL System Verilog, and RTL VHDL.
- **Test Procedure File** — This file defines the operation of the scan circuitry in your design. You can generate the file by hand or by using the `write_atpg_setup` command in Tessent Scan.
- **Library** — This file contains model descriptions for all library cells used in your design.
- **Test Patterns** — This is a set of externally generated test patterns that you can use as the pattern source for simulation.

Tessent TestKompress has the following inputs:

- EDT IP Creation Phase:
 - **Design** — This must be a gate-level netlist with scan. The supported netlist format is Verilog.
 - **Test Procedure File** — This file defines the operation of the scan circuitry in your design. You can generate the file by hand or by using the `write_atpg_setup` command in Tessent Scan.
 - **Library** — This file contains model descriptions for all library cells used in your design.
- EDT Pattern Generation Phase:
 - **Design** — This must be a scan-inserted, gate-level netlist with EDT circuitry. The supported netlist format is Verilog.
 - **EDT Dofile** — Created by Tessent TestKompress in the IP Creation Phase, this file contains setup commands for the Pattern Generation Phase.
 - **EDT Test procedure file** — Created by Tessent TestKompress in the IP Creation Phase, this file contains test procedure steps for the Pattern Generation Phase.

- **Library** — This file contains model descriptions for all library cells used in your design.

Tessent FastScan and Tessent TestKompress Outputs

Tessent FastScan and Tessent TestKompress produce the following outputs:

- **Test Patterns** — This file set contains test patterns in one or more of the supported simulator or ASIC vendor pattern formats. For more information on the available test pattern formats, refer to the [write_patterns](#) command reference page within this manual, or the “[How to Save the Test Patterns](#)” section in the *Tessent Scan and ATPG User’s Manual*.
- **ATPG Information Files** — These files contain session information that you can save using various commands.
- **Fault List** — This is an ASCII file that contains internal fault information in the standard Tessent fault format.

Tessent TestKompress produces the following outputs:

- EDT IP Creation Phase:
 - **EDT IP Files** — These files contain the EDT IP described in Verilog or VHDL RTL, as well as connectivity and a black box representation of the core design.
 - **Design Compiler Synthesis Script** — This is a synthesis script, typically used as a template for synthesizing the EDT IP into the design.
 - **EDT Dofile** — This file contains setup commands for the EDT Pattern Generation Phase.
 - **EDT Test Procedure File** — This file contains test procedure steps for the Pattern Generation Phase.
 - **Bypass Files** — These files consist of a dofile and a test procedure file for optionally performing Tessent FastScan ATPG on the design with EDT.
- EDT Pattern Generation Phase:
 - **Test Patterns** — This file set contains test patterns in one or more of the supported simulator or ASIC vendor pattern formats. For more information on the available test pattern formats, refer to the [write_patterns](#) command description in this manual.

Tessent IJTAG

Tessent IJTAG is the Siemens EDA implementation of the IEEE 1687-2014 (IJTAG) standard for PDL command retargeting and ICL extraction.

For complete information, refer to [IEEE 1687-2014 \(IJTAG\)](#) term in the *Tessent Glossary* and to the [Tessent IJTAG User’s Manual](#).

Tessent IJTAG Inputs

Tessent IJTAG has the following input:

- **ICL Files** — Instrument Connectivity Language (ICL) descriptions of your design.

Tessent IJTAG Outputs

Tessent IJTAG produces the following outputs:

- **Test Patterns** — Retargeted PDL patterns in many different ATE tester specific formats and Verilog HDL simulation test benches.
- **Extracted ICL Files** — Top-level ICL expressing the interconnection of IJTAG instruments within a design netlist.

Tessent LogicBIST

Tessent LogicBIST contains all the features that are needed to implement Hybrid TK/LBIST Flow in a design.

The product includes the following features:

- Insertion of DFT into the design to make it BIST-ready. This involves scan stitching, x-bounding, and bounding of multicycle and false paths.
- Test point insertion to improve the random pattern testability of the design.
- Hybrid TK/LBIST generation and insertion into the incoming design. This includes sharing the logic between the EDT and LBIST controllers, thereby reducing the overall area overhead. Additionally, the tool also generates logic that enables you to do low power shift during LBIST.
- IJTAG network insertion and extraction, which is necessary to set up Logic BIST and observe the MISR signature.
- Fault simulation of the pseudo-random patterns applied during an LBIST session.
- Generation of top-level patterns that enables merging of patterns for multiple LBIST controllers.

Tessent MemoryBIST

Tessent MemoryBIST provides a complete solution for at-speed testing, diagnosis, repair, debug, and characterization of embedded memories. The solution's architecture is hierarchical, enabling BIST and self-repair capabilities to be added to individual cores as well as at the top level.

For complete information, refer to the [Tessent MemoryBIST User's Manual](#).

Tessent MemoryBIST Inputs

To insert memory BIST into your design, you must have either an RTL or a gate-level netlist as well as memory BIST libraries.

If the design contains standard cells, the Tessent cell library or ATPG library is also required. For other IP blocks that do not have either RTL or library models, the simulation model can be loaded using the [read_verilog](#) or [read_vhdl](#) command with the `-interface_only` option. This instructs the tool to ignore the internals of all modules specified in the filename argument and extract only the module port definitions and parameters.

Tessent MemoryBIST Outputs

Using Tessent MemoryBIST, you can perform the following:

- Test multiple memories using one memory BIST controller that has one or more BIST steps, where BIST steps are run in sequence.
- Test memories in parallel in one BIST step or in sequence in several BIST steps.
- Define one or more custom test memory algorithms that are hard coded into the memory BIST controller.
- Choose memory test algorithms from the Tessent library of algorithms to be hard coded into the memory BIST controller.
- Run the memory BIST controller for all steps with the specific algorithms assigned at generation time (default configuration).
- Run the memory BIST controller in diagnostic mode where you can freeze on a specific BIST step, specific memory test port, or specific error count.
- Select a hard-coded memory BIST algorithm to be applied to a specific memory BIST step at the tester.
- Select an algorithm from a library of algorithms to be applied to a specific memory BIST step.
- Define a custom algorithm at tester time to be applied to a specific memory BIST step.
- Perform repair analysis on memories implementing different redundancy schemes such as row only, column only, or row and column.

Tessent MissionMode

Tessent MissionMode enables communication between any external CPU bus and all on-chip test resources for system-controlled on-line test and diagnosis. The on-chip test resources can consist of any Tessent BIST or DFT capabilities (such as MemoryBIST, LogicBIST or EDT logic) or any third-party JTAG-compliant instruments.

This product is part of the Mentor Safe tool suite that enables ISO 26262-compliant designs for advanced driver-assistance systems (ADAS) and autonomous driving capabilities for passenger cars, as well as for other safety-critical applications such as aerospace and medicine. The tool targets IC reliability by providing advanced self-test and monitoring capabilities once the IC is packaged and deployed in the device.

Tessent Scan

Tessent Scan tool-specific features include features that support scan insertion.

Specifically, Tessent Scan supports the following functionality:

- Support for full-scan identification and insertion.
- Support for Mux-scan methodology.
- Powerful design rules checking.
- Automatic generation of the scan setup dofile and the test procedure files for use downstream in your flow with Tessent FastScan and Tessent TestKompress ATPG products.
- Display of a variety of information—from design and debugging information to statistical reports for the test set you generate.

Tessent Scan Inputs

Tessent Scan has the following inputs:

- [Design Netlist](#) — In Verilog format.
- [Test Procedure File](#) — Required if you have existing scan circuitry in your design. The test procedure file defines the operation of existing scan circuitry. See also “[How to Specify Existing Scan Information](#)” in the *Tessent Scan and ATPG User's Manual*.
- [DFT Library](#) — Contains the model descriptions for all library cells used in your design, along with the model descriptions for all the scan replacement cells.
- **Command Dofile** — A text file containing a list of Tessent Scan commands. You can also enter these commands interactively.

Tessent Scan Outputs

Tessent Scan produces the following outputs:

- [Design Netlist](#) — A scan version of your design netlist that can be in Verilog format.
- [ATPG Setup Files](#) — The test procedure file, which defines the operation of the scan circuitry in your design, and a dofile for setting up the design and scan circuitry information for ATPG operations.

Tessent ScanPro

Tessent ScanPro includes features that are necessary for scan insertion (part of Tessent Scan), as well as all the advanced DFT insertion features to facilitate scan testing and Logic BIST.

Specifically, Tessent ScanPro supports the following functionality:

- Includes all features that are part of Tessent Scan.
- Generation of test points for pattern reduction as well as test coverage improvement.
- Ability to identify and bound all Xs in the designs. This is needed to reduce the number of Xs that can propagate into the design and can affect compression as well as Logic BIST runs.
- Ability to read in SDC and add DFT to block transitions propagated through Multicycle Paths (MCPs) and False Paths (FPs) from being captured on scan cells.

Tessent ScanPro Inputs

These are the same as Tessent Scan.

Tessent ScanPro Outputs

These are the same as Tessent Scan, with the addition of the following:

- Scan Setup Files — This is the dofile and test procedure file that are required to perform incremental scan stitching of the test point flops.
- Test Point Dofile — This is the file that writes out all the test points that the tool is ready to insert into the design. This is needed when you want just to perform the analysis in the current session but would like to get back to insertion at a later time.

Tessent SiliconInsight

Tessent SiliconInsight provides interactive capabilities for testing, debugging, and characterizing BIST-tested memories and logic, IEEE 1687 IJTAG instruments, and ATPG patterns. It also facilitates on-tester data collection and diagnosis for BIST-tested memories and logic.

For complete information, refer to the [Tessent SiliconInsight User's Manual for Tessent Shell](#).

Tessent SiliconInsight operates within the Tessent Shell environment. The tool uses an open ATE interface to interact with embedded instruments for both pre-silicon, desktop, and ATE applications. The open interface is called the Characterization and Debug Package (CDP). The CDP contains test patterns, procedural data and side files that enable access and control of any instrument at any hierarchy level.

For more detailed characterization activities, you can also control instruments such as power supplies and clock generators with interface buses implemented according to the General Purpose Interface Bus (GPIB) standard IEEE-488. To do this, connect a USB-to-GPIB adaptor to a GPIB instrument, which you then connect to the performance board.

Tessent DesignEditor

Tessent DesignEditor features contain a subset of Tessent Shell features.

The product includes the following features:

- Access to design introspection and editing features while consuming a less expensive product license.
- Access to the commands that can operate in the dft context (commands labeled “dft” or “all contexts”).

Tessent DesignEditor Inputs

Tessent DesignEditor has the following inputs:

- **Design** — The supported netlist formats are: gate-level Verilog, RTL Verilog, RTL System Verilog, and RTL VHDL.
- **Library** — This file contains model descriptions for all library cells used in your design.

Tessent DesignEditor Outputs

Tessent DesignEditor produces the following outputs:

- **Design** — The supported netlist formats are: gate-level Verilog, RTL Verilog, RTL System Verilog, and RTL VHDL.

Chapter 2

Tool Invocations

Tool invocation commands invoke tools that create, edit, manipulate, or diagnose test patterns for DFT applications. These commands are issued from the input window of your Linux workstation and, by default, open in a command line session.

Tool Invocation Command Descriptions	72
create_skeleton_design	73
stil2mgc	75
tessent	82
tessent -diagserver	83
tessent -shell	86
tessent -siliconinsight	90
tessent -visualizer	91
tessent -yieldinsight	93

Tool Invocation Command Descriptions

The notational conventions used to describe the tool invocation commands are the same for all products. Do not enter any of the special notational characters (such as, {}, [], or |) when typing the command.

Table 2-1 describes the notational conventions used in this manual.

Table 2-1. Conventions for Command Line Syntax

Convention	Example	Usage
UPPercase	-Static	Required argument letters are in uppercase; in most cases, you may omit lowercase letters when entering literal arguments, and you need not enter in uppercase. Arguments are normally case insensitive.
Boldface	set_fault_mode <u>Uncollapsed</u> Collapsed	A boldface font indicates a required argument.
[]	exit [-force]	Square brackets enclose optional arguments. Do not enter the brackets.
<i>Italic</i>	dofile <i>filename</i>	An italic font indicates a user-supplied argument.
{ }	add_fault_sites {- ALI -UNDEFINED_Cells }[-VERBose]	Braces enclose arguments to show grouping. Do not enter the braces.
	add_fault_sites {- ALI -UNDEFINED_Cells }[-VERBose]	The vertical bar indicates an either/or choice between items. Do not include the bar in the command.
Underline	set_dofile_abort <u>ON</u> OFF	An underlined item indicates either the default argument or the default value of an argument.
...	add_clocks <i>off_state pin_list</i> ...	An ellipsis follows an argument that may appear more than once. Do not include the ellipsis when entering commands.

create_skeleton_design

Invokes Tessent TestKompress and creates files necessary to integrate Tessent TestKompress logic (TestKompress logic) into a design at the RTL stage.

Usage

```
create_skeleton_design -i skeleton_design_input_file
  [-o output_file_prefix]
  [-simulation_library]
  [-design_interface filename]
  [-module_name module_name]
  [-help [-verbose]]
```

Description

Invokes Tessent TestKompress and creates files necessary to integrate Tessent TestKompress logic (TestKompress logic) into a design at the RTL stage.

This command requires a special design skeleton input file that you create manually. For more information about this file, see “[Integrating Compression at the RTL Stage](#)” in the *Tessent TestKompress User’s Manual*.

Arguments

- *-i skeleton_design_input_file*
A required switch and string pair that specifies the pathname of the skeleton design input file.
- *-o output_file_prefix*
An optional switch and string pair that specifies a naming prefix for the output files as follows:

```
<output_file_prefix>.v
<output_file_prefix>.dofile
<output_file_prefix>.testproc
<output_file_prefix>.atpglib
```

By default, “test” is used for the naming prefix.

- *-simulation_library*
An optional switch that creates a Verilog simulation library from the specified cell library.
- *-design_interface filename*
An optional switch and string pair that specifies the pathname of the file containing a Verilog description of the design interface. The Verilog description file is used when the TestKompress logic is placed externally to the design core.

create_skeleton_design

- `-module_name` *module_name*

An optional switch and string pair that specifies the name of the generated skeleton design module. When this switch is not specified, the default module name is “`skeleton_design_top`”.

This switch is useful when a design created using the skeleton flow contains multiple EDT blocks. Normally, this would result in all of the EDT blocks having the same name, `skeleton_design_top_edt`. You can use this switch during the skeleton design generation step to provide different names for different EDT blocks.

- `-help`

An optional switch that lists all the invocation switches.

- `-verbose`

An optional switch that, together with `-help`, lists all the invocation switches and a brief description of each.

stil2mgc

A utility that converts STIL files to dofiles and test procedure files for Tessent FastScan and Tessent TestKompress. The converted files define clocks, scan chains, scan groups, and pin constraints. It also converts CTL files to the Tessent Core Description (TCD) format used by Tessent Scan. Another usage is for converting memory CTL descriptions to the TCD format used by Tessent MemoryBIST.

Usage

Usage 1

```
stil2mgc {-STil stil_filename [-TPf tpf_filename] [-DOfile dofile_name]
  [-FLex_dofile dofile_name]
  [-ALias Min | All] [-CApture NOne | Single | NAMED]
  [-EDGE_strobe_processing ON | OFF]
  [-INFer_pulse_clock ON | OFF]
  [-EXec exec_name]
  [-WRITE_CORE_DESCription
    [-OUTPUT_DIRectory dir_path]
    [-TCD_SCAN_EXTension ext]
    [-CTL_mode mode_name]
    [-CORE_name name]
  ]
  [-LOgfile logfile_name [-REplace]]} |
  [-help | -Usage | -MANual | -Version]
  [-Verbose]
```

Usage 2: Memory CTL to TCD Format Conversion

```
stil2mgc {-STil stil_filename
  [-WRITE_CORE_DESCription
    [-OUTPUT_DIRectory dir_path]
    [-TCD_MEMORY_EXTension ext]
    [-TCD_SCAN_EXTension ext]
    [(-ENVIRONMENT_name | -CORE_name) name]
    [-CTL_mode mode_name]
    [-TCD_NAME_OVERRIDE name]
    [-TCD_MEMORY_OVERRIDE overrides]
  ]
  [-LOgfile logfile_name [-REplace]]} |
  [-help | -Usage | -MANual | -Version]
  [-Verbose]
```

Description

Usage 1

For Tessent FastScan and Tessent TestKompress, invokes `stil2mgc` and produces a dofile that defines clocks, scan chains, scan groups, and pin constraints. This tool also creates test procedure files with a timeplate and the standard `test_setup`, `load_unload`, and `shift scan` procedures.

This command translates STIL signal groups, which are used in timeplates or procedures, into “alias” statements in the test procedure file. It also produces a test procedure file timeplate definition for each `WaveformTable` in the STIL file, exactly matching the timing specified in the STIL file.

Any procedure or macro with a name that matches a Tessent procedure type (`load_unload`, `master_observe`) is translated into that procedure. Any procedure or macro in the STIL file that has “capture” in its name is translated into a named capture procedure when you use the “-capture named” switch.

Any other macro whose name does not match anything that Tessent uses is translated into an unused sub-procedure.

For Tessent Scan, invokes `stil2mgc` to generate a Tessent Core Description (TCD) file with a populated Scan wrapper when you use the `-write_core_description` switch. This TCD file, also known as `tcd_scan`, enables stitching of scan segments defined in the input CTL file.

For more information about translation details, refer to “[Notes About Using the stil2mgc Tool](#)” in the *Tessent Shell User’s Manual*.

Note

 Refer to the [Core/Scan](#) page for details of the generated `tcd_scan` file. IEEE 1450.6 (CTL) describes how to define “DataType Constant” pins. The generated `tcd_scan` file represents these pins with a `TestEn` wrapper.

If the CTL description specifies “`InputProperty SynchLatch/SynchFF`” for the “`DataType ScanDataIn`” signal or “`OutputProperty SynchLatch/SynchFF`” for the “`DataType ScanDataOut`” signal, the polarity of `scan_in_clock` and `scan_out_clock` is inverted with respect to the one recovered from the `ScanMasterClock`, `CaptureClock`, and `LaunchClock` statements in the CTL description.

Usage 2

Invokes the `stil2mgc` utility and converts a memory CTL description to the Tessent Core Description (TCD) format used by Tessent MemoryBIST. The IEEE 1450.6.2 Standard for Memory Modeling in Core Test Language (memory CTL) is an extension of the IEEE 1450.6 Core Test Language (CTL) that can be used to describe the test and repair related aspects of memories. The `stil2mgc` utility options described in Usage 2 are used to process the memory

CTL description and to write out the equivalent memory TCD format in preparation for MemoryBIST insertion.

Arguments

- **-STil *stil_filename***

A required switch and string pair that specifies the name of the input STIL file. The supplied STIL file may be a STIL Procedure File (SPF) or a Core Test Language (CTL) file.
- **-TPf *tpf_filename***

An optional switch and string pair that specifies the name of the test procedure file to generate. If not specified, the *tpf_filename* is named by appending “.proc” to the STIL Test Procedure filename.
- **-DOfile *dofile_name***

An optional switch and string pair that specifies the name of the dofile to generate. If not specified, the *dofile_name* is named by appending “.dof” to the STIL Test Procedure filename.
- **-FLex_ *dofile_name***

An optional switch and string pair that produces an additional dofile targeted at the FlexTest tool.
- **-ALias Min | All**

An optional switch and literal pair that produces the minimum required alias statements in the MGC Procedure file or to produce alias statements for all signal groups found in the STIL Test Procedure file. The default is to produce the minimum required alias statements.
- **-CApture NOne | Single | NAMED**

An optional switch and literal pair that adds information to the MGC Procedure file. This switch either produces no capture procedures, a single default capture procedure, or multiple named capture procedures for each capture Macro found in the STIL Test Procedure File. The default is to produce no capture procedures.
- **-EDGe_ *strobe_processing* OFF | ON**

An optional switch and literal pair that specifies the type of strobe processing, edge strobe or window strobe, used to measure events.

ON

When you specify ON, the tool processes H and L waveform events in the SPF file to indicate edge strobe timing.

OFF

When you specify OFF, edge strobe timing is not created. This is the default
- **-INFer_pulse_clock ON | OFF**

An optional switch and literal pair to specify that stil2mgc uses the generic pulse_clock statement for clocks whose timing edges are identical.

ON

When you specify ON and the timing edges for all of the clock edges in the SPF file are identical, the produced timeplates uses the `pulse_clock` statement. If the timing edges are not identical for each clock, the produced timeplate uses individual pulse statements. This is the default

Off

When you specify Off, individual pulse clock statements are used for each clock.

- **-EXec *exec_name***

An optional switch and string pair to specify the name of the STIL PatternExec used when the STIL file has more than one PatternExec block. An error is reported when this switch is missing and more than one PatternExec blocks exist in the STIL file.

- **-WRITE_CORE_DESCRIPTion [-OUTPUT_DIRECTORY *dir_path*] [-TCD_SCAN_EXTENSION *ext*] [-CTL_mode *mode_name*] [(-ENVIRONMENT_name | -CORE_name) *name*] [-TCD_MEMORY_EXTENSION *ext*] [] [-TCD_NAME_OVERRIDE *name*] [-TCD_MEMORY_OVERRIDE *overrides*]**

An optional switch and options that write sub-chain definitions into the `tcd_scan` file, and memory test and repair configurations into the `tcd_mem_lib` file. If you specify this switch but do not provide the CTL block in the input file, the tool issues an error. Choose any of the following options:

Note

Refer to Tessent Core Description/[Scan](#) for details of generated `tcd_scan` file.

IEEE1450.6 (CTL) allows you to define “DataType Constant” pins. They are represented using a TestEn wrapper in a generated `tcd_scan` file.

-OUTPUT_DIRECTORY *dir_path* — An optional switch and string pair that specifies the destination directory where the tool writes the TCD files. By default, the tool writes the generated TCD files to the current directory. If the specified directory path does not exist, then the tool creates the directory.

-TCD_MEMORY_EXTENSION *ext* — An optional switch and string pair that specifies the file extension of the generated memory TCD file. The default file extension is “`tcd_mem_lib`”. The output filename is created by appending the extension to the Environment block name.

-TCD_SCAN_EXTENSION *ext* — An optional switch and string pair that specifies the file extension of the generated scan TCD file. The default file extension is `tcd_scan`. The tool creates the output filename by appending the extension to a core name or Environment block name.

-CTL_mode *mode_name* — An optional switch and string pair that specifies the test mode name corresponding to the scan chain information that the tool reads for Usage 1. For Usage 2, This pair specifies the CTLMode block for translation. If there is more than one CTLMode block in the Environment block, this switch is required to select the desired CTLMode block.

- (`ENVIRONMENT_name` | `CORE_name`) *name* — An optional switch and string pair that specifies a core name or an Environment block from the available values for translation. If there is more than one Environment block in the input CTL file, this switch is required to select the desired Environment block.
- `TCD_NAME_OVERRIDE` *name* — An optional switch and string pair that is used to override the Environment name during the TCD file generation. The string value specified becomes the TCD core name and the TCD filename base.
- `TCD_MEMORY_OVERRIDE` *overrides* — An optional switch and list to specify certain top-level TCD memory properties during the TCD generation phase. The value of this switch must be a space-separated list of property names and values, in the form “*key1 value1 key2 value2...*”. The properties that can be overridden are:
 - `DataOutHoldWithInactiveReadEnable`
 - `MemoryHoldWithInactiveSelect`
 - `MilliWattsPerMegaHertz`
 - `RetentionTimeMax`
 - `PipelineDepth`
 - `MinHold`

The only properties overridden are those specified with this switch, unspecified properties are not modified. For more information on these properties, refer to the [Memory](#) TCD wrapper description in *Tessent MemoryBIST User's Manual for Use With Tessent Shell*.

- `-Logfile` *logfile_name*
An optional switch and string pair that specifies the name of the file to write all session information.
- `-REplace`
An optional switch that overwrites the `-Logfile` *logfile_name* if one by the same name already exists.
- `-help`
An optional switch that displays a message that contains all the stil2mgc switches and a brief description of each.
- `-Usage`
An optional switch that displays the usage syntax for the stil2mgc command.
- `-MANual`
An optional switch that opens the Tessent Documentation System.
- `-Version`
An optional switch that displays the version of the stil2mgc tool that you currently have available.

Examples

Example 1

The following example illustrates Usage 1 and runs the `stil2mgc` tool on `design.spf`.

```
stil2mgc -stil design.spf -tpf new_design.tpf \  
-dofile new_dofile.do
```

Example 2

The following example illustrates Usage 1 and demonstrates invoking the tool for single-mode output:

```
stil2mgc -stil ../data/multi_mode.ctl \  
-ctl_mode scan_mode \  
-write_core_description
```

In the example, the tool writes the tool-generated files to the current directory.

Example 3

This example illustrates Usage 1 and demonstrates multi-mode output invocation. In the example, the tool writes the generated file as `./outDir/block.tcd`. This file contains a description of all modes containing valid scan chain data.

```
stil2mgc -stil ../data/multi_mode.ctl \  
-output_directory ./outDir \  
-tcd_scan_extension tcd \  
-core_name block \  
-write_core_description
```

Example 4

The following example illustrates Usage 1 and sources Tessent Shell tool-generated files:

```
set_context dft -scan  
# (...) loading design  
set_design_sources -format tcd_scan -Y ./ -extensions tcd_scan
```

Example 5

The following examples demonstrate Usage 2 for converting a memory CTL description to a TCD format using various settings that direct file location and naming. For this example, the memory CTL description is in the file `SYNC_1R1W_16x8.ctl` and contains a single Environment block named `SYNC_1R1W_16x8`. Invoking `stil2mgc` as shown generates the `SYNC_1R1W_16x8.tcd_mem_lib` TCD file in the current directory:

```
stil2mgc -stil SYNC_1R1W_16x8.ctl \  
-write_core_description
```

If you want to direct the generated TCD file to a subdirectory named `libraries`, the following command option is added:

```
stil2mgc -stil SYNC_1R1W_16x8.ctl \  
-write_core_description \  
-output_directory libraries
```

The TCD file extension can be changed as needed. For this example, if the TCD file is to be written in the current directory with the filename *SYNC_1R1W_16x8.lib*, the following command is run:

```
stil2mgc -stil SYNC_1R1W_16x8.ct1 \  
        -write_core_description \  
        -tcd_memory_extension lib
```

The TCD file and module name can also be changed. For this example, to convert the content of the memory CTL file described above to a TCD file named *SRAM16.tcd_mem_lib* that contains a TCD module named SRAM16, the following command is run:

```
stil2mgc -stil SYNC_1R1W_16x8.ct1 \  
        -write_core_description \  
        -tcd_name_override SRAM16
```

Example 6

The following Usage 2 example demonstrates converting a specified memory CTL Environment block for TCD file conversion. Given a memory CTL description named *all_cores.ct1* that contains multiple Environment blocks, the following command converts the Environment block named SYNC_1R1W_16x8 to a TCD file:

```
stil2mgc -stil all_cores.ct1 \  
        -write_core_description \  
        -environment_name SYNC_1R1W_16x8
```

Example 7

This Usage 2 example demonstrates converting a certain CTLMode in the memory CTL file to a TCD file. For this example, the memory CTL description is in the file *SYNC_1R1W_16x8.ct1* and contains multiple CTLMode blocks within a single Environment block. To convert the CTLMode block named MBIST to the TCD file format, the following command is run:

```
stil2mgc -stil SYNC_1R1W_16x8.ct1 \  
        -write_core_description \  
        -ctl_mode MBIST
```

Example 8

This Usage 2 example demonstrates overriding top-level TCD properties in the TCD file conversion. For this example, the memory CTL description is in the file *SYNC_1R1W_16x8.ct1* and contains one Environment block named SYNC_1R1W_16x8. To convert the contents to a TCD file with PipelineDepth overridden to 2 and MinHold to 1.5, the following command is run:

```
stil2mgc -stil SYNC_1R1W_16x8.ct1 \  
        -write_core_description \  
        -tcd_memory_override "PipelineDepth 2 MinHold 1.5"
```

The PipelineDepth and MinHold properties default to 0 when they are unspecified.

tessent

Invokes a Tessent tool in a command line session.

Usage

```
tessent {-shell [options] | -diagserver [options] | -yieldinsight [options]  
        | -siliconinsight {-ate | -desktop} [option] | -visualizer [options]}  
        | [-help]  
        | [-manual]
```

Description

Invokes a Tessent tool in a command line session.

Arguments

- **-shell** *options*
A switch and options that invokes the Tessent Shell. See “[tessent -shell](#)” on page 86.
- **-diagserver** *options*
A switch and options that invokes the Tessent Diagnosis server. See “[tessent -diagserver](#)” on page 83.
- **-yieldinsight** *options*
A switch and options that invokes Tessent YieldInsight. See “[tessent -yieldinsight](#)” on page 93.
- **-siliconinsight -ate | -desktop** *option*
A switch and literal pair that invokes Tessent SiliconInsight. See “[tessent -siliconinsight](#)” on page 90.
- **-visualizer** *options*
A switch and options that invokes Tessent Visualizer. See “[tessent -visualizer](#)” on page 91.
- **-help**
An optional switch that lists the switches for the tessent command.
- **-manual**
An optional switch that opens the Tessent Documentation System.

tessent -diagserver

Invokes the Tessent Diagnosis server.

Usage

```
tessent -DIAGSERVER
  [-daemon [daemon_id]]
  [-dlist]
  [{-dstatus | -dexit | -dterminate} daemon_id]
  [-HDB history_db]
  [-DOFile dofile_name... [-HIStory]]
  [-LOGfile logfile_name [-REPlace]]
  [-Arguments name=value ...]
  [-license_wait minutes | none | unlimited]
  [-HELP] | [-USAGE] | [-MANUAL] | [-VERSION]
```

Description

Invokes the Tessent Diagnosis server. See “[Running Tessent Diagnosis Server](#)” in the *Tessent Diagnosis User’s Manual*.

Arguments

- **-DIAGSERVER**
A required switch that invokes the Tessent Diagnosis server.
- **-daemon** [*daemon_id*]
An optional switch that invokes the Tessent Diagnosis server in daemon mode. The tool automatically assigns a process ID. Using the optional *daemon_id*, you can specify a process ID for the daemon.
- **-dlist**
An optional switch that lists running daemons, including the id, host, and logfile for each daemon.
- **-dstatus** *daemon_id*
An optional switch and integer pair that queries the status of a daemon you identify with *daemon_id* and displays the status of the monitors and analyzers.
- **-dexit** *daemon_id*
An optional switch and integer pair that instructs the daemon to exit after the tool finishes running any diagnosis jobs.
- **-dterminate** *daemon_id*
An optional switch and integer pair that instructs the daemon to immediately exit without finishing running any diagnosis jobs.

- **-HDB *history_db***

An optional switch and string that specifies the name of the History Database (HDB). The HDB is an SQL database containing information in tables. See “[History Database Schema](#)” in the *Tessent Diagnosis User’s Manual*.
- **-DOFile *dofile_name...* [-HIStory]**

An optional switch and repeatable string pair that specifies the name of one or more dofiles to run upon invocation. As the tool is processing each dofile, the Tcl variable “tessent_user_argv0” is assigned the name of the current dofile. -HIStory is an optional switch that adds dofile commands to the command line history list. The tool ignores the -History switch if you issue it without the -Dofile switch.
- **-LOGfile *logfile_name* [-REPlace]**

An optional switch and string pair that specifies the name of the file that you want Tessent Diagnosis to write all session information to. The default is to display session information to the standard output. The version banner that indicates the tool, version, date, and platform on which the log file was produced is included at the beginning of the file.

An optional -REPlace switch overwrites the *logfile_name* if a log file of the same name already exists.
- **-Arguments *name=value ...***

An optional switch and repeatable name/value pair that specifies variable names and values in a list named “tessent_user_arg.” No spaces are permitted between the name, the equal sign, and the value. This list can later be accessed by a dofile for the purpose of controlling parameters in the dofile. For more information, refer to “[Example 2](#)” on page 87.
- **-LICense_wait *minutes* | none | unlimited**

An optional switch and integer, or switch and literal, that specifies the tool’s response if the license is unavailable.

Choose one of the following options:

 - *minutes* — A positive integer that specifies the number of minutes to wait for the license.
 - none — A literal that directs the Tessent tool to exit immediately if no license is available.
 - unlimited — A literal that directs the Tessent tool to wait with no time limit for a license. This is the default.
- **-HELP**

An optional switch that lists the switches for the tessent command.
- **-USAGE**

An optional switch that lists the switches for the tessent command.

- **-MANUAL**
An optional switch that opens the Tessent Documentation System.
- **-VERSION**
An optional switch that displays the version of the tessent tool you specify.

Examples

See “[Introduction to Tessent Diagnosis Server](#)” in the *Tessent Diagnosis User’s Manual*

tessent -shell

Invokes a Tessent Shell environment.

Usage

```
tessent -Shell
  [-LOGfile logfile_name [-REPlace]]
  [-DOFile dofile_name]
  [-ARGuments {name=value}]
  [-LICENSE_WAIT {minutes | none | unlimited}]
  [-IGNORE_STARTUP_FILE]
  | [-HELP] | [-USAGE] | [-MANUAL] | [-VERSION]
```

Description

Invokes a Tessent Shell command line environment.

Arguments

- **-Shell**
A switch for invoking the Tessent Shell command line environment. For more information, refer to the “[Tessent Shell Introduction](#)” in the *Tessent Shell User’s Manual*.
- **-LOGfile *logfile_name* -REPlace**
An optional switch and string pair that specifies the name of the file to which you want Tessent Shell to write all session information. The default is to display session information to the standard output. The version banner that indicates the tool, version, date, and platform on which the log file was produced is included at the beginning of the file.
The optional **-REPLace** switch overwrites the *logfile_name* if a log file of the same name already exists.
- **-DOFile *dofile_name***
An optional switch and repeatable string pair that specifies the name of one or more dofiles to run upon invocation. As the tool is processing each dofile, the Tcl variable “`tessent_user_argv0`” is assigned the name of the current dofile.
- **-ARGuments *name=value***
An optional switch and repeatable name/value pair that specifies variable names and values in a list named “`tessent_user_arg.`” No spaces are permitted between the name, the equal sign, and the value. This list can later be accessed by a dofile for the purpose of controlling parameters in the dofile. For more information, refer to “[Example 2](#)” on page 87.
- **-LICENSE_WAIT *minutes* | none | unlimited**
An optional switch and integer, or switch and literal, that specifies the tool’s response if the license is unavailable.

Choose one of the following options:

- *minutes* — A positive integer that specifies the number of minutes to wait for the license.
 - *none* — A literal that directs the Tessent tool to exit immediately if no license is available.
 - unlimited — A literal that directs the Tessent tool to wait with no time limit for a license. This is the default.
- **-HELP**
An optional switch that lists the switches for the tessent command.
 - **-USAGE**
An optional switch that lists the switches for the tessent command.
 - **-MANUAL**
An optional switch that opens the Tessent Documentation System.
 - **-VERSION**
An optional switch that displays the version of the tessent tool you specify.

Examples

Example 1

The following example invokes Tessent Shell, uses the logfile *myLogfile* replacing any existing logfile with the same name, and runs the dofile *myDofile*.

```
tessent -shell -logfile myLogfile -replace -dofile myDofile
```

Example 2

The following example invokes Tessent Shell and runs a dofile named *dofile2*. The command line also specifies three variable/value pairs that are placed in a Tcl list named “tessent_value_arg” and thus made available to the dofile. It shows how to use single and double quotation marks to set variables that contains spaces. The system shell does not perform the expansion environment variable of the text surrounded by single quotes thus preserving the \$, unlike the text in quotation marks:

```
% setenv l2 3  
% tessent -shell -dofile dofile2 -arguments depths="9 \  
$l2" comment='Cost $US' output_dir=myOutDir
```

The following is the listing of *dofile2*, which demonstrates how to use the `-arguments` switch to set the values of variables inside the dofile. This technique enables you to reuse dofiles without modification:

```
# dofile2
# Set the default values of the control parameters
array set params {
    depths {}
    comment ""
    output_dir "outDir"
}
array set params $tessent_user_arg
# Use some params
puts "comment = $params(comment) "
if { [llength $params(depths)] > 0 } {
    # do whatever needs to be done in this case
    puts "depth list = $params(depths) " }
if { ![file isdirectory $params(output_dir)] } {
    puts "Creation of directory $params(output_dir) "
    file mkdir $params(output_dir) }
```

Here is the transcript produced by the invocation of Tessent Shell.

```
% setenv I2 3
% tessent -shell -dofile dofile2 -arguments depths="9 $I2" \
    comment='Cost $US' output_dir=myOutDir

//                                     ... Tool Banner ...
//
// command: # dofile2
// command: # Set the default values of the control parameters
// command: array set params {
//             depths {}
//             comment ""
//             output_dir "outDir"
//         }
// command: array set params $tessent_user_arg
// command: # Use some params
// command: puts "comment = $params(comment) "
//             comment = Cost $US
// command: if { [llength $params(depths)] > 0 } {
//             # do whatever needs to be done in this case
//             puts "depth list = $params(depths) "
//         }
//             depth list = 9 3
// command: if { ![file isdirectory $params(output_dir)] } {
//             puts "Creation of directory $params(output_dir) "
//             file mkdir $params(output_dir)
//         }
//             Creation of directory myOutDir
```

Example 3

The following example shows how to create a single shell script that invokes and passes arguments to Tessent Shell, which then runs the commands in the shell script as a regular dofile. In order for the following to work, the shell script file must have executable permissions.

The contents of the shell script, called *tScript* in this example, are as follows.

```
#!/bin/sh
#\
exec tessent -shell -dofile "$0" -arguments ${1+"$@"}

set_transcript_style off
puts "$tessent_user_arg"
# add dofile commands here
exit
```

The Linux shell interprets the second line (`#\`) as a comment and then runs the third line, which invokes Tessent Shell and passes the entire shell script as a dofile. (Tessent Shell tool's Tcl interpreter ignores the second and third lines of the shell script and then interprets all following lines as normal Tessent Shell commands.)

The `-arguments` switch on the third line enables you to pass an arbitrary number of argument/value pairs from the shell script invocation into a standard Tcl list called `"tessent_user_arg"` for later parsing and use by Tessent Shell. So, for example, when you invoke the shell script as follows:

```
% tScript myarg1=myvalue1 myarg2= myarg3=myvalue3
```

The three arguments and their values are passed to Tessent Shell, and the relevant part of the transcript would appear as follows:

```
// command: #!/bin/sh
// command: # exec tessent -shell -dofile "$0" -arg ${1+"$@"}
// command: set_transcript_style off
myarg1 myvalue1 myarg2 {} myarg3 myvalue3
```

tessent -siliconinsight

Invokes Tessent SiliconInsight.

Usage

```
tessent -siliconinsight {-ate | -desktop} [-help]
```

Description

Invokes Tessent SiliconInsight in either ATE or Desktop mode.

Depending on what you are using Tessent SiliconInsight for, refer to the following documentation:

- **LV Flow** — “[Invoking Tessent SiliconInsight](#)” in the *Tessent SiliconInsight User’s Manual for the LV Flow*.
- **Tessent Diagnosis** — “[Diagnosis for Tessent LogicBIST Designs](#)” in the *Tessent Diagnosis User’s Manual*.

Arguments

- **-siliconinsight -ate | -desktop**

A required switch and literal pair for invoking Tessent SiliconInsight. Choose from one of the following:

-ate — Invokes Tessent SiliconInsight ATE.

-desktop — Invokes Tessent SiliconInsight Desktop.

- **-help**

An optional switch that shows the manual pages for the tool.

tessent -visualizer

Invokes the Tessent Visualizer GUI.

Usage

```
tessent -visualizer
    [-help]
    [-version]
    [-logfile file]
    [-server hostname]
    [-tcp_port port]
    [-authorization_code code]
    [-label name]
    [-import_configuration filename]
```

Description

Invokes Tessent Visualizer.

See “[Tessent Visualizer](#)” in the *Tessent Shell User’s Manual*.

Arguments

- **-visualizer**
A required switch that invokes Tessent Visualizer.
- **-help**
An optional switch that displays a usage message for Tessent Visualizer. Tessent Visualizer is not started.
- **-version**
An optional switch that displays the Tessent Visualizer version. Tessent Visualizer is not started.
- **-logfile *file***
An optional switch and string pair that specifies the log filename.
- **-server *hostname* -tcp_port *port***
Optional switch and string pairs that specify the remote sever host name and TCP/IP port.
- **-authorization_code *code***
An optional switch and string pair that specifies a user-supplied six-digit client/server authorization code.
- **-label *name***
An optional switch and string pair that specifies a prefix to be added to the Tessent Visualizer window titles.

- `-import_configuration filename`

An optional switch and string pair that specifies a configuration file to be loaded during Tessent Visualizer startup. If the configuration file cannot be read, is invalid, or is from an incompatible version of Tessent Visualizer, an error message is displayed and Tessent Visualizer does not start.

See “[Saving and Restoring the Session State](#)” in the *Tessent Shell User’s Manual* for more information on using configuration files.

Examples

For specific examples, refer to “[Invoking Tessent Visualizer](#)” in the *Tessent Shell User’s Manual*.

tessent -yieldinsight

Invokes Tessent YieldInsight.

Usage

```
tessent -YIELDINSIGHT
  [-GUI]
  [-NOGUI]
  [-LOGfile logfile_name [-REPlace]]
  [-DOFile dofile_name]
  [-ARGuments {name=value}]
  [-LICENSE_WAIT {minutes | none | unlimited}]
  | [-HELP] | [-USAGE] | [-MANUAL] | [-VERSION]
```

Description

Invokes Tessent YieldInsight.

See the “[Overview of Tessent YieldInsight](#)” in the *Tessent YieldInsight User’s Manual* for complete information.

Arguments

- **-YIELDINSIGHT**
A required switch for invoking Tessent YieldInsight.
- **-GUI**
An optional switch for invoking the Tessent YieldInsight GUI. This is the default.
- **-NOGUI**
An optional switch for invoking the tool in command-line mode. By default, Tessent YieldInsight invokes in GUI mode.
- **-LOGfile *logfile_name* -REPlace**
An optional switch and string pair that specifies the name of the file to which you want Tessent Shell to write all session information. The default is to display session information to the standard output. The version banner that indicates the tool, version, date, and platform on which the log file was produced is included at the beginning of the file.
The optional **-REPLace** switch overwrites the *logfile_name* if a log file of the same name already exists.
- **-DOFile *dofile_name***
An optional switch and repeatable string pair that specifies the name of one or more dofiles to run upon invocation. As the tool is processing each dofile, the Tcl variable “tessent_user_argv0” is assigned the name of the current dofile.

- **-ARGUMENTS** *name=value*

An optional switch and repeatable name/value pair that specifies variable names and values in a list named “tessent_user_arg.” No spaces are permitted between the name, the equal sign, and the value. This list can later be accessed by a dofile for the purpose of controlling parameters in the dofile. For more information, refer to “[Example 2](#)” on page 87.

- **-LICENSE_WAIT** *minutes* | none | unlimited

An optional switch and integer, or switch and literal, that specifies the tool’s response if the license is unavailable.

Choose one of the following options:

- *minutes* — A positive integer that specifies the number of minutes to wait for the license.
- none — A literal that directs the Tessent tool to exit immediately if no license is available.
- unlimited — A literal that directs the Tessent tool to wait with no time limit for a license. This is the default.

- **-HELP**

An optional switch that lists the switches for the Tessent command.

- **-USAGE**

An optional switch that lists the switches for the Tessent command.

- **-MANUAL**

An optional switch that opens the Tessent Documentation System.

- **-VERSION**

An optional switch that displays the version of the Tessent tool you specify.

Chapter 3

Command Dictionary (A - D)

The Command Dictionary describes the application commands for Tessent Shell. For quick reference, the commands appear alphabetically with each beginning on a separate page.

The command usage line syntax conventions are common to all products documented in this manual.

Table 3-1. Conventions for Command Line Syntax

Convention	Example	Usage
UPPerCase	-Static	Required argument letters are in uppercase; in most cases, you may omit lowercase letters when entering literal arguments, and you need not enter in uppercase. Arguments are normally case insensitive.
Boldface	set_your_mode mode1 mode2	A boldface font indicates a required argument.
[]	exit [-force]	Square brackets enclose optional arguments. Do not enter the brackets.
<i>Italic</i>	dofile <i>filename</i>	An italic font indicates a user-supplied argument.
{ }	add_your_paths { <i>path_name</i> -All} [-max_paths <i>number</i>]	Braces enclose arguments to show grouping. Do not enter the braces.
	add_your_paths { <i>path_name</i> -All} [-max_paths <i>number</i>]	The vertical bar indicates an either/or choice between items. Do not include the bar in the command.
Underline	set_your_switch <u>ON</u> OFF	An underlined item indicates either the default argument or the default value of an argument.
...	add_your_clock <i>off_state</i> <i>pin_list</i> ...	An ellipsis follows an argument that may appear more than once. Do not include the ellipsis when entering commands.

Command Descriptions

This section describes commands, alphabetically from A through D, that available in Tessent Shell. The beginning of each command description shows the contexts and modes that support the command and provides the following information:

Context: Lists each context and sub-context that supports the command. “All contexts” means that the command is supported in all available contexts. “Unspecified” means that you do not have to set a context to use the command.

Mode: Lists each mode that supports the command. “All modes” means that the command is supported in all available modes. In some cases, a particular mode supports the command only within certain contexts, and this is noted in parentheses after the mode type.

Table 3-2. Commands A Through D

Command	Description
add_atpg_constraints	Restricts all patterns placed into the internal pattern set according to the user-defined constraints.
add_atpg_functions	Creates an ATPG function that you can then use when generating user-defined ATPG constraints.
add_bist_capture_range	Associates a named ATPG capture procedure with a subset of the BIST patterns.
add_black_boxes	Defines instances of Verilog modules or cell library models as black boxes and sets the constrained value on output or bidirectional black box pins.
add_cdp_test	Creates a new test in the CDP.
add_cell_constraints	Constrains scan cells (also non-scan cells for CX, TX, DX, and SX constraints) to a constant value.
add_cell_models	Specifies DFT library models for user-defined test points, system-generated test points, and system-generated test logic.
add_chain_masks	Masks the load, capture, and unload values on the specified scan chains during simulation.
add_clocks	Adds scan or non-scan clocks to the clock list for proper scan operation.
add_config_element	Adds a configuration element in the configuration data.
add_config_message	Adds error, warning, or information messages to configuration elements.
add_config_tab	Adds one configuration tree tab to the Configuration Data Visualizer window.

Table 3-2. Commands A Through D (cont.)

Command	Description
add_control_points	Specifies user-defined control points during test point insertion.
add_core_instances	Adds a core instance to the design by associating the core description currently in memory with the specified core instance(s) in the design.
add_dft_clock_enables	Defines a pin or port of the current design or a port of a sub-module as a clock enable signal that, when activated, turns off the clock gating on a clock branch.
add_dft_clock_mux	Instructs the tool to assume the presence of a clock multiplexer during pre-DFT DRC and to insert the multiplexer during DFT insertion as part of the <code>process_dft_specification</code> command.
add_dft_control_points	Instructs the tool to assume the presence of the DFT control logic during pre-DFT design rule checking, and to insert the controlling logic during DFT insertion as part of the <code>process_dft_specification</code> command.
add_dft_modal_connections	A command used to insert modal connections from specified output data source nodes or to input data destination nodes typically used to connect the EDT channel input and output pins from multiple cores to and from a limited set of input and output ports.
add_dft_signals	Adds static and dynamic DFT signals used to control various aspect of the DFT logic.
add_drc_violation	Adds a DRC violation to the list of DRC violations for a given DRC rule.
add_edt_blocks	Creates an arbitrary identifier for an EDT block and applies certain subsequent commands only to that block.
add_edt_configurations	Sets up EDT logic with two compression configurations.
add_false_paths	Defines false paths in the design. False paths are paths that cannot be activated in the design's functional (at-speed) mode of operation. You would typically determine them as a part of static timing analysis, prior to ATPG.
add_fault_sites	Automatically adds fault site definitions for library cells that do not have UDFM definitions.
add_faults	Adds faults to the current fault list, discards all patterns in the current test pattern set, and sets all faults to undetected.
add_gate_to_rtl_mapping	Adds rules for post-synthesis/post-layout to RTL instance name-mapping for DEF files.

Table 3-2. Commands A Through D (cont.)

Command	Description
add_icl_ports	Specifies top design ports that are added in the ICL file generated during ICL extraction.
add_icl_scan_interfaces	Adds the specified scan interfaces to the new ICL top module that is created during ICL extraction.
add_icl_ssn_datapaths	Specifies the SSN datapath identifiers that Tessent Shell will associate with certain ICL ports of the new ICL top module during ICL Extraction.
add_iddq_exceptions	Enables you to specify individual sites where the tool does not apply the Iddq restrictions.
add_ijtag_logical_connection	Creates a new logical connection path through the current design by specifying the source and destination of the logical path.
add_input_constraints	Constrains primary inputs to specified values.
add_layout_core_information	In hierarchical layout-aware diagnosis, adds core instance information to an existing core-level LDB.
add_lfsr_connections	Connects an external pin or an internal pin to a Linear Feedback Shift Register (LFSR).
add_lfsr_taps	Adds the tap configuration to a Linear Feedback Shift Register (LFSR) or a PRPG of type cellular automata (CA).
add_lfsrs	Adds LFSRs for use as PRPGs or MISRs.
add_lists	Adds pins to the list of pins on which to report.
add_loadboard_loopback_pairs	Creates a loopback connection from specified output ports to specified input ports.
add_misrs	Specifies the MISR structure and initial seed.
add_nofaults	Places nofault settings either on pin pathnames, pin names of specified instances, or modules.
add_nonscan_instances	Sets a user-specified is_non_scannable attribute on the specified design objects.
add_notest_points	Prevents test logic insertion in the specified regions.
add_observe_points	Specifies user-defined observe points during test point insertion.
add_output_masks	Ignores any fault effects that propagate to the primary output pins you name.
add_pattern_trigger	Adds a trigger for additional equipment for measurement at a specific pattern location. This command applies only to OpalKelly adapters using smart mode.

Table 3-2. Commands A Through D (cont.)

Command	Description
add_primary_inputs	Adds a primary input (PI) also known as an input pseudo_port to the specified pins or nets.
add_primary_outputs	Adds primary outputs (PO) to the specified net.
add_processors	Enables the tool to run multiple processors in parallel on multiple machines to reduce runtime.
add_read_controls	Specifies the off-state value for specified RAM read control lines.
add_register_value	Creates a static or dynamic variable through which you specify a register identifier, <i>value_name</i> , and, optionally, the state string, <i>value_string</i> .
add_rtl_to_gates_mapping	Adds name-mapping rules for RTL to post-synthesis/post-layout name mapping.
add_scan_chains	Specifies a name for a pre-existing scan chain within the design.
add_scan_groups	Specifies a group name for a set of pre-existing scan chains in a design.
add_scan_instances	Adds specified instances to the scannable instance list.
add_scan_mode	Specifies a chain scan mode, which defines one or more scan chains.
add_scan_segments	Adds one or more existing scan segment(s).
add_schematic_callout	Add an informational callout to a Tessent Visualizer schematic window.
add_schematic_connections	Displays design objects in the Tessent Visualizer schematic window and enables you to trace visually through the design.
add_schematic_objects	Displays provided objects in the specified Tessent Visualizer schematic window.
add_schematic_path	Display the specified path in one of the Tessent Visualizer schematic windows.
add_simdut_fault	Injects a stuck-at-0 fault or a stuck-at-1 fault into the specified signal for SimDUT simulation.
add_simulation_context	Creates a new user-defined simulation context.
add_simulation_forces	Forces one or more <i>gate_pin</i> objects to the specified value(s).
add_synchronous_clock_group	Defines a set of clocks that are synchronous (compatible) with each other.
add_tied_signals	Adds a value to floating signals or pins.

Table 3-2. Commands A Through D (cont.)

Command	Description
add_to_collection	Adds objects to a base collection and returns the new collection without affecting the original base collection.
add_wave_generator_pins	Displays provided pin objects in the Tessent Visualizer Wave Generator tab.
add_write_controls	Specifies the off-state value for specified RAM write control lines.
analyze_atpg_constraints	Checks the ATPG constraints you created for their satisfiability or mutual exclusivity.
analyze_bus	Analyzes the specified bus gates for contention problems.
analyze_compression	Analyzes the compression for an application in two steps.
analyze_control_signals	Identifies and optionally defines the primary inputs of control signals.
analyze_drc_violation	Generates a schematic in the schematic windows of the portion of the design involved with the specified rule violation number.
analyze_fault	Performs an analysis to identify why a fault is not detected and optionally displays the relevant circuitry in Tessent Visualizer.
analyze_graybox	Identifies the instances and nets to be included in the graybox netlist by automatically setting their <code>in_graybox</code> attributes to true. Subsequently, a “ <code>write_design -graybox</code> ” command writes out the graybox netlist for the marked instances and nets.
analyze_icl_suspect	Context: <code>patterns -silicon_insight -ijtag</code>
analyze_layout_hierarchy	Analyzes the layout LEF/DEF hierarchy and stores the analysis results in a layout hierarchy database.
analyze_restrictions	Performs an analysis to automatically determine sources of the problem from a failed ATPG run.
analyze_scan_chains	Distributes scan elements into new scan chains.
analyze_simulation_mismatches	Analyzes simulation mismatches that occur between test patterns and a simulation performed by a specified external timing simulator.
analyze_test_points	Specifies the test points analysis and generates a list of test points to be inserted by the tool.
analyze_wrapper_cells	Identifies shared and dedicated wrapper cells for the primary I/O ports.

Table 3-2. Commands A Through D (cont.)

Command	Description
<code>analyze_xbounding</code>	Performs X-bounding analysis.
<code>annotate_diagnosis</code>	Adds DFM and RCD data, if available, to existing diagnosis reports.
<code>append_to_collection</code>	Adds one or more objects to a collection referenced by the specified <i>var_name</i> .
<code>apply_specification_defaults</code>	Automatically applies all defaults specified in the DefaultsSpecification/DftSpecification and DefaultsSpecification/PatternsSpecification wrappers to wrappers that were created manually.
<code>assert_icl_sib</code>	Context: patterns -silicon_insight -ijtag
<code>catch_output</code>	Runs the specified tool command line, and may be used to prevent command errors from aborting the enclosing dofile or Tcl proc.
<code>check_design_rules</code>	Transitions the tool from setup mode to analysis mode.
<code>check_synthesis</code>	Checks the status of synthesis that was previously launched by the run_synthesis command.
<code>check_testbench_simulations</code>	Checks the status of simulations that were previously launched by the run_testbench_simulations command.
<code>close_layout</code>	Closes the LDB. Any subsequent diagnosis you perform is non-layout aware.
<code>close_pattern_set</code>	Finalizes and closes the currently open pattern set.
<code>close_tsdb</code>	Makes the contents of a previously opened TSDB directory invisible to the tool.
<code>close_visualizer</code>	Saves display data and closes Tessent Visualizer.
<code>collect_cdp_test_failure_logs</code>	Saves failure logs for a CDP test to a directory.
<code>compare_collections</code>	Compares the contents of two collections.
<code>compress_layout</code>	Compresses a LDB.
<code>compress_patterns</code>	Compresses patterns in the current test pattern set.
<code>convert_design_path_format</code>	Converts a list of design paths to the specified dot or slash separator.
<code>copy_collection</code>	Duplicates the contents of an existing collection, resulting in a new collection. The base collection remains unchanged.

Table 3-2. Commands A Through D (cont.)

Command	Description
copy_module	Creates an exact copy of a design module and assigns it a new name so that it can then be used as part of a <code>create_instance</code> and <code>replace_instances</code> .
copy_simulation_context	Copies the simulation values and forces from one simulation context to another.
create_bisr_segment_order_file	Creates the <code>BisrSegmentOrderSpecification</code> configuration data wrapper and extracts the list and ordering of BISR chain segments.
create_capture_procedures	Creates named capture procedures based on clock sequences either derived from patterns or specified at the command line.
create_connections	Connects pin, net, or port objects.
create_custom_bisr_register	Creates a customized BISR register that is manually instantiated by the user in the functional design and is used to control functional logic.
create_dft_specification	Creates the <code>DftSpecification</code> (<i>design_name,id</i>) configuration wrapper and returns the newly created wrapper object so that it can be stored in a variable and used to customize the created specification.
create_diagnosis_patterns	Creates targeted patterns for logic failure or scan chain failure iterative diagnosis.
create_feature_statistics	Calculates the root cause deconvolution (RCD) constants from the LDB for RCD diagnosis and analysis.
create_flat_model	Creates a primitive gate simulation representation of the design. The command also flattens the hierarchy of the design so that the design can be viewed in the Tessent Visualizer Flat Schematic window.
create_icl_flush_pattern	Context: patterns -silicon_insight -ijtag
create_icl_setup_pattern	Context: patterns -silicon_insight -ijtag
create_icl_verification_patterns	Specifies the creation of a structural pattern to verify the proper operation of the IJTAG network.
create_initialization_patterns	Creates RAM initialization patterns and places them in the internal pattern set.
create_instance	Instantiates an instance of a module <code>mod_spec</code> inside a design module in the current design.
create_layout	Generates a diagnosis tool-compatible Layout Database directory (LDB) from LEF/DEF input files.

Table 3-2. Commands A Through D (cont.)

Command	Description
<code>create_module</code>	Creates a new design module with no ports.
<code>create_net</code>	Creates a net inside an instance of a design module in the current design.
<code>create_open_socket_failure</code>	Creates emulated open-socket failure files to use for validating reverse mapping top-level failures to the core in Tessent Diagnosis.
<code>create_patterns</code>	Performs automatic high-speed test generation and pattern compression.
<code>create_patterns_specification</code>	Generates a pattern specification for the specified usage. The usage is either signoff or manufacturing. The tool supports IJTAG and MemoryBIST patterns.
<code>create_pin</code>	Creates a pin on an instance of a design module.
<code>create_port</code>	Creates a port on the specified design module.
<code>create_reversible_patterns</code>	Generates reversible test patterns.
<code>create_scan_chain_family</code>	Creates a scan_chain_family object, which controls how one or more scan chains are allocated/connected during distribution.
<code>create_scan_segment</code>	Creates a spec scan segment that enables you to force sequences of scan elements to be stitched together within scan chains.
<code>create_silicon_insight_setup_specification</code>	Generates a default Tessent SiliconInsight setup specification.
<code>create_ssn_continuity_patterns</code>	Creates an SSN continuity pattern to test the internal path of the ScanHost from input to output.
<code>deassert_icl_sib</code>	Context: patterns -silicon_insight -ijtag
<code>defer_schematic_updates</code>	Postpones schematic updates until after the scope introduced by the command ends.
<code>delete_atpg_constraints</code>	Removes state restrictions from the specified pins.
<code>delete_atpg_functions</code>	Removes the specified function definitions.
<code>delete_bist_capture_ranges</code>	Specifies that the tool no longer uses a particular named capture procedure when generating BIST patterns.
<code>delete_black_boxes</code>	Undoes the effect of the add_black_boxes command.
<code>delete_capture_procedures</code>	Removes the specified capture procedures from internal memory.
<code>delete_cdp_test</code>	Removes the specified test from the CDP.

Table 3-2. Commands A Through D (cont.)

Command	Description
<code>delete_cell_constraints</code>	Removes constraints placed on scan cells.
<code>delete_cell_library</code>	Removes all current cell libraries, the current design including the flat model, and all tool data that is design-specific.
<code>delete_cell_models</code>	Specifies the name of the DFT library cell that the tool is to remove from the active list of cells that the user can access when adding test points or that the tool can access when inserting test logic.
<code>delete_chain_masks</code>	Removes chain masks from the specified scan chains.
<code>delete_clocks</code>	Removes clocks from the clock list.
<code>delete_config_element</code>	Deletes one or more configuration elements. Only elements that can be added can be deleted.
<code>delete_config_messages</code>	Deletes error, warning or info message that were added to configuration elements using the <code>add_config_message</code> command.
<code>delete_config_tabs</code>	Deletes one or many configuration tree tabs from the Configuration Data Visualizer window that was previously added using the <code>add_config_tab</code> or <code>display_specification</code> command.
<code>delete_connections</code>	Disconnects net, pin, or port objects.
<code>delete_core_descriptions</code>	Removes core descriptions that have been read in using the <code>read_core_descriptions</code> command from memory.
<code>delete_core_instances</code>	Removes an instance binding created with the <code>add_core_instances</code> command.
<code>delete_design</code>	Removes all design modules including the flat model and all tool data that is design-specific.
<code>delete_dfm</code>	Deletes a DFM rule from the open LDB.
<code>delete_dft_clock_enables</code>	Deletes one or all previously added DFT clock enable signals.
<code>delete_dft_clock_muxes</code>	Deletes one or all previously added DFT clock multiplexers.
<code>delete_dft_control_points</code>	Deletes one or all previously added DFT control points.
<code>delete_dft_modal_connections</code>	You use the <code>delete_dft_modal_connections</code> command to delete modal connection specifications previously added by the <code>add_dft_modal_connections</code> command.
<code>delete_dft_signals</code>	Deletes a DFT signal that was previously added using the <code>add_dft_signals</code> command.

Table 3-2. Commands A Through D (cont.)

Command	Description
<code>delete_edt_blocks</code>	Removes the data for the specified EDT block(s) from the tool's internal database.
<code>delete_edt_configurations</code>	Deletes specified compression configurations from all blocks in a design.
<code>delete_false_paths</code>	Removes definitions of false paths.
<code>delete_fault_sites</code>	Removes bridge entries, delay paths, user-defined fault sites, and any associated faults from the current fault list. For UDFMs, all faults are removed.
<code>delete_faults</code>	Removes faults from the current fault list.
<code>delete_flat_model</code>	Deletes a flat model that was previously created either by going to system mode analysis or by using the <code>create_flat_model</code> command.
<code>delete_gate_to_rtl_mapping</code>	Removes the specified rule for post-synthesis/post-layout to RTL instance name-mapping for DEF files.
<code>delete_icl_modules</code>	Deletes the specified ICL modules from memory.
<code>delete_icl_ports</code>	Undoes the effect of the <code>add_icl_ports</code> command on a specified list of top level ports.
<code>delete_icl_scan_interfaces</code>	Deletes the specified scan interfaces previously added by <code>add_icl_scan_interfaces</code> from the new ICL top module that is created during ICL extraction.
<code>delete_icl_ssn_datapaths</code>	Deletes the SSN datapath specifications added with the <code>add_icl_ssn_datapaths</code> and <code>set_icl_ssn_datapath_ports</code> commands.
<code>delete_iddq_exceptions</code>	Deletes exceptions to Iddq restrictions added with the <code>add_iddq_exceptions</code> command.
<code>delete_ijtag_logical_connection</code>	Removes logical connections previously added to a design. You must specify either the source pin/port or the destination pin/port or both source and destination pins/ports.
<code>delete_input_constraints</code>	Removes previously applied constraints from primary input pins.
<code>delete_instances</code>	Deletes the specified instance objects from the current design.
<code>delete_iprocs</code>	Deletes the specified list of iProcs attached to the ICL module specified by the last <code>iProcsForModule</code> command, or to the ICL module specified by <code>module_name</code> .

Table 3-2. Commands A Through D (cont.)

Command	Description
<code>delete_layout_core_information</code>	In hierarchical layout-aware diagnosis, deletes all core instance data or the core instance data from a specified design.
<code>delete_layout_verification</code>	Reports or deletes stored layout verification information from the current layout database.
<code>delete_lfsr_connections</code>	Removes connections between the specified primary pins and Linear Feedback Shift Registers (LFSRs).
<code>delete_lfsr_taps</code>	Removes the tap positions from a Linear Feedback Shift Register (LFSR).
<code>delete_lfsrs</code>	Removes the specified Linear Feedback Shift Registers (LFSRs).
<code>delete_lists</code>	Removes pins from the pin list the tool monitors and reports on during simulation.
<code>delete_loadboard_loopback_pairs</code>	Deletes any loopback connection associated with the specified ports.
<code>delete_misrs</code>	Deletes MISRs you specify with the <code>add_misrs</code> command.
<code>delete_multicycle_paths</code>	Removes definitions of multicycle paths previously read in using the <code>read_sdc</code> command.
<code>delete_nets</code>	Removes net objects inside an instance of a design module.
<code>delete_nofaults</code>	Removes the nofault settings from either the specified pin or instance/module pathnames.
<code>delete_nonscan_instances</code>	Resets any user-specified <code>is_non_scannable</code> attribute on the specified objects.
<code>delete_notest_points</code>	Enables test logic insertion in the specified regions.
<code>delete_output_masks</code>	Removes the masking of the specified primary output pins.
<code>delete_pattern_trigger</code>	Deletes pattern triggers set with the <code>add_pattern_trigger</code> command.
<code>delete_patterns</code>	Deletes the current pattern set.
<code>delete_pins</code>	Removes pin objects from a design module instance.
<code>delete_ports</code>	Removes port objects from a design module.
<code>delete_primary_inputs</code>	Removes the specified primary inputs from the existing flat model or, if a flat model does not yet exist, from the flattened result.

Table 3-2. Commands A Through D (cont.)

Command	Description
<code>delete_primary_outputs</code>	Removes the specified primary outputs from the existing flat model or, if a flat model does not yet exist, from the flattened result.
<code>delete_processors</code>	Removes processor definitions previously specified with the <code>add_processors</code> command.
<code>delete_read_controls</code>	Removes the read control line definitions from the specified primary input pins.
<code>delete_register_value</code>	Deletes all or a specified register value variable specified with the <code>add_register_value</code> command.
<code>delete_rtl_to_gates_mapping</code>	Removes name-mapping rules for RTL to post-synthesis/post-layout name mapping.
<code>delete_scan_chain_families</code>	Removes scan chain families.
<code>delete_scan_chains</code>	Removes the specified scan chain definitions from the scan chain list.
<code>delete_scan_elements</code>	Removes scan elements (such as chain or segment) of a given name.
<code>delete_scan_groups</code>	Removes the specified scan chain group definitions from the scan chain group list.
<code>delete_scan_instances</code>	Removes the specified, sequential instances from the user-identified scan instance list.
<code>delete_scan_modes</code>	Removes one or more scan modes.
<code>delete_schematic_callout</code>	Deletes informational callouts from a Tessent Visualizer schematic window.
<code>delete_schematic_objects</code>	Deletes design objects from a Tessent Visualizer schematic window.
<code>delete_schematic_path</code>	Delete the specified path from a Tessent Visualizer schematic window.
<code>delete_simdut_fault</code>	Removes the injected stuck-at fault at the specified signal or all the injected faults.
<code>delete_simulation_contexts</code>	Deletes one or more user-defined simulation contexts.
<code>delete_simulation_forces</code>	Removes forces from one or more <code>gate_pin</code> objects.
<code>delete_synchronous_clock_group</code>	Removes one or more user-defined synchronous clock groups.
<code>delete_test_points</code>	Removes the specified test point definitions.

Table 3-2. Commands A Through D (cont.)

Command	Description
delete_tied_signals	Removes the assigned (tied) value from the specified floating nets or pins.
delete_wave_generator_pins	Deletes provided pin objects, or all objects, from the Tessent Visualizer Wave Generator tab.
delete_write_controls	Removes the write control line definitions from the specified primary input pins.
diagnose_failures	Diagnoses the failures in the specified failure file.
display_diagnosis_report	Opens a diagnosis report in which you can click symptoms and suspect locations to add related gates to the Tessent Visualizer Hierarchical Schematic window.
display_message	Sends a message to the specified message stream.
display_specification	Displays the DftSpecification(<i>design_name,id</i>) configuration data in a tab of the Configuration Tree Visualizer window.
dofile	Runs the commands contained within the specified file.

add_atpg_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Restricts all patterns placed into the internal pattern set according to the user-defined constraints.

Usage

```
add_atpg_constraints {0 | 1 | Z} {pin_pathname | gate_id# | function_name |  
  {-Cell cell_name {pin_name...}}... [-Instance {object_expression...}]  
  [-MODULE {module_name ...}]... [-DYNAMIC | -STATIC]  
  [-NOclock_check | -Load_only]
```

Description

When a simulated pattern is rejected, a message is issued that indicates the number of rejected patterns and the first gate at which the failure occurred. You can control the severity of the violation with the [set_contention_check](#) command. If you set the checking severity to Error, the simulation is terminated if it rejects a pattern due to a user-defined constraint. You can analyze the simulation data up to the termination point by using the [report_gates](#) command with the Error_pattern option.

User-defined constraints are used when using Tessent FastScan or Tessent TestKompress to generate test patterns with deterministic test generation methods. When test patterns are generated randomly using Tessent FastScan or Tessent TestKompress, the use of the user-defined ATPG constraints is not ensured; however, non-conforming random patterns are rejected.

If you change an ATPG constraint for a single internal set of patterns, pattern compression continues using the new constraints, which can cause the good patterns to be rejected. Therefore, you should remove all ATPG constraints before compressing the pattern set.

Note

 If you constrain a pin by directly creating an ATPG constraint to the *pin_pathname*, and then create another constraint that indirectly creates a different constraint, the constraint that directly specified the *pin_pathname* (overriding the global ATPG cell constraint) is used.

The -Dynamic switch lets you change the ATPG constraints any time during the ATPG process, affecting only the fault simulation and capture that occurs after the constraint changes. Any subsequently simulated patterns that fail to meet the current constraints are rejected during fault simulation.

Dynamic ATPG constraints do not affect DRC because of their temporary nature. Static ATPG constraints are unchangeable in analysis mode, ensuring that DRC must be repeated if they are changed.

Arguments

- **0 |1 |Z**

A literal that restricts the named object to a low state, high state, or high impedance state, respectively. You must choose one of the three literals to indicate the state value to which you want the tool to constrain the specified object.

The following lists the four objects on which you can place the constraint. You can use any number of the four argument choices in any order.

- ***pin_pathname***

A repeatable string specifying the pathname of a top-level pin or a library model pin on which you are placing the constraint. Pathnames of pins on intermediate hierarchy modules are not supported.

- ***gate_id#***

A repeatable integer specifying the gate identification number of the gate you want to constrain.

- ***function_name***

A repeatable string specifying the name of a function you created with the [add_atpg_functions](#) command. If you place a constraint on an ATPG function that you generated with the `add_atpg_functions -Cell` command, all cells affected by that ATPG function are also constrained. You can delete all these constraints using the *function_name* argument with the `delete_atpg_constraints` command.

- ***-Cell cell_name {pin_name}***

A repeatable switch and string pair specifying the name of a DFT library cell and name of a pin on that cell. You can repeat the *pin_name* argument if there are multiple pins or nets on a cell that you need to constrain. If you use the `-Cell` option, an ATPG constraint is placed on every occurrence of that cell within the design.

- ***-Instance object_expression***

An optional switch and repeatable string pair that places ATPG constraints inside the specified list of instances. You can use regular expressions, which may include any number of embedded asterisk (*) and question mark (?) wildcard characters. You can only use this switch when using the `-Cell` switch or when a function name is specified.

- ***-MODULE module_name***

An optional switch and repeatable string pair that places the ATPG constraints inside all instances of the specified module.

- ***-DYNAMIC***

An optional switch that satisfies only the ATPG constraints during the ATPG process and not during DRC. You can change these constraints during the ATPG process; therefore, DRC does not check these constraints. This is the default.

- **-Static**
An optional switch that satisfies the ATPG constraints you are defining during all its processes. You can only add or delete static ATPG constraints when you are in Setup mode, ensuring the static ATPG constraints are used for all ATPG analyses during design rules checking. DRC checks for any violations of ATPG constraints during the simulation of the test procedures (rule E12).
- **-NOCapclock_check**
An optional switch that suppresses checking of specified ATPG constraints after the capture clock. By default, ATPG constraints are checked at the same time as bus contention. If contention checking is performed after the capture clock, ATPG constraints are also checked after the capture clock. You cannot use this switch and **-Load_only** at the same time.

In some situations, you may have some ATPG constraints that do not need to be checked after the capture clock; although, you may want other constraints and bus contention to be checked after the capture clock. In this case, you can use the **-Nocapclock_check** switch on certain constraints to suppress checking of those constraints after the capture clock.
- **-Load_only**
An optional switch specifying the Atpg constraint only applies to the first cycle after shift. When using Tessent FastScan or Tessent TestKompress, the values loaded into the scan chain and the forced PI values satisfy the constraint; however, once the leading edge of the first clock occurs, the constraint no longer applies (as if it were temporarily deleted until the next load, then re-added). Constraints added using the **-Load_only** option are satisfied by each scan load of a RAM sequential pattern and by each scan load of a clock sequential multiple load pattern. A clock sequential multiple load pattern occurs when you issue the **set_pattern_type** command with the **-Multiple_load** switch on, and the **-Sequential** switch set to 2 or more. Note that you cannot use the **-Load_only** and **-NOCapclock_check** switches at the same time.

Examples

Example 1

The following example creates a user-defined ATPG function and then uses it when creating ATPG pin constraints:

```
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q  
add_atpg_constraints 0 /i$135/q  
add_atpg_constraints 1 and_b_in
```

Example 2

The following example creates a user-defined ATPG function and then uses it when creating ATPG constraints. The ATPG constraints are added to the instances inside core1 only.

```
add_atpg_functions mux_1hotsel SELECT1 -cell imux3sux2 S2 S1 S0  
add_atpg_constraints 1 mux_1hotsel -instance core1
```

Example 3

The following example adds ATPG constraints to all occurrences of the specified cell inside the instances with pathnames that begin with “/core1/u19/reg”.

```
add_atpg_constraints 1 -cell imux3sux2 S1 -instance /core1/u19/reg*
```

Example 4

The following example shows how to use wildcards in the second level of hierarchy.

```
add_atpg_constraints 1 -cell imux3sux2 S1 -instance /core1/*/reg*
```

add_atpg_functions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Creates an ATPG function that you can then use when generating user-defined ATPG constraints.

Usage

```
add_atpg_functions function_name type {pin_pathname | gate_id# | existing_function_name  
| {-Cell cell_name {pin_name | -Function type pin_name...}...}}...
```

Description

You can specify any combination of pin pathnames, gate identification numbers, and previously user-defined functions. You can precede any object with the tilde (~) character to indicate an inverted input with respect to the function. If you specify an input pin pathname, the tool automatically converts it to the output pin of the gate that drives that input pin.

Arguments

- *function_name*

A required string that specifies the name of the ATPG function you are creating. You can use this *function_name* as an argument to the [add_atpg_constraints](#) command.

- *type*

A required argument specifying the operation that the function performs on the selected objects. The choices for the *type* argument, from which you can select only one, are as follows:

And — The output of the function is the same as for a standard AND gate.

Or — The output of the function is the same as for a standard OR gate.

Equiv — The output of the function is a high state (1) if all its inputs are at a low state (0), or if all its inputs are at a high state (1). So, the function's output is a low state if there is at least one input at a low state and at least one input at a high state.

Select — The output of the function is a high state (1) if all its inputs are at a low state (0) or if one input is at a high state and the other inputs are at a low state. So, if there are at least two inputs at a high state, the function's output is at a low state.

SELECT1 — The output of the function is a high state (1) if one input is at a high state and the other inputs are at a low state (0). So, the function's output is a low state if there are at least two inputs at a high state or all inputs are at a low state.

The following lists the objects on which the function operates. You can use any number of the argument choices in any order.

- ***pin_pathname***
A repeatable string that specifies the pathname to the pin on which you are placing the function. If you specify an input pin name, it is automatically replaced with the output pin of the gate that drives that input pin.
- ***gate_ID#***
A repeatable integer that specifies the gate identification number.
- ***existing_function_name***
A repeatable string that specifies the name of another function you created with the `add_atpg_functions` command. The *existing_function_name* argument cannot be the same as any pin name in the design. This string cannot be used with the `-Cell` option.
- **`-Cell cell_name {pin_name | -Function type pin_name}`**
A repeatable switch with a corresponding pair of strings that specify the name of a DFT library cell or pin on that cell. You can repeat the *pin_name* argument if you need to constrain multiple pins or nets on a cell.

The `-Function` switch is a repeatable switch with corresponding strings that specify the function type and a list of specific pins on cell *cell_name* that are arguments to the function. You can repeat the *pin_name* argument if you need to constrain multiple pins. This switch enables you to define a maximum of two layers of functions with the `-Cell` switch. Normally, you can define two functions, *f1* and *f2*, and then add a third function, *f3*, that refers to *f1* and *f2*. However, this is not permitted when you use the `-Cell` switch.

For information on how this switch is used, see [Example 2](#).

If you use the `-Cell` option, an ATPG function is placed on every occurrence of that cell within the design.

Examples

Example 1

The following example creates an ATPG function and then uses it in an `add_atpg_constraints` command:

```
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 1 and_b_in
```

Example 2

The following example generates multiple levels of ATPG functions when using the `-Cell` switch.

For every instantiation of the OR4 cell, the following function is implemented:

```
[ ( A AND B ) OR ( C OR D ) ]
```

where A, B, C, and D are inputs of the OR4 cell. Normally, you can define two functions, *f1* and *f2*, then add a third function, *f3*, that refers to *f1* and *f2*. However, when you use the `-Cell` switch

with the `add_atpg_functions` command, this is not possible. You can use the `-Function` switch to define up to two levels of functions using the `-Cell` switch. The syntax is as follows:

```
add_atpg_functions top_function or -cell OR4 -function and A B -function or C D
```

This implemented the previously mentioned function, which can be confirmed with the `report_atpg_functions` command.

Example 3

The following example assigns the two Q outputs of scan cells `/u11` and `/u12` to always have the same assigned state after loading.

```
add_atpg_functions CELL_INCLUSIVE equiv /u11/Q /u12/Q  
add_atpg_constraints 1 CELL_INCLUSIVE
```

Example 4

The following example causes one input to always be the opposite from the other. The tilde (`~`) character is the negation symbol.

```
add_atpg_functions CELL_EXCLUSIVE equiv ~ /u71/Q /u72/Q  
add_atpg_constraints 1 CELL_EXCLUSIVE
```

[report_atpg_functions](#)

add_bist_capture_range

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Associates a named ATPG capture procedure with a subset of the BIST patterns.

Usage

`add_bist_capture_range atpg_capture_proc_name start_value stop_value`

Description

Hybrid TK/LBIST Flow Usage

The `add_bist_capture_range` command is added once per NCP. Once all the NCPs are applied, the tool restarts from the first NCP.

Additionally, the command is automatically added to the logicBIST fault simulation dofile written out during IP generation. For usage information, refer to “[LogicBIST Fault Simulation and Pattern Creation](#)” in the *Hybrid TK/LBIST Flow User’s Manual*.

Arguments

- ***atpg_capture_proc_name***
A required string that specifies the name of the ATPG capture procedure.
- ***start_value***
A required argument that specifies the beginning of a contiguous range for a group of capture procedures. The tool typically generates the start and stop values in the BIST controller synthesis phase, and you should not change the values.
- ***stop_value***
A required argument that specifies the end of a contiguous range for a group of capture procedures. The tool typically generates the start and stop values in the BIST controller synthesis phase, and you should not change the values.

Examples

This example shows the association of NCPs with capture ranges corresponding to the specification - `clk1_twice 34 percent`, `clk2_twice 33 percent`, and `clk3_twice 33 percent`:

```
add_bist_capture_range clk1_twice 0 87
add_bist_capture_range clk2_twice 88 171
add_bist_capture_range clk3_twice 172 255
```

[set_lbist_controller_options](#)

add_black_boxes

Context: all contexts

Mode: setup

Defines instances of Verilog modules or cell library models as black boxes and sets the constrained value on output or bidirectional black box pins.

Usage

```
add_black_boxes {{{-Instances ins_pathnames | -Modules module_names}  
[0 | 1 | X | Z]} [-Pin pinname {0 | 1 | X | Z}]...} | {-Auto [0 | 1 | X | Z]}  
[-FAUlt_boundary | -NOFAUlt_boundary | -NO_Boundary]
```

Description

A blackbox is an instance that has no defined model or that you want to treat as though it has no model.

You can blackbox a single instance, or every instance of a particular module or cell library model that you do not want included in the netlist used by the tool. You can also use this command to automatically blackbox instances of nonexistent modules or cell library models.

When reading in a Verilog netlist, a warning message is issued when an instance is found that references a model (Verilog module or cell library model) that is not in the netlist or cell library. A referenced model for which a module or cell library model of the same name is not found in the netlist or cell library is considered to be undefined. You must blackbox instances of undefined models; otherwise, an error message is issued when you attempt to perform certain tasks such as leave Setup mode or enter a create_flat_model command. The message lists the names of referenced models that were not found in the netlist or cell library. You can also list the names using “report_black_boxes -undefined”.

Use add_black_boxes with the -Auto switch to automatically blackbox all instances of models that are considered to be undefined. By default, instances that are automatically blackboxed drive Xs on their outputs. Faults that propagate to the black box inputs are classified as ATPG_untestable (AU). You can use the add_black_boxes command to change the output values.

Issuing multiple add_black_boxes commands in succession, the first with the -Module switch and subsequent ones with -Instance, globally blackboxes all instances of a particular module or cell library model while selectively blackboxing particular instances of the same module or cell library model with slightly different pin values.

Tip

For optimal performance, issue all add_black_boxes commands after reading the design and library but before issuing any other commands.

In `dft -rtl` context only, the tool automatically blackboxes modules or instances detected as Synopsys DesignWare modules. The actual blackbox operation is done when the tool transitions from setup to analysis mode using the `set_system_mode` command. When the tool exits analysis mode, the tool automatically resets the black box definitions.

Arguments

- **-Instances** *ins_pathnames*

A switch and string pair that specifies to blackbox the objects specified by the *ins_pathnames* argument. The *ins_pathnames* argument can be a Tcl list of one or more instances or a collection of one or more instances.

Note

 Blackboxing implemented using the `-Instances` switch always overrides blackboxing implemented with the `-Modules` switch.

- **-Modules** *module_names*

A switch and string pair that specifies to blackbox every instance of the Verilog module or cell library model specified by the *module_names* argument. The *module_names* argument can be a Tcl list of one or more modules or a collection of one or more modules.

- **-Auto**

A switch that blackboxes any netlist instance that references a model (Verilog module or cell library model) that is not in the netlist or in the cell library.

Note

 To properly blackbox instances for Tessent FastScan MacroTest, use the `-Instance` or `-Module` switch. The `-Auto` switch is not intended for use with Tessent FastScan MacroTest. To ensure success, you must also define at least the module (or entity or cell library model) pins, including names, directions, and width of vectors.

Note

 To prevent unintentional black-boxing of new undefined modules in future executions of your scripts, it is recommended to not use the `-auto` switch in your dofile.

- **0 | 1 | X | Z**

An optional literal that specifies pin tie values. When used with the `-Instance` or `-Module` switch, it specifies the tie value for any pin not explicitly defined by the `-Pin` switch. When used with `-Auto`, it specifies the tie value for every pin. If you specify no value for this option, then the `set_tied_signals` command's value is the default.

- **-Pin *pinname*0 | 1 | X | Z**
An optional, repeatable switch, string, and literal that specifies the tie value of a particular pin. Use this switch to explicitly define the tie value for a pin, overriding for that pin the global tie value in effect for the **-Instance** or **-Module** switch.
- **-FAUlt_boundary**
A switch that keeps pin pathnames at the boundaries of all blackboxed instances and enables boundary pins to become fault sites. This is the default for ``celldefine` modules and library models.
- **-NOFAUlt_boundary**
A switch that keeps pin pathnames at the boundaries of all blackboxed instances, but does not permit boundary pins to become fault sites. This is the default for blackboxed instances that are not ``celldefine` modules or library models.
- **-NO_Boundary**
A switch that does not keep pin pathnames at the boundaries of all blackboxed instances and does not permit boundary pins to become fault sites.

Note

Do not include this switch when you use the `add_black_boxes` command to blackbox a macro for Tessent FastScan MacroTest. The Tessent FastScan `macrotest` command must be able to find pin pathnames at the macro boundary.

Examples

Example 1

The following example creates a black box for a module named “core,” with each output driven by a tie0 logic gate. The example then overrides, for the single instance “/core1” of the module “core,” the output value of pin1, so it is driven by a tie1 logic gate instead of a tie0. All other instances of the “core” module still have outputs driven by tie0 logic.

```
add_black_boxes -modules core 0
add_black_boxes -instances /core1 -pin pin1 1
```

Example 2

The following example shows the tool’s warning message for instances of undefined models. The example then creates black boxes for these instances.

```
// Warning: Undefined modules were found.
// Before using "set_system_mode" or "create_flat_model", you must either
// define the missing modules using "read_verilog" and/or
// "read_cell_library", or use the following command to treat them as
// black boxes:
// add_black_boxes -modules { \
//   and02 \
//   ao2 \
// }
// You can also use "add_black_boxes -auto" to black box all undefined
// modules but it is recommended that you do not add this command to your
// dofile. Doing so may unintentionally black-box new undefined modules
// in future runs.
```

add_black_boxes -auto**Example 3**

The following example shows two commands that keep the pin pathnames at the boundary of each instance of the blackboxed module named “macro1.” Either command enables Tessent FastScan MacroTest to function properly:

```
add_black_boxes -modules macro1 -fault_boundary
add_black_boxes -modules macro1 -nofault_boundary
```

Example 4

The following example creates blackboxes for the collection of modules returned by the `get_modules` command. The `get_modules` command returns only those modules that have been marked by the user with the user-defined attribute `mark_black_box`.

```
add_black_boxes -modules [get_modules -filter mark_black_box]
```

Example 5

Similar to Example 4, this example operates on instances that have a user-defined attribute `mark_black_box`.

```
add_black_boxes -instances [get_instances -filter mark_black_box]
```

Example 6

The following example creates blackboxes by assigning the collection of modules returned by the `get_modules` command to a variable. The `add_black_box` command then operates on the collection contained in the `to_black_box` variable.

```
set to_black_box [get_modules -filter mark_black_box]
add_black_boxes -modules $to_black_box
```

add_cdp_test

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Creates a new test in the CDP.

Usage

```
add_cdp_test test_name [-pattern pattern_file] [-support_pattern_files support_pattern_file ...]
```

Description

Creates a new test in the CDP. The test is based on the specified pattern file.

The newly created test enables you to perform two test operations:

- Run the pattern file to determine the pass/fail status.
- Run the pattern file and collect failing data.

Arguments

- *test_name*
A required string that specifies the name of the test.
- -pattern *pattern_file*
An optional switch and string pair that specifies the directory path for a standalone SVF or STIL test pattern file that is associated with the test.
- -support_pattern_files *support_pattern_file* ...
An optional switch and string pair that specifies one or more pattern files that are associated with the pattern file specified by the -pattern switch.

Examples

The following example adds a test pattern file named *pat.svf* to the CDP and creates a test named *test1* for the *pat.svf* pattern file.

```
add_cdp_test test1 -pattern ./patterns/pat.svf
```

Refer to “[Running Non-Tessent IJTAG Instruments](#)” in *Tessent SiliconInsight User’s Manual for Tessent Shell* for a sample usage scenario.

Related Topics

[delete_cdp_test](#)

[execute_cdp_test](#)

add_cell_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Constrains scan cells (also non-scan cells for CX, TX, DX, and SX constraints) to a constant value.

Usage

```
add_cell_constraints {-Drc C6} | {{{chain_name cell_position} | pin_pathname |
  {-Chain chain_name} | {-Clock clock_name [-Type {Latch | Flop}]}
  -Instances instance_name ...} {C0 | C1 | CX | OX | XX | TX | DX | SX | C0DX | C1DX}
  [-All_patterns | -Scan_patterns]}
```

Description

For all contexts, you can identify a particular scan cell either by specifying a scan chain name along with the cell's position in the scan chain, or by specifying an output pin pathname that connects to a scan memory element. The constraint value that you specify is placed at either the output pin or the scan cell MASTER. The "patterns -scan" context additionally provides the -Chain and -Clock switches for identifying groups of scan cells to receive a particular constraint.

The rules checker audits the correctness of the data that defines the constrained scan cells immediately after scan cell identification. The checker identifies all invalid scan cell constraints and an error condition occurs.

In the case of scan cells with improper controllability or observability, rather than rejecting these circuits, you can constrain (or mask) their controllability or observability.

Note

Adding constraints can lower test coverage.

Arguments

- **-Drc C6** ("patterns -scan" context)

A switch and literal pair that specifies to add a DX cell constraint to each latch and flip-flop that results in a C6 violation during DRC. Because this switch could have a big impact on the test coverage, we strongly recommend that you use the "set_simulation_options -C6_mask_races on" command to resolve C6 violations that occur when either the data port is faster than the clock port, or when both ports have almost the same delay and it is indeterminate as to which port is faster. For more description of these issues, see the -C6_mask_races argument description for the [set_simulation_options](#) command.

- ***pin_pathname***

A string that specifies the name of one of the following types of pins:

- An output pin of the scan cell.
- An output pin directly connected through only buffers and inverters to the output of a scan memory element. The scan memory element is set to the value that you specify such that the pin is at the constrained value.
- An output pin of a non-scan cell if you are applying a CX, TX, DX, or SX constraint.

Except as noted above, the pin pathname must resolve to a scan memory element. Buffers and inverters may reside between the pin and the memory element.

You can also use an introspection command to generate a Tcl collection of pins. For example:

```
add_cell_constraints [get_gate_pins GO_ID_REG_reg_*/q] OX
```

- ***chain_name cell_position***

A string pair that specifies the name of the scan chain and the position of the cell in the scan chain. The scan chain must be a currently-defined scan chain and the position must be an integer where 0 is the scan cell closest to the scan-out pin. You can determine the position of a cell within a scan chain by using the `report_scan_cells` command.

The MASTER memory element of the specified scan cell is set to the value that you specify; there is no inversion. However, the tool may invert the output pin of the scan cell if there is anything between it and the MASTER memory element if inversion exists between the MASTER and the scan output pin of the scan cell only.

- **-CHain *chain_name* (“patterns -scan” context only)**

A switch and string pair that places cell constraints on all cells in the specified scan chain, except any that are already constrained; this switch does not override a pre-existing cell constraint on a cell. This switch is valid in non-Setup system modes only.

- **-Clock *clock_name* (“patterns -scan” context only)**

A switch and string pair that adds cell constraints to all latches and flip-flops controlled by the clock, `clock_name`. If the cell that includes the latch or flip-flop is already constrained, this switch does not override the pre-existing constraint. This switch is valid in non-Setup system modes only.

Note

This switch only supports constraint types OX, DX and SX.

- **-Type Latch | Flop (“patterns -scan” context only)**

An optional switch and literal pair that limits the `-Clock` switch’s action to adding cell constraints on just the latches or just the flip-flops controlled by the clock, `clock_name`. This switch is valid in non-Setup system modes only.

- -Instances *instance_name* ...

An optional switch and string pair that specifies one or more instance names upon which to add cell constraints. This switch supports all types of constraints for scan cells inside the specified instance.

This switch also supports all types of constraints for non-scan cells and transparent latches in the scan path inside the specified instance, except for the following cases:

- If the state element is learned as TIE-0 or TIE-1, you cannot add any cell constraint.
 - If the DRC learns the state element with loading value 0 or 1 when switching to capture, you cannot add cell constraints C1 and C1DX to the state element with loading value 0, or add constraints C0 and C0DX to the state element with loading value 1.
 - If the DRC analysis classifies the state element as TIE-X during capture, you cannot add C0, C1, C0DX, and C1DX cell constraints to this state element.
 - If the DRC analysis classifies the state element as a transparent latch during capture, you cannot add C0, C1, C0DX, or C1DX cell constraints to this state element.
 - You cannot add OX cell constraints to non-scan cells or transparent latches in the scan path.
- -Scan_patterns (“**patterns -scan**” context only)

An optional switch that applies the cell constraint only when creating scan test patterns.

- -All_patterns (“**patterns -scan**” context only)

An optional switch that applies the cell constraint when creating all patterns (scan and chain test patterns). Note that this switch is not valid with the -Drc switch in the same command line. This is the default.

Note

“**dft -edt**” context — if you specify many binary constraints, the tool may not be able to create chain test patterns that satisfy all the constraints.

- Constraint Values

C0

A literal that constrains the scan cell to load value 0 only.

C1

A literal that constrains the scan cell to load value 1 only.

CX

A literal that specifies to simulate the loaded scan cell or non-scan value as unknown (uncontrollable).

OX

A literal that specifies to simulate the unloaded scan cell value as unknown (unobservable).

XX

A literal that constrains the scan cell to be both uncontrollable and unobservable.

TX

(“patterns -scan” context only) A literal that constrains the scan cell or non-scan cell to TIE-X during test generation and simulation. Additionally, the logic value X is loaded into and unloaded from the scan cell.

DX

(“patterns -scan” context only) A literal that specifies for the loaded value to remain until the cell (scan or non-scan) is disturbed by any on clock. When the cell is disturbed, the output value of the cell becomes X for subsequent cycles until the next scan load initializes it to a new value. The cell unloads an X if disturbed, but if not disturbed unloads the loaded value. The tool does not use a scan cell constrained to DX as an observation point.

If you use “add_cell_constraints -drc c6”, the tool applies a DX constraint automatically to each latch and flip-flop that results in a C6 violation during DRC. See the description of the “-Drc C6” argument for more information.

SX

(“patterns -scan” context only) Similar to DX except that when the cell is disturbed by any on clock, the output value of the cell becomes X only if the captured value is different from the loaded (or initialization) value. The tool does not use a scan cell constrained to SX as an observation point.

Note

 If “set_drc_handling d8 warning” is in effect for DRC, the tool automatically applies an SX cell constraint to each D8 failing master cell. This prevents D8-related simulation mismatches when you verify the patterns in a timing based simulator, but may reduce coverage. If you use “set_drc_handling d8 note” for DRC, the tool does not apply SX cell constraints for D8 violations, which ensures test coverage is not affected. But, you should use note handling only for cell architectures you know do not produce mismatches.

C0DX

(“patterns -scan” context only) A literal that constrains the scan cell to both load value 0 only and to keep the loaded value until the cell is disturbed by any on clock (C0 and DX). After the clock disturbance, the unload data is X (masked).

C1DX

(“patterns -scan” context only) A literal that constrains the scan cell to both load value 1 only and to keep the loaded value until the cell is disturbed by any on clock (C1 and DX). After the clock disturbance, the unload data is X (masked).

[Table 3-3](#) shows how cell constraints affect the cell during load-capture-unload. The table shows the unloaded (expected) value of the cell given three possible scenarios during capture:

- **Cell Not Disturbed** — All of the cell's clock/set/reset ports are off.
- **Cell Disturbed (same value captured)** — At least one of the cell's clock/set/reset ports are not off (either on or X), and the new stable capture value is the same as the old value in the cell. Because the tools perform a timeless simulation, the cell's new capture value may not be predictable for this scenario (for example, if a timing exception path drives this cell).
- **Cell Disturbed (different value captured)** — At least one of the cell's clock/set/reset ports is not off (either on or X), and the new stable capture value is different from the old value in the cell.

Note that the table uses 'a' and 'b' to represent different Boolean values (for example, if a=1, then b=0 or X).

Table 3-3. Example Cell Value Changes With Different Constraints for Scan Patterns

Cycle: Constraint	Load Loaded Value (initialized value)	Capture			Unload Unloaded Value
		Cell Not Disturbed	Cell Disturbed (same value captured)	Cell Disturbed (diff. value captured)	
No constraint	a	a	a	b	same as capture value
C0	0	0	0	b	same as capture value
C1	1	1	1	b	same as capture value
CX	X	X	X	b	same as capture value
OX	a	a	a	b	X
XX	X	X	a	b	X
TX	X	X	X	X	X
DX	a	a	X	X	same as capture value
SX	a	a	a	X	same as capture value
C0DX	0	0	X	X	same as capture value
C1DX	1	1	X	X	same as capture value

To help determine the appropriate constraint type for your situation, refer to [Table 3-4](#).

Table 3-4. Constraint Type Recommendations

Loading value reliable?	Unloading value reliable?	Capture value reliable?	Constraint
No	No	No	TX
No	No	Yes	XX
No	Yes	Yes	CX
Yes	No	Yes	OX
Yes	N/A	Yes if no clock is pulsed	DX
Yes	N/A	Yes if same value is captured	SX

Table 3-5 shows, for chain patterns, the different load and unload values of a scan cell with different constraints applied. Notice for chain patterns that CX, XX and TX are equivalent, and DX and SX are the same as no constraint.

Table 3-5. Example Scan Cell Value Changes With Different Constraints for Chain Patterns

Constraint	Loaded Value	Unloaded Value
No constraint	a	a
C0	0	0
C1	1	1
CX	X	X
OX	a	X
XX	X	X
TX	X	X
DX	a	a
SX	a	a
C0DX	0	0
C1DX	1	1

Examples

Example 1

The following example applies one constraint for use during the generation of scan patterns and one constraint for use during the generation of all patterns. Then it displays a list of all the constrained scan cells:

```
add_cell_constraints chain1 5 c0
add_cell_constraints /reg_d2_/Q OX -all_patterns
report_cell_constraints

// constraint chain   cell   cell_instance constraint   pattern scope
//   value   name   position   name   properties
// -----
//   CO     chain1   5           (Dynamic) Scan Patterns only
//   OX     chain4   7   /reg_d2_/Q   (Dynamic) Chain + Scan Patt's
```

Example 2

The following example constrains all the remaining scan cells in the chain1 scan chain to a constant one:

```
add_cell_constraints -chain chain1 c1
```

Example 3

The following example solves C6 rule violations resulting from DRC:

```
add_cell_constraints -drc c6
```

Example 4

The following example adds an OX constraint to all flip-flops controlled by clock /clk1:

```
add_cell_constraints -clock /clk1 -type flop OX
```

add_cell_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Specifies DFT library models for user-defined test points, system-generated test points, and system-generated test logic.

Usage

```
add_cell_models dftlib_model -Type  
  {BUffer | INVerter | AND | OR | NAND | NOR | XOR | CLOCK_BUffer  
  | {MUX mux_select mux_in0 mux_in1}  
  | {DFF clock data_in [-POSEDGE_clock | -NEGEDGE_clock]}  
  | {LATCH enable data_in [-ACTIVE_HIGH_clock | -ACTIVE_LOW_clock]}  
  | {SCAN_CELL clock data_in [-POSEDGE_clock | -NEGEDGE_clock]} }
```

Description

When adding test logic circuitry, multiple models from the DFT library are used. The `cell_type` attribute in the library model description specifies the components available for use as test logic. You can use the `add_cell_models` command instead of defining the `cell_type` attribute in the library model description.

For more information on the design library attribute, see [cell_type](#) in the *Tessent Cell Library Manual*.

Note

 The `add_cell_models` command does not recognize `celldefine` cells as library cells and issues an error stating that these cells are not found in the library.

Arguments

- *dftlib_model*
A required string that specifies the name of a cell model in the DFT library used for test logic, buffer tree, lockup cell, or test point insertion.
- **-TYPE**
A required switch and argument pair that specifies a model type. Options include the following:
 - INVerter** — A literal specifying an inverter cell.
 - AND** — A literal specifying an AND cell.
 - BU**ffer — A literal specifying a buffer cell.
 - OR** — A literal specifying an OR cell.
 - NAND** — A literal specifying a NAND cell.

NOR — A literal specifying a NOR cell.

XOR — A literal specifying an exclusive OR cell.

CLOCK_BUFFER — A literal specifying a clock buffer cell.

MUX *mux_select mux_in0 mux_in1* — A literal and three strings specifying a 2-1 multiplexer and the names of the selector pin and both data pins.

SCAN_CELL *clock data_in* [-POSEDGE_clock | -NEGEDGE_clock] — A literal and two strings specifying a mux-DFF scan cell with the following input pins: clock, data, scan in, and scan enable

You must specify the names of the clock and data pins only of the DFT library cell model. You may also include an optional switch to specify the inversion on the clock pin. This option works in conjunction with the [add_tied_signals](#) command.

DFF *clock data_in* [-POSEDGE_clock | -NEGEDGE_clock] — A literal and two strings specifying a D flip-flop with input pins clock and data. You must specify the names of the clock and data pins only of the DFT library cell model. This option works in combination with the [add_tied_signals](#) command. If you are defining this model for use with lockup cells, you may also use an optional switch to specify the overall inversion on the clock pin.

LATCH *enable data_in* [-ACTIVE_HIGH_clock | -ACTIVE_LOW_clock] — A literal and two strings specifying a D latch with input pins enable and data. You must specify the names of the enable line and the data pin only of the [DFT library cell model](#). If you are defining this model for use with lockup cells, you may also use an optional switch to specify the overall inversion on the clock pin. If you use this command to add an active_low latch, you must specify “`add_cell_models dftlib_model -type latch enable data -active_low_clock`”. The default is `-active_high_clock`.

Examples

The following example shows a typical use of test logic involving the set, reset, and clock pins on sequential elements (flip-flops). The tool can usually ensure controllability of sequential elements with model types of And, Or, and, Mux.

```
add_clocks 0 clk
set_test_logic -set on -reset on -clock on
set_system_mode analysis
...
add_cell_models and2 -type and
add_cell_models or2 -type or
add_cell_models mux21h -type mux si a b
```

add_chain_masks

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup and analysis, when EDT is off

Mode: setup only, when EDT or LBIST is on

Mode: setup only for -Load_value switch

Mode: setup only for -instance -block_chain_index_list switch pair

Mode: setup only for -cell_constraints switch

Masks the load, capture, and unload values on the specified scan chains during simulation.

Usage

Available when EDT is Off

```
add_chain_masks chain_name... [-Cell_constraints {OX | XX | TX}] [-UNload_value X]
```

Available when EDT is On

```
add_chain_masks {chain_name... | -INStance instance_name -Block_chain_index_list  
block_chain_index_list ...} [-Cell_constraints {OX | XX | TX}]  
[-USed_chains {OFF | ON}] [-Load_value {0 | 1}] [-UNload_value {X | 0 | 1}]
```

LogicBIST Simulation

```
add_chain_masks {chain_name... | -INStance instance_name -Block_chain_index_list  
block_chain_index_list ...} [-Cell_constraints {OX | XX | TX}]  
[-Load_value {0 | 1}] [-UNload_value {0 | 1}]
```

Description

The `add_chain_masks` command enables you to mask specified scan chain values from the test results. This command also enables you to specify a circuit response (0/1) to the compactor.

You can use this command to specify that custom masking logic exists between the scan chain outputs and the compactor (when EDT is ON), between the scan chain outputs and output pins (when EDT is OFF), or on the input of the scan chains. You must create and appropriately control the custom masking logic.

Logic BIST Simulation

For logic BIST simulation, this command enables you to specify the scan chains that are masked during fault simulation and their load and unload values. This is useful to get around design issues or broken scan chains post manufacturing. If you use the hybrid TK/LBIST controller, then this command is used to specify the scan chains that need to be masked and the constrained load values for those chains. The tool automatically creates the data to be loaded into the static masking register to implement the masking. On the other hand, if you use your own LBIST controller, then this command enables you to specify the chain masking values corresponding to the hardware that you have added.

When you use a single scan chain mask register to mask a group of scan chains, the `add_chain_masks` command automatically applies the masking information from the specified masked chain to all other scan chains in the group.

Pattern Generation with EDT On

When using the Hybrid EDT/LBIST controller in EDT mode, and you use a single scan chain mask register to mask a group of scan chains, the `add_chain_masks` command automatically applies the masking information from the specified masked chain to all other scan chains in the group.

Pattern Generation with EDT IP TCD and Unused Chains

The EDT IP TCD flow enables you to specify that a chain is present but inactive and not to be traced. You specify these inactive (*unused*) chains by using a core instance (using `-Instance`) and the list of chain indices on the EDT controller instead of specifying chain names. You identify the inactive chains with the `-used_chains` switch. The `-used_chains` switch refers to the chain(s) references and is used as follows:

- `-used_chains OFF` — Tracing of the scan chain(s) is turned off.
- `-used_chains ON` — Tracing of the scan chain(s) is enabled (default).

If the chain is referenced using a core instance, then specification of `-used_chains off/on` is mandatory.

Arguments

- ***chain_name...***
Required, repeatable string that specifies the name of a scan chain in the current design.
- **`-INStance instance_name`**
Required switch and value that specifies an EDT core instance. Must be specified as a set with `-Block_chain_index_list`. When this set is used, the masking applied to the specified chain is OX.
- **`-Block_chain_index_list block_chain_index_list...`**
Required switch and value that specifies a list of chain indices on the EDT controller. Must be specified as a set with `-INStance`. When determining chain indices for this argument, the first chain on the specified instance is counted as “1”. When this set is used, the masking applied to the specified chain is OX.
- **`-Cell_constraints OX | XX | TX`**
Optional switch and literal pair that specifies the cell constraints and observe values for the masking of the specified scan chain(s).
 - OX — Load and capture values are applied, and the fault observation is not included in the results.

XX — Load and unload values are not applied, and values are captured normally for all scan cells in the scan chain for multiple-cycle tests.

TX — All scan cell values are tied as X.

- **-Load_value 0 | 1**

Optional switch and literal pair that specifies the value that is applied to the (internal) scan chain input. Options are:

0 — Specifies the load value is 0.

1 — Specifies the load value is 1.

For EDT, this command enables you to load a value (0/1) at the input of the specified (internal) scan chains. It is assumed that you insert the hardware that constrains the loading value.

For LBIST, this command is used to specify the value (0/1) to be loaded at the input (internal) of the scan chains. The value loaded should be consistent with the hardware that has been added to constrain the loading value at the scan chain inputs.

If there are cell constraints added on a scan chain and also “`add_chain_masks -load_value`” is applied on the same chain, the tool issues an error. EDT Finder is turned off automatically when using “`-load_value`” for EDT.

- **-UNload_value X | 0 | 1**

Optional switch and literal pair that specifies the unload value used to calculate the circuit response. Options include:

X — Specifies the unload value is X. This value is valid with EDT On or Off. This value is not valid for Logic BIST simulation.

0 — Specifies the unload value is 0. This value is valid only for EDT On, and for Logic BIST simulation.

1 — Specifies the unload value is 1. This value is valid only for EDT On, and for Logic BIST simulation.

- **-USed_chains Off | ON**

Optional switch and literal pair that specifies whether the tool traces chain references. This switch is only supported with EDT core instances. Refer to “[add_core_instances](#)” on page 158. Choose from the following:

Off — Tracing of the scan chain(s) is turned off.

ON — Tracing of the scan chain(s) is enabled (default).

The following usage conditions apply:

- If a bypass chain only includes unused chains, then the tool does not add the chain.
- If a bypass chain includes a mix of used and unused chains, the tool issues a warning.

- If all bypass chains have unused chains such that there are no bypass chains left to add, the tool issues an error message.

If one or more chains are defined as unused, a message indicating the number of unused scan chains and that they are not traced is shown in the summary of the scan tracing when the system transitions to analysis mode (see “[Example 3](#)” on page 135). Any cells belonging to those unused chains (and not part of other traced chains) are treated as non-scan cells because they are not traced.

For further details on using this switch in the TCD flow, refer to the section “[Pattern Generation with EDT IP TCD and Unused Chains](#)” on page 133.

Examples

Example 1

The following example does not apply load values (no controllability) or unload values (no observability) and uses all the cells from *chain1* during a multicyle test. The 0 unload value is used to calculate the circuit response for the external channels.

```
add_chain_masks chain1 -cell_constraints xx -unload_value 0
```

Example 2

The following example shows the `add_chain_masks` in the pattern -scan context. The command masks the scan chain input by loading a 0, and masks the scan chain output by unloading a 0 on chains *chain1* and *chain2*.

```
add_chain_masks chain1 chain2 -load_value 0 -unload_value 0
```

```
report_chain_masks
```

```
// Masked scan chain  Load value  Unload value  Cell constraints
// -----
//      chain1         0             0             OX
//      chain2         0             0             OX
```

Example 3

In the following example, this command masks chain index 2 of the instance `corea_rtl2_tessent_edt_c1_inst`, which originally contains 15 scan chains:

```
add_chain_masks -instance corea_rtl2_tessent_edt_c1_inst -block_chain_index_list 2 \
-used_chains off -unload_value 0
```

The scan chain tracing summary indicates that only 14 chains are traced and 1 chain is not traced:

```
set_system_mode analysis
```

```
...
// -----
// Begin EDT Finder analyses.
// -----
// Finding EDT logic.
// Finding internal scan chains.
// EDT Finder completed, EDT blocks=1, scan chains=14, CPU time=0.01 sec.
// -----
// Chain = corea_rtl2_tessent_edt_c1_inst__chain_1 successfully traced with
// scan_cells = 45.
// Chain = corea_rtl2_tessent_edt_c1_inst__chain_3 successfully traced with
// scan_cells = 45.
...
// Chain = corea_rtl2_tessent_edt_c1_inst__chain_13 successfully traced with
// scan_cells = 45.
// Chain = corea_rtl2_tessent_edt_c1_inst__chain_14 successfully traced with
// scan_cells = 45.
// Chain = corea_rtl2_tessent_edt_c1_inst__chain_15 successfully traced with
// scan_cells = 42.
// 626 scan cells have been identified in 14 scan chains. 1 scan chain is defined
// as unused and thus not traced.
```

add_clocks

Context: all contexts

Mode: setup

Adds scan or non-scan clocks to the clock list for proper scan operation.

Usage

For synchronous source clocks:

```
add_clocks [off_state] port_list [-PULSE_Always | -PULSE_In_capture] [-Label label]  
[-dft_inject_node name] [-no_dft_connections]
```

```
add_clocks [off_state] pin_list [-PULSE_Always | -PULSE_In_capture] [-Label label]  
[-PSEUDO_port_name name] [-CAPture_only] [-silent] [-dft_inject_node name]  
[-no_dft_connections]
```

```
add_clocks [off_state] port_list [-FREQ_Multiplier int -PULSE_Always] [-Label label]  
[-dft_inject_node name] [-no_dft_connections]
```

For asynchronous source clocks:

```
add_clocks port_list {-PERiod time [s | ms | us | ns | ps | fs]} [-FREQ_Multiplier int]  
[-Label label] [-dft_inject_node name] [-no_dft_connections]
```

```
add_clocks pin_list {-PERiod time [s | ms | us | ns | ps | fs]} [-PSEUDO_port_name name]  
[-FREQ_Multiplier int] [-Label label] [-silent] [-dft_inject_node name]  
[-no_dft_connections]
```

For generated clocks (for ICL extraction and memory BIST pre-DFT DRC) patterns -ijtag and dft (with no sub context):

```
add_clocks pin -REFERENCE {pin | port | pseudo_port}  
[-REFERENCE_Inv {pin | port | pseudo_port}] [-FREQ_Multiplier int]  
[-FREQ_Divider int] [-PSEUDO_port_name name] [-Label label] [-dft_inject_node name]  
[-no_dft_connections]
```

For adding a clock branch (for ICL extraction and memory BIST pre-DFT DRC):

```
add_clocks pin [-Branch] [-Label label]
```

Description

Declares a pin or a port as a clock. The defined clock may be of type source or a generated source. It may also be of type branch. The permitted types of clocks you can define depends on the current context you are using.

A clock is defined as being an asynchronous source when it is defined with a -period option. A clock is defined as generated when it has a -reference option. A clock is defined as a branch when it has the -branch option. Otherwise, the clock is considered a synchronous source. The various clock types are illustrated in [Figure 3-1](#). The source clock represented with the black symbols are shown as asynchronous sources but they could also be synchronous sources. An asynchronous clock is free running and pulses with an arbitrary period. A synchronous clock

pulses or is kept idle under the control of the tester or in the ATPG simulator. The idle state is controlled using the `off_state` value.

Figure 3-1. Illustration of Various Clock Types

For ATPG and scan DRC, only synchronous clocks are supported. Branch clocks are ignored and generated clocks are converted into synchronous clocks by ignoring the specified `-reference`, `-freq_divider` and `-freq_multiplier` options. You can constrain a clock port to its off-state in order to suppress its use as a capture clock during the ATPG process.

For ICL extraction and memory BIST pre-DFT DRC, all clock types are supported. This enables you to fully describe the complete functional clock network as it pertains to the different instruments and test circuitry as well as by the various memories.

During ICL extraction, clock sources, generated clocks and branch clocks are represented with ICL constructs. Clock sources defined on ports of the current design are reported as `ClockPorts` with the `tessent_clock_periods` attribute capturing its period. The value of the `tessent_clock_periods` attribute is “all <period>”. This is to be ready for the time when the tool enables a clock to have a different period for different test modes. Today, there is only period described in ICL and it applies to all modes.

```
ClockPort <name> {  
    Attribute tessent_clock_periods = "all <real>ns";  
}
```

The clocks defined on internal pins with the `add_clocks` command are captured in ICL using a module named `<design_name>_add_clock_<int>` as shown here:

```
Module <design_name>_add_clock_<int> {  
    // Created by ICL extraction  
    Attribute tessent_clock_type = "source|generated|branch";  
    ClockPort <input_name>;  
    ToClockPort <output_name> {  
        Source <input_name>;  
        FreqMultiplier <int>;  
        FreqDivider <int>;  
    }  
}
```

Those ICL modules are created only if the internal clock pin is found:

- When ICL Extraction traces from a module that is matched to an ICL module.
- When ICL Extraction traces backwards from a primary output that has been declared as a ToClockPort by means of “`add_icl_ports portname -type to_clock`”.
- When ICL Extraction traces from another internal clock pin that has been found before.

In short, those ICL Modules representing the internal clocks are created only if there is something described in ICL to which the internal clock is connected.

The clock label is stored using the attribute `tessent_clock_domain_labels` when instantiating the ICL module. The `pin_name` value reflects the pin name in the design relative to the current design. This information is useful to generate SDC as the clock pin in the design is identified in the ICL instance.

```
Instance add_clock_inst_<int> Of <design_name>_add_clock_<int> {
    InputPort ClockIn = <source_name>;
    Attribute tessent_clock_domain_labels = "<label_name> {<pin_name>}";
}
```

When issuing the [set_current_design](#) in the `dft` context, source or generated clocks modeled in ICL are automatically inferred as `add_clocks`. This is done so that you do not have to declare them manually in order to perform the memory BIST pre-DFT DRC rules [Scan Cell Data Rules \(D Rules\)](#) to `DFT_C5`. Those clocks are automatically deleted when entering the patterns `-ijtag` context so that ICL extract sees your real ICL modules. To have your clocks automatically extracted during design elaboration, the ICL module matching the design module must have the syntax illustrated below where a ToClockPort exists with a Source pointing to a ClockPort on the same module. You use the Period element to model internal oscillators and the FreqMultiplier and FreqDivider elements to model PLLs and clock dividers. If your PLLs and clock dividers are programmable, you can easily enable their programming using IJTAG if you follow the description found in the [ProcedureStep](#) section.

```
Module <module_name> {
    ClockPort <input_name>;
    ToClockPort <output_name> {
        Source <input_name>;
        FreqMultiplier <int>;
        FreqDivider <int>;
        Period <int><time_units>;
    }
}
```

Use the [report_clocks](#) command after having run the [set_current_design](#) command in the `dft` context to show the inferred clocks, if any were inferred. They have the “`inferred_icl_clock<int>`” naming convention, as shown below. Use the [report_ijtag_instances](#) command to report the design instance for which an ICL module was matched. Use the “`set_design_sources -format`” ICL command to modify the search path for ICL files.

add_clocks

User-defined Clock (1):

=====

Generated Clock

=====

Name	Label	Reference	FreqMult	Pin(s)
inferred_icl_clock0	ck0	clk_div/clk_in	1 / 4	clk_div/clk_out

Arguments

- *off_state*

An optional literal that specifies the off state of the clock. This option is only used for synchronous clock sources as asynchronous and generated clocks cannot be stopped. The off state of a branch clock is inferred from the off state of the clock in its fanin. The choices are:

0 — A literal specifying the off-state value is 0 (default value).

1 — A literal specifying the off-state value is 1.

Note

The tool ignores the *off_state* value when specified for asynchronous and generated clocks.

- *pin_list*

A repeatable string that lists the internal pins to define as clocks. The strings can include any number of asterisk (*) and question mark (?) wildcard characters and they must match pin names in the current design.

- *port_list*

A repeatable string that lists the primary input ports to assign as clocks. This string can include any number of asterisk (*) and question mark (?) wildcard characters and they must match port names on the current design.

- *-PSEudo_port_name name*

An optional switch and string pair that specifies the name for a new primary input clock pin that drives all of the internal pins specified with the *pin_list* argument. The name argument must be a simple name that begins with an alpha character and can contain only alphanumeric characters and underscore characters ('_'). Wildcards are not permitted. In ATPG application, you can use this option to map a list of internal clock pins to a single pseudo port. In all other application, the *pin_list* can only include one pin name when specifying the *-pseudo_port_name* option so that each internal clock is associated with a unique pseudo port name.

- *-CAPture_only*

An optional switch specifying that the corresponding pseudo port is only treated as a source clock during capture. For test procedures other than capture, the tool treats this clock pin as

an internal pin; therefore, its simulation value is decided by its driver in the netlist. An event on a `capture_only` clock in a non-capture procedure results in a [P61](#) warning during DRC. This setting does not extend the `capture_only` behavior to equivalent clocks.

- **-PULSE_Always**

An optional switch that identifies the specified pin as a pulse-always clock. A pulse-always clock is pulsed during every cycle of the pattern set.

During ATPG, the clocks you specify as pulse-always are permitted to also pulse with any other clock, ignoring the specified clock restriction setting defined by the [set_clock_restriction](#) command. Pulse-always clocks are automatically pulsed in the external mode of named capture procedures (if present). For more information on named capture procedures, refer to “[Capture Procedures \(Optional\)](#)” in the *Tessent Shell User’s Manual*. Unless you define an asynchronous free-running clock, you must specify the clock in the internal mode of named capture procedures in order to simulate the effect of the clock pulses.

An [Always Block](#) is automatically created in the procedure file if it does not already exist, and the pulse-always clock is pulsed in this block.

- **-PULSE_In_capture**

An optional switch that identifies the specified pin as a pulse-in-capture clock. This information is only used during ATPG and ignored in all other applications. A pulse-in-capture clock is pulsed in every cycle of the capture window. The clock you specify also pulses with any other clock, ignoring the specified clock restriction setting defined using the [set_clock_restriction](#) command.

- **-PPeriod *time_value* [s | ms | us | ns | ps | fs]**

An optional switch and real number pair that specifies the period of a free-running asynchronous clock. The `time_value` is a real number followed by an optional time unit that defaults to “ns.” Note that ATPG and scan DRC treat asynchronous free-running clocks as X values during the capture cycles.

The period of an asynchronous free-running clock affects the timescale and precision of the Verilog test bench. For more information, refer to the description of the “[set time scale](#)” statement in the *Tessent Shell User’s Manual*.

- **-Label *label***

An optional switch and string pair that specifies an arbitrary label for a specified clock. This switch is not valid if the `pin_list` or `port_list` values have more than one element. The label name must be a single string that begins with a letter and consists only of letters, numbers, and underscores. Wildcards are not permitted.

Note

 The clock label that can optionally be specified with the `add_clocks` command only works with the following commands: `get_clocks`, `get_clock_option`, `set_clock_options`, and `delete_clocks`. For all other commands, you must still use the actual clock pin, port, pseudo-port name, or collection returned by the `get_clocks` command.

If you do not specify a label, the tool automatically assigns a label using the following algorithm:

```
if clock is a port
  if clock name begins with "\" (escaped)
    go to "Choose CK# label step"
  else if port is a bus
    take the scalar name followed with _# corresponding to the bit
    index as the label name
    if the label name does not pass the uniqueness check
      go to "Choose CK# label step"
  else if the port name begins with [a-z][A-Z], and only contains
  letters, numbers and _,
    if it passes the uniqueness check
      use the port name as the clock label name
    else
      go to "Choose CK# label step"
If the clock is on a pseudo port
  if the port name begins with [a-z][A-Z], and only contains
  letters, numbers and _,
    if it passes the uniqueness check
      use the port name as the clock label name
    else
      go to "Choose CK# label step"
```

Choose CK# label step:

Take `ck#`, where `#` is chosen as the next available integer such that `"ck#"` is not an already used clock label and is not an existing top-level port name or an existing pseudo port name. The only time the label `"CK#"` is permitted to be used when a port or a pseudo port by the same name already exists is when the clock is defined on that port or that pseudo port itself.

- `-dft_inject_node` *dft_inject_node*

An optional switch and string pair that specifies where the DFT object affecting the clock (for example, a TCK injection multiplexer) should be inserted along the clock path. You can introspect the status of this switch with the “[get_clock_option -dft_inject_node](#)” command and switch.

- `-no_dft_connections`

A Boolean switch that instructs the tool to not infer DFT connections to this clock. When choosing the clock for a dedicated wrapper cell or a `test_point` in the [insert_test_logic](#) command, the clock used by the majority of the flip-flops in the fanin or fanout of the node is normally used. If that clock was added with the `-no_dft_connections` switch, it is not chosen and instead the next majority clock is used. If all clocks the fanin or fanout were

added with the `-no_dft_connections` switch, the largest clock domains in the design without this switch are selected.

- `-FREQ_Multiplier` *int*

An optional switch and integer pair that specifies an integer to reflect the multiplication factor the clock has with respect to its specified `-reference` value.

- `-FREQ_Divider` *int*

An optional switch and integer pair that specifies an integer to reflect the division ratio the clock has with respect to its specified `-reference` value. The option can also be used with the `-period` option to define how a clock frequency is divided from a base period. The tool adds special logic in the Verilog test bench to generate all clocks that have the same base period and make sure they remain coherent during simulation.

- `-REFERENCE` {*pin* | *port* | *pseudo_port*} (“**dft (no sub-context)**” and “**patterns -ijtag**” only)

A switch and string pair that specifies the clock that is the reference of the clock. The multiplication and division relationship between the clock and its reference is described using the `-freq_multiplier` and `-freq_divider` options.

Cascaded clocks should first declare the source clock, followed by the reference clocks.

- `-REFERENCE_Inv` {*pin* | *port* | *pseudo_port*} (“**dft (no sub-context)**” and “**patterns -ijtag**” only)

An optional switch and string pair that specifies the second primary input port if the reference pin is a differential pin.

- `-Branch`

An optional switch that defines a pin or a port as a clock branch. You can use this switch in conjunction with the `-Label` switch.

A clock branch shares a source with one or more clocks but it is not skew-balanced with the other clocks that share the common source. The `-branch` switch is useful for describing branches in a clock tree that are balanced within themselves but not with the other branches of the tree. Refer to [Figure 3-1](#) for a graphical representation of a clock branch.

- `-silent`

An optional switch that suppresses the transcription of notes the tool issues.

Examples

Example 1

The following example adds two external pulse-always clocks with off states of 1:

```
SETUP> add_clocks 1 I2 I3 -pulse_always
```

```
SETUP> report_clocks
```

```
User-defined Clocks (2):  
Sync and Async Clocks  
=====
```

Name	Off State	Constraints	Internal
'I2'	1	Pulse always	No
'I3'	1	Pulse always	No

Note that the `report_clocks` command does not report a label name because, in the case of ports, the tool generates a label name that is identical to the port name.

Example 2

The following example adds an internal clock with an off state of 0. The `add_clocks` command automatically creates a PI at the new clock pin.

```
SETUP> add_clocks 0 u4/u2/CLK  
  
// Warning: Primary input 'u4/I6' is added at pin '/u4/u2/CLK'  
  
SETUP> report_clocks  
  
User-defined Clock (1):  
=====
```

Name	Label	Off State	Constraints	Internal	Pin(s)
u4/I6	ck0	0		Yes	u4/u2/CLK

```
  
SETUP> report_primary_inputs  
  
USER:    '/u4/I6' (internal pin)  
SYSTEM:  '/I1'  
...
```

Note that the `report_clocks` command reports the label name that the tool automatically generates for internal pins.

Example 3

The following example adds two internal clocks and merges them together under a `pseudo_port` name of `port_1`:

```
SETUP> add_clocks 0 u4/u2/CLK u5/u2/CLK -pseudo_port_name port_1  
  
// Note: Primary input 'port_1' is added, merging 2 pins.  
  
SETUP> report_clocks  
  
User-defined Clock (1):  
=====
```

```

Sync and Async Source Clock
=====
-----
Name      Off State  Constraints  Internal  Other Properties  Pin(s)
-----
'port_1'  0          -----
          Yes      Merged internal pin u4/u2/CLK
                               u5/u2/CLK

```

Example 4

The following example adds an external pulse-in-capture clock with a label name:

```
SETUP> add_clocks 0 I2 -pulse_in_capture -label clock_2
```

```
SETUP> report_clocks
```

```
User-defined Clock (1):
```

```
=====
```

```

Sync and Async Source Clock
=====
-----
Name      Label      Off State  Constraints  Internal
-----
'I2'      clock_2    0          Pulse in capture  No

```

Example 5

The following example specifies two asynchronous free-running clocks that are coherent. The overall period for the coherent group is 1000ns. The clock “aclk” pulses 20 times during that period while “bclk” pulses 30 times during that period, both with a 50 percent duty cycle:

```
SETUP> add_clocks aclk -period 1000 ns -freq_multiplier 20
```

```
SETUP> add_clocks bclk -period 1000 ns -freq_multiplier 30
```

```
SETUP> report_clocks
```

```
User-defined Clocks (2):
```

```
=====
```

```

Sync and Async Source Clocks
=====
-----
Name  Off State  Constraints  Internal  Period  Freq. Multiplication
-----
'aclk'  -          Asynchronous  No      1000.00ns  20
'bclk'  -          Asynchronous  No      1000.00ns  30

```

The annotations and comments to document the asynchronous free-running clocks in the pattern files occur in the header section of the pattern file right after the block of comments/annotations

that are labeled “Begin_Verify_Section.” The annotations are grouped in a block with a begin and end annotation. Here is an example of the WGL block:

```
{ Begin_async_clocks }
{   aclk = period: 1000.00ns, divider: 20 }
{   bclk = period: 1000.00ns, divider: 30 }
{ End_async_clocks }
```

All other pattern formats use the identical block structure and syntax within the annotation or comment. The only differences are using the correct annotation or comment punctuation or statements surrounding this block.

Example 6

The following example works in “patterns -ijtag” only. The following commands produce an internal half-speed clock on the ICL module “chip” during ICL extraction:

```
set_design_sources -format icl -y icl_data
set_current_design chip
add_clocks { pll_block/clock1 } -reference clock1 -freq_divider 2
set_system_mode analysis
```

The resulting ICL created by the ICL extraction looks as follows:

```
Module chip {
  // Created by ICL extraction
  ClockPort clock1;
  ...
  Instance block1_I1 Of block1 {
    InputPort ClkA = add_clock_inst_0.ClockOut;
    ...
  }
  Instance add_clock_inst_0 Of chip_add_clock_0 {
    InputPort ClockIn = clock1;
  }
}

// instanced as chip.add_clock_inst_0
Module chip_add_clock_0 {
  // Created by ICL extraction
  ClockPort ClockIn;
  ToClockPort ClockOut {
    FreqDivider 2;
    Source ClockIn;
  }
}
```

add_config_element

Context: unspecified, all contexts

Mode: all modes

Adds a configuration element in the configuration data.

Usage

```
add_config_element [name] [-in_wrapper wrapper_object] [-copy_from config_object_spec]  
    [-before config_object_spec | -after config_object_spec | -first | -last]  
    [-type wrapper | data_wrapper | csv_wrapper | property] [-value value_list]  
    [-replace]
```

Description

The command returns a single element collection that contains the newly-created element.

The behavior of the command is different when adding an element inside a wrapper that fully defines the permitted child elements versus one that permits arbitrary elements. The permitted content of a wrapper is controlled by its metadata description. Wrappers of type single and simple properties exist automatically as soon as their parent wrapper is added. Therefore, these elements cannot be added using this command as they are automatically added when their parents are added. You use the [set_config_value](#) to specify their value.

You can add elements inside a parent wrapper that does not constrain its content (that is, its metadata has the property AllowUnknown set to on), but you need to add everything inside it and define the type of object using the -type property. Refer to [Example 2](#) for an example that creates a configuration tree with no metadata.

Arguments

- *name*

An optional string that specifies the name of the configuration element being added. When using the -in_wrapper option, the name is the relative pathname with respect to the specified wrapper. When not using the -in_wrapper option, the name is the complete pathname with respect to the root of the partition. The parent wrapper of the element must exist before the element can be added to it. For example DftSpecification(moda,rtl) must exist to add the MemoryBist wrapper into it using the “add_config_element DftSpecification(moda,rtl)/MemoryBist” command. The added element must not already exist unless the -replace option is used, in which case the existing element is deleted before being added.

- -in_wrapper *wrapper_object_spec*

An option value pair that specifies that the configuration element is to be added inside a specific wrapper. When the -in_wrapper option is specified, the name option defines a name relative to the specified destination wrapper. The *wrapper_object_spec* can be the complete name of a wrapper relative to the root of the partition or a collection containing a single wrapper element as returned by [get_config_elements](#) or “[get_config_value](#) -object”.

The default partition defines wrappers by the name of tmp(id) that permit unknown elements to be added inside them. If you want to read an arbitrary configuration wrapper into the tool that does not match any defined syntax, you can use the “add_config_element tmp(id)” command to create an empty tmp wrapper. The id can be any arbitrary label and you can create as many tmp wrappers as you need. Once created, you can then use the “read_config_data file -in_wrapper tmp(id)” command to load arbitrary configuration data inside the tmp(id) wrapper. Refer to [Example 2](#) for an example of this usage.

- -copy_from *config_object_spec*

An optional value pair that specifies that the added element is a copy of another element. When the permitted content of the destination parent wrapper is defined with [Wrapper](#), the metadata definition of the source and destination element must be identical (that is, both definitions must reference the same metadata definition). If this is not the case, the tool issues an error message. You can omit the name of the added element when using both the -copy_from and the -in_wrapper options. In this case, the parent wrapper of the copied element and the destination wrapper must be different. If you do not specify the name option, the element is added into the destination wrapper using the leaf_name of the copied object.

- -before *config_object_spec*

An optional value pair that specifies a configuration element that the new configuration element precedes. When you use the -before option with a collection containing a configuration element object, you cannot use the -in_wrapper option because the parent wrapper is extracted from the object. Also, the name option must be a leaf_name with no hierarchical component.

When the *config_object_spec* value is a name, it must be a name relative to the object specified with the -in_wrapper or -copy_from options. If you do not specify either option, it is a name relative to the root of the partition.

The -before option is mutually exclusive to the -after, -first, and -last options. When you specify none of these four options, the tool uses the -last option.

- -after *config_object_spec*

An optional value pair that specifies a configuration element after which to add the new configuration element. When you use the -after option with a collection containing a configuration element object, you cannot use the -in_wrapper option because the parent wrapper is extracted from the object. Also, the name option must be a leaf_name with no hierarchical component.

When the *config_object_spec* value is a name, it must be a name relative to the object specified with the -in_wrapper or -copy_from options. If you do not specify either option, it is a name relative to the root of the partition.

The -after option is mutually exclusive to the -before, -first, and -last options. When you specify none of these four options, the tool uses the -last option.

- **-first**

An optional switch that specifies to add the new configuration element before any other element in the parent wrapper.

The **-first** option is mutually exclusive to the **-before**, **-after**, and **-last** options. When none of these four options is specified, **-last** is assumed.

- **-last**

An optional switch that specifies to add the new configuration element after all other elements in the parent wrapper.

The **-first** option is mutually exclusive to the **-before**, **-after**, and **-first** options. When none of these four options is specified, **-last** is assumed.

- **-type wrapper | data_wrapper | csv_wrapper | property**

An optional value pair that is only needed and permitted when adding a configuration element for which no **Wrapper** exists. When adding an element for which metadata exists, the **-type** option is not permitted because the type of the object is specified in the metadata. When adding an element for which no metadata exists, the **-type** value defaults to “wrapper” when the **-value** option is not specified and to “property” when the **-value** option is specified.

Refer to [Example 2](#) for an example of its usage when adding an element without metadata.

- **-value *value_list***

An optional switch and value pair that is used when adding a configuration element that needs a value. The **-value** option is only used when adding a repeatable property such as the connection property in the [Tdr/DataOutPorts](#) wrapper. The supplied value needs to be a well-formatted Tcl list so as to set a value that contains white spaces and is similar to the following:

```
-value [list "a b c"]
```

- **-replace**

An optional switch that suppresses the error that is normally generated when adding a configuration element with a name that conflicts with an existing element. The error only occurs if the element is defined as not repeatable in the metadata. Instead of an error, the existing element is first deleted.

Examples

Example 1

The following example creates a `DftSpecification` using the `add_config_element` command. The generated configuration data is then reported.

```
set_transcript_style input_only
set spec [add_config_element DftSpecification(moda,ex1)]
set ijtag [get_config_elements IjtagNetwork -in_wrappers $spec]
set host [add_config_element HostScanInterface(ijtag) -in $ijtag]
set mbist [add_config_element MemoryBist -in $spec]
set_config_value ijtag_host_interface -in $mbist HostScanInterface(ijtag)
set ctl [add_config_element Controller(c1) -in $mbist]
set step [add_config_element Step -in $ctl]
set mem_int [add_config_element MemoryInterface(m1) -in $step]
set_config_value memory_library_name -in $mem_int ram12x4
set mem_int [add_config_element ReusedMemoryInterface(m2) -in $step]
set_config_value reused_interface_id -in $mem_int m1
set step [add_config_element Step -in $ctl]
set mem_int [add_config_element MemoryInterface(m3) -in $step]
set_config_value memory_library_name -in $mem_int ram12x8
set mem_int [add_config_element ReusedMemoryInterface(m4) -in $step]
set_config_value reused_interface_id -in $mem_int m3
report_config_data DftSpecification(moda,ex1)
```

```
DftSpecification(moda,ex1) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
    }
  }
  MemoryBist {
    ijtag_host_interface : HostScanInterface(ijtag);
    Controller(c1) {
      Step {
        MemoryInterface(m1) {
          memory_library_name : ram12x4;
        }
        ReusedMemoryInterface(m2) {
          reused_interface_id : m1;
        }
      }
      Step {
        MemoryInterface(m3) {
          memory_library_name : ram12x8;
        }
        ReusedMemoryInterface(m4) {
          reused_interface_id : m3;
        }
      }
    }
  }
}
```

Example 2

The following examples adds a tmp wrapper that enables anything inside it to show how arbitrary configuration data can be created. Notice the use of the -type options when adding a data row and a csv row. The -type option is not needed when adding a wrapper or a property because it automatically defaults to wrapper or property based on the presence of the -value option.

add_config_element

```

set tmp1 [add_config_element tmp(1)]
set n_wpr [add_config_element NormalWrapperExmable(abc) -in $tmp1]
add_config_element -in $n_wpr prop_example -value [list a b c]
set d_wpr [add_config_element DataWrapperExample -in $n_wpr]
# -type is needed otherwise it would default to property as
# -value is not specified
add_config_element -in $d_wpr element1 -type property
add_config_element -in $d_wpr element2 -value 32ns
set c_wpr [add_config_element CsvWrapperExample -in $n_wpr]
add_config_element -in $c_wpr -value [list a b c]
add_config_element -in $c_wpr -value [list d e]
add_config_element -in $c_wpr -value [list f g h] -after <0>
report_config_data $tmp1

```

```

tmp(1) {
  NormalWrapperExmable(abc) {
    prop_example : a, b, c;
    DataWrapperExample {
      element1;
      element2 : 32ns;
    }
    CsvWrapperExample {
      a, b, c;
      f, g, h;
      d, e;
    }
  }
}

```

Related Topics[delete_config_element](#)[get_config_elements](#)[move_config_element](#)

add_config_message

Context: all contexts

Mode: all modes

Adds error, warning, or information messages to configuration elements.

Usage

```
add_config_message -config_object config_object message  
[-error | -warning | -info | -note] [-display]
```

Description

Adds error, warning, or information messages to configuration elements.

Arguments

- **-config_object** *config_object*
A required value that specifies the configuration object to which to add the message specified by the message string. The *config_object* value is the name of a configuration element or a collection containing a single configuration element object.
- *message*
A required string value that specifies the text being added.
- -error
An optional Boolean option that specifies that the messages to be added are of type error.
- -warning
An optional Boolean option that specifies that the messages to be added are of type warning.
- -info
An optional Boolean option that specifies that the messages to be added are of type info.
- -note
An optional Boolean option that specifies that the messages to be added are of type note.
- -display
An optional switch that specifies to also display the error, warning, or information messages in the transcript. Without this option, the message is silently added to the configuration object.
If the [file_path_name](#) and [line_number](#) attributes are set on the configuration object, then the message displays the pathname to the file and the line number in the file where the configuration element is defined. For example:

```
// Warning: /Core(SYNC_1RW_512x64x2)/Memory/OperationSet  
//           Read from file: ./SYNC_1RW_512x64x2.lib, line number: 8
```

Examples

Example 1

The following example adds an error message to a property element. The `-display` option specifies to also report the error message in the transcript window.

```
add_config_message -config_object /tmp(1)/propertyA -error -display \  
"The value A is inconsistent with the design level '[get_design_level]'."
```

Example 2

The following example illustrates the differences between `-error`, `-warning`, `-info` and `-note` as to how the messages are displayed in the transcript window:

```
// Error: /Core(SYNC_1R1W_16x8)/Memory  
//      The memory uses a checkerboard test algorithm SMarchCHKBvcd and has no  
//      column address bits. Memories with checkerboard algorithm and no column  
//      address bits must have BitGrouping property set to the data word size.  
//      The BitGrouping value of this memory is changed to 8.  
  
// Warning: /Core(SYNC_1R1W_16x8)/Memory  
//      The memory uses a checkerboard test algorithm SMarchCHKBvcd and has no  
//      column address bits. Memories with checkerboard algorithm and no  
//      column address bits must have BitGrouping property set to the data  
//      word size. The BitGrouping value of this memory is changed to 8.  
  
//Core(SYNC_1R1W_16x8)/Memory  
//      The memory uses a checkerboard test algorithm SMarchCHKBvcd and has no  
//      column address bits. Memories with checkerboard algorithm and no  
//      column address bits must have BitGrouping property set to the data  
//      word size. The BitGrouping value of this memory is changed to 8.  
  
// Note: /Core(SYNC_1R1W_16x8)/Memory  
//      The memory uses a checkerboard test algorithm SMarchCHKBvcd and has no  
//      column address bits. Memories with checkerboard algorithm and no column  
//      address bits must have BitGrouping property set to the data word size.  
//      The BitGrouping value of this memory is changed to 8.
```

add_config_tab

Context: all contexts

Mode: all modes

Adds one configuration tree tab to the Configuration Data Visualizer window.

Usage

add_config_tab *wrapper*

Description

Adds one configuration tree tab to the Configuration Data Visualizer window.

Arguments

- *wrapper*

An value that specifies the name of the configuration wrapper. The value is either the name of a wrapper or a collection that contains exactly one configuration wrapper. The wrapper is the root wrapper displayed in the tab.

Examples

This example displays a tcd_memory wrapper in the Configuration Data Visualizer window. Notice the use of the get_config_element command to obtain the configuration object. The name could not be used directly in the add_config_tab because the tool only looks in the default partition. The display_specification command displays a DftSpecification in a tab of the Configuration Data window.

```
add_config_tab [get_config_element Core(RAM12x8) -partition tcd]
```

Related Topics

[delete_config_tabs](#)

[display_specification](#)

add_control_points

Context: dft -test_points

Mode: setup, analysis

Specifies user-defined control points during test point insertion.

Usage

```
add_control_points -location pin/port_spec -type {AND | OR} [-clock clock_pin/port]  
[-enable enable_pin/port]
```

Description

Specifies user-defined control points during test point insertion.

Arguments

- **-location *pin/port_spec***
A required switch and string that specifies the pathname to the control point location.
The *pin/port_spec* can be a Tcl list of one or more pins/ports or a collection of one or more pin/port objects.
- **-type {AND | OR}**
A required switch and literal pair that specifies the gate type to be inserted at the control point location.
- **-clock *pin/port_spec***
An optional switch and string pair that specifies the path name of the clock signal used to clock the control point. This can be a collection or list, but should have only one element.
- **-enable *pin/port_spec***
An optional switch and string pair that specifies the path name of an existing net used to enable the control point. This can be a collection or list, but should have only one element.

Examples

Example 1

The following example adds a type OR control point and a type AND control point. For the AND control point it also specifies the path name of the clock signal used to clock the control point:

```
add_control_point -location gc[1] -type OR  
add_control_point -location gd[1] -type AND -clock gclk4  
report_test_points
```

Example 2

The following example specifies the path name of an existing net that is to be used to enable the control points. For the AND control point it also specifies the path name of the clock signal used to clock the control point. Then it proceeds to insert the control points into the netlist:

```
set_test_point_insertion_options -control_point_enable cp_enable  
add_control_point -location ga[1] -type OR -clock buf1/Z  
report_test_points  
...  
set_system_mode analysis  
...  
insert_test_logic
```

Related Topics[add_observe_points](#)[delete_test_points](#)[report_test_points](#)

add_core_instances

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: setup

Adds a core instance to the design by associating the core description currently in memory with the specified core instance(s) in the design.

Usage

```
add_core_instances [-core core_name] [-mode mode_name]  
    {-modules module_objects | -instances instance_objects | -current_design}  
    [-design_id design_id] [-parameter_values {parameter_list}] [-silent]
```

Description

Adds a core instance to the design by associating the core description currently in memory with the specified core instance(s) in the design. If the core description is not currently in memory, you can read it in using the [read_core_descriptions](#) command. You can report the available core descriptions by using the [report_core_descriptions](#) command.

The [read_core_descriptions](#) command must have already been run before using this command.

You can specify the core(s) with which to associate the core description by providing either absolute instance pathnames to the cores or uniquified module names, or by using the `-current_design` switch.

Restriction

 Do not use the `add_core_instances` command to add SSN ScanHost instruments. The ScanHost instances are already inferred from ICL, and the active ScanHost instances are automatically identified.

Arguments

- `-core core_name`

An optional switch and Tcl list that specifies the core name of the core description from which the instantiation should take place. If the `-core` switch is not specified, the tool attempts to match a core description against the module name of the specified module(s) or instance(s). If the tool does not find a direct match for a core description and a module or instance, the tool attempts to identify a match using the tool's default module matching options that are consistent with what synthesis tools typically use. For information on the default module matching options and how they can be changed, see the description for the [set_module_matching_options -suffix_pattern_list](#) option.

If the tool is unable to match a specified module or instance, it issues an error with a reminder that the user can explicitly specify which core description to use with the `-core` switch.

- **-mode** *mode_name*
An optional switch that specifies the mode of the core. This switch is required if the core has multiple modes.
- **-modules** *module_objects*
A required switch and string pair that specifies a Tcl list of one or more object names (hierarchical names) or a collection of one or more objects. The core instances are created for each instantiation of those objects in the design.
- **-instances** *instance_objects*
A required switch and string pair that specifies a Tcl list of one or more object names (hierarchical names) or a collection of one or more objects. The core instances are created for each instance in the list.
- **-current_design**
A required switch that specifies to add the core instance with respect to the current design. This switch is mutually exclusive with the `-modules` and `-instances` switches. The mode of the core instance being added by the `-mode` switch must be different than the mode of the current design specified using the `set_current_mode` command.
- **-design_id** *design_id*
An optional switch and string pair that specifies searching any opened [Tessent Shell Data Base \(TSDB\)](#) for Tessent Core Descriptions that match the *design_id* value.

If you omit the `-design_id` switch and string pair and the added instance has the [design_id attribute](#) set, then the tool performs the matching based on the *design_id* attribute value. The *design_id* attribute is inherited by instance objects from their modules. Additionally, when you use `read_design -design_id design_id`, the *design_id* attribute is set automatically for these modules and instances.

If you do not set the *design_id* and there is only one TCD in the opened TSDBs that matches the core name, the tool loads the *design_id* in memory and adds the core instance. If the TCD is already loaded into memory the `-design_id` switch has no effect and the matching is preformed based on the core and module name.
- **-parameter_values** {*parameter_list*}
An optional switch and parameter list that specifies instrument configuration parameters and their values. The parameter list is one or more parameter value pairs. For example:

```
SETUP> add_core_instances -core cpu_edt -modules cpu_edt \  
-parameter_values {edt_bypass off}
```

The list includes the subset of those parameters that are configurable in the specified instrument. [Table 6-7](#) in the documentation for [set_core_instance_parameters](#) shows the core parameters and their instruments.

The parameters for core instances created with this command can be reported with the [report_core_instance_parameters](#) command. Their parameters may be modified with the [set_core_instance_parameters](#) command.

- -silent
An optional switch that specifies to suppress warning messages.

Examples

Example 1

The “[Retargeting Example](#)” in the *Tessent Scan and ATPG User’s Manual* demonstrates the use of this command in a design context.

Example 2

The following example demonstrates the use of the `-current_design` switch to merge two modes of a core; in this case, the “core” is the top level. In the example, patterns are generated separately for two sub-blocks of a design from the top-level pins. Sub-Block1 is tested as mode M1 of the top level, and Sub-Block2 is tested as mode M2 of the top level. The result, shown in [Figure 3-3](#) on page 163, is the merging of the two pattern sets originally generated for each individual mode into a single pattern set applied at the top level.

The first dofile reads in the top level design and writes out the patterns and core description files for mode M1 targeting Sub-Block1:

```
// Invoke tool to generate patterns for each mode of top_level  
set_context pattern -scan  
read_verilog top_level.v // Read netlist of top_level  
  
// Mode M1 consists of the Sub-Block1 design; the user must blackbox Sub-Block2 and apply  
// constraints to access Sub-Block1  
set_current_mode M1 -type internal  
...  
set_system_mode analysis  
...  
create_patterns  
write_patterns top_levelM1.ascii  
write_core_description top_levelM1.tcd
```

The second dofile reads in the design and writes out the patterns and core description files for mode M2 targeting Sub-Block2:

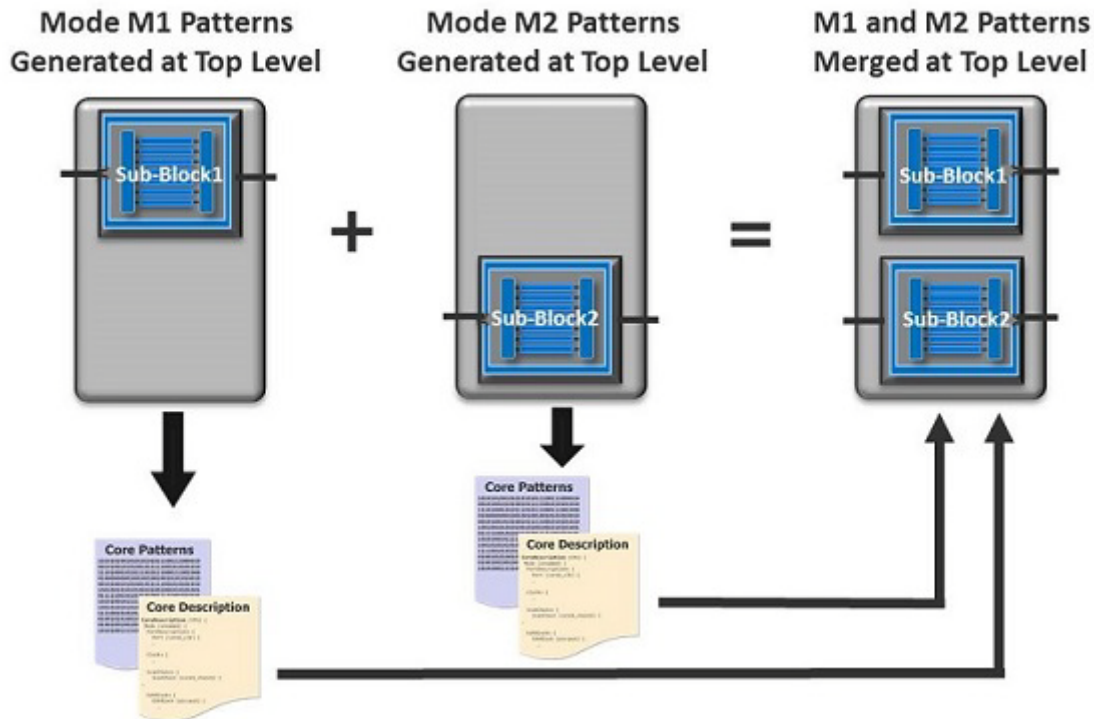

```
// Mode M2 consists of the Sub-Block2 design; the user must blackbox Sub-Block1 and apply  
// constraints to access Sub-Block2  
set_current_mode M2 -type internal  
...  
set_system_mode analysis  
...  
create_patterns  
write_patterns top_levelM2.ascii  
write_core_description top_levelM2.tcd
```

The third dofile merges the two separately generated top-level pattern sets (modes M1 and M2) into a single pattern set:

```
// Invoke the tool again to retarget patterns to top level
set_context patterns --scan_retargeting
...
read_core_description top_levelM1.tcd
read_core_description top_levelM2.tcd
add_core_instance --core top_level --mode M1 --current_design
add_core_instance --core top_level --mode M2 --current_design
set_system_mode analysis

// Mode extracted from ASCII file
read_patterns top_levelM1.ascii
read_patterns top_levelM2.ascii
write_patterns ...
```

Figure 3-2. Merge Patterns Sets Into One Patterns Set

Example 3

The following example demonstrates the use of the `add_core_instances -current_design` switch to merge mode M1 of the current design and mode internal of CoreB. In the example, one pattern set is generated at the top level (mode M1 of the top level) to test Sub-Block1, and a second pattern set is generated at the core level of CoreB. The result, as shown in [Figure 3-3](#), is the integration of the two pattern sets, originally generated for mode M1 of the top level and mode internal of CoreB, into the top level.

The first dofile reads in the top level design and writes out the patterns and core description files for mode M1 targeting Sub-Block1.

```
// Invoke tool to generate patterns for mode M1 of the top level  
set_context pattern -scan  
read_verilog top_level.v // Read netlist of top_level  
  
// Mode 1 consists of the Sub-Block1 design; the user must blackbox any other blocks not  
// targeted, and apply constraints to access Sub-Block1  
set_current_mode M1 -type internal  
...  
set_system_mode analysis  
...  
create_patterns  
write_patterns top_levelM1.ascii  
write_core_description top_levelM1.tcd
```

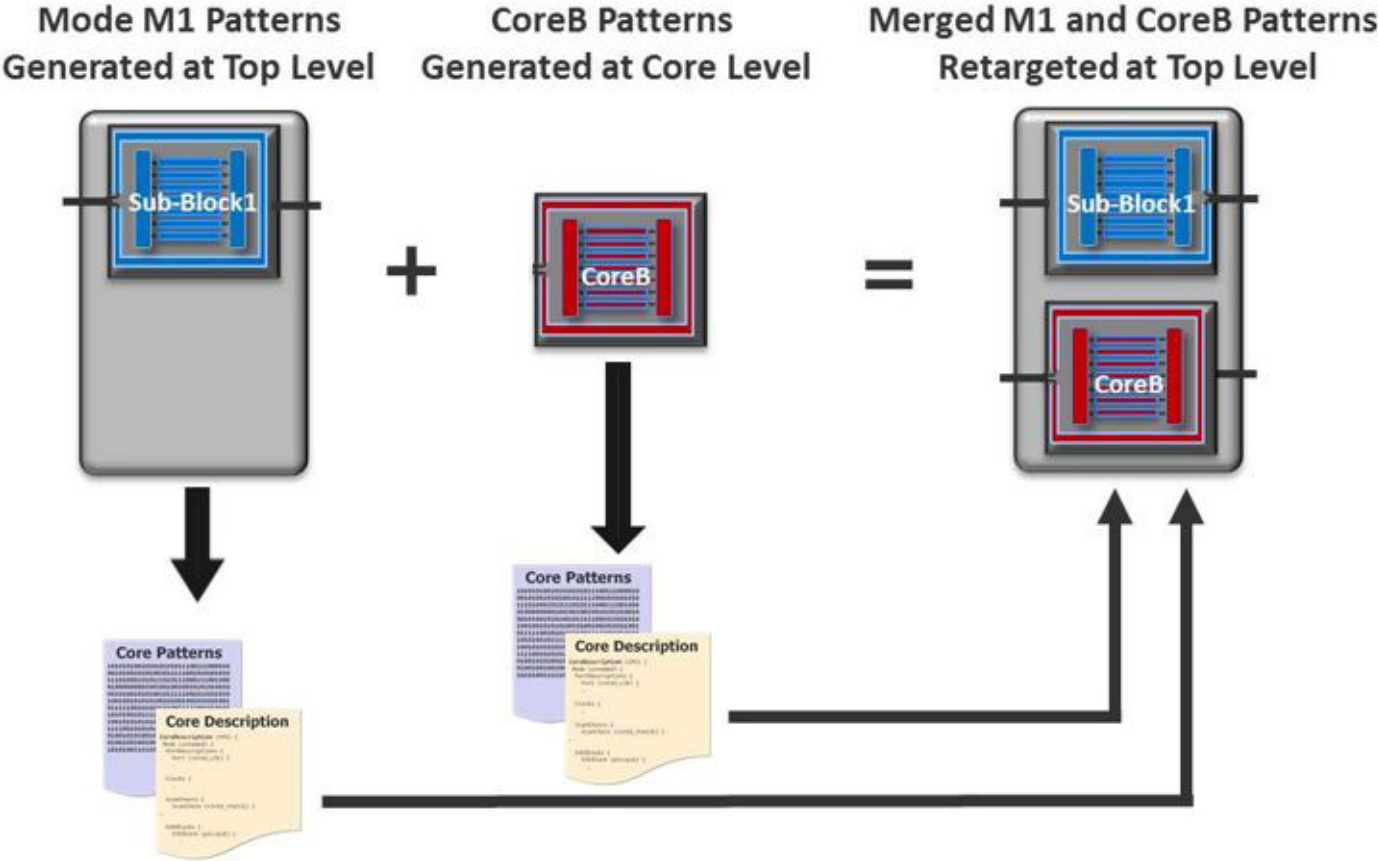

The second dofile reads in the CoreB design and writes out the patterns and core description files.

```
set_system_mode setup  
delete_design  
read_verilog CoreB.v  
set_current_mode internal -type internal  
...  
set_system_mode analysis  
create_patterns  
write_patterns CoreB.ascii  
write_core_description CoreB.tcd
```

The third dofile merges the top level pattern set (mode M1) with the retargeted CoreB patterns.

```
// Invoke tool to retarget patterns to top level  
set_context patterns -scan_retargeting  
...  
read_core_description top_levelM1.tcd  
read_core_description CoreB.tcd  
add_core_instance -core top_level -mode M1 -current_design  
add_core_instance -core CoreB -mode internal -instances /CoreB_i  
...  
set_system_mode analysis  
read_patterns top_levelM1.ascii  
read_patterns CoreB.ascii  
write_patterns ....
```

Figure 3-3. Merging Patterns for Top Level and Core at the Top Level

Example 4

The following example shows the four core descriptions in memory that are matched and then used to add core instances:

```

SETUP> report_core_descriptions

Name                          Mode Name                      Type
-----
* my_design                    retargeting                    retargeting
  m1231                        internal                      internal
  my_module_name_1            internal                      internal
  my_module_name_2            internal                      internal
  my_module_name_3            internal                      internal
    
```

Note: * denotes current design

The corresponding design modules have the same name as the core descriptions. [Table 3-6](#) shows the mapping between the core descriptions and the design instances:

Table 3-6. Mapping of Core Descriptions and Instances

Core	Instance
m1231	inst_4

Table 3-6. Mapping of Core Descriptions and Instances (cont.)

Core	Instance
my_module_name_1	inst_1
my_module_name_2	inst_2
my_module_name_3	inst_3

The following command adds the core instances:

```

SETUP> add_core_instances -instance inst_*

// Added core instance `inst_4`.
// Added core instance `inst_1`.
// Added core instance `inst_2`.
// Added core instance `inst_3`.

```

Example 5

The following example shows the four core descriptions in memory that the tool attempts to match and use to add core instances. The matching options, which can be specified and changed with the `set_module_matching_options` command, default to an empty prefix and a “([0-9]+)?” suffix, which means that the tool tries to match the core name against the module name by adding an underscore followed by a digit to it. The name matching mechanism fails to match all of the modules and an error is issued.

```

SETUP> report_core_descriptions

Name                Mode Name          Type
-----
* my_design         retargeting       retargeting
  m123              internal          internal
  my_module_name    internal          internal
  my_module_name_  internal          internal
  my_module_name_2 internal          internal

```

Note: * denotes current design

The corresponding design modules are:

```

SETUP> get_modules {m123? my_module_name??}

{m1231 my_module_name_1 my_module_name_2 my_module_name_3}

```

Table 3-7 shows the mapping between the core descriptions, modules, and instances:

Table 3-7. Mapping of Core Descriptions With Modules and Instances

Core	Module	Instance
m123	m1231	inst_4
my_module_name	my_module_name_1	inst_1
my_module_name_	my_module_name_3	inst_3

Table 3-7. Mapping of Core Descriptions With Modules and Instances (cont.)

Core	Module	Instance
my_module_name_2	my_module_name_2	inst_2

Attempting to add all core instances in one step produces an error as shown below:

```

SETUP> add_core_instances -instance inst_*

// Error: No core description found to match module 'm1231' of instance
// 'inst_4'. Please use -core to specify the core description to use.

```

Example 6

In this example, there are four core descriptions in memory that can be used to add core instances:

```

SETUP> report_core_descriptions

Name                Mode Name          Type
-----
* my_design          retargeting        retargeting
  m1231              internal           internal
  my_module_name_1   internal           internal
  my_module_name_2   internal           internal
  my_module_name_3   internal           internal

```

Note that * denotes current design

The corresponding design modules have the same name as the core descriptions such that the mapping between the core descriptions and the design instances is as follows:

```

Core                Instance
-----
m1231               inst_4
my_module_name_1    inst_1
my_module_name_3    inst_3
my_module_name_2    inst_2

```

The design instance cores are added:

```

SETUP> add_core_instances -instance inst_*

// Added core instance 'inst_4'.
// Added core instance 'inst_1'.
// Added core instance 'inst_2'.
// Added core instance 'inst_3'.

```

add_dft_clock_enables

Context: dft (with no sub context)

Mode: setup

Prerequisites: The current design must be set with the `set_current_design` command.

Defines a pin or port of the current design or a port of a sub-module as a clock enable signal that, when activated, turns off the clock gating on a clock branch.

Usage

```
add_dft_clock_enables pin_port_net_spec -usage {func_en | test_en} [-active_polarity 0 | 1]
```

Description

These clock enable signals are used to suppress clock gating during the functional mode of the operation, and are reused during memory BIST to suppress clock gates fanning out to memories. On a clock gater cell, the clock enable signal with `-usage func_en` corresponds to the pin typically named “en”; it does not correspond to the pin named “te”, which is used to turn off clock gating during the scan shift mode.

Note

The FE/TE pins of the RTL clock gater are automatically added to the `add_dft_clock_enables` list.

If the clock gater is seen to fan out to the reference of a generated clock, the clock gater is turned off by `all_test` such that the generated clock gets its reference clock in all test modes. The following warning is generated during DRC when this happens:

```
// Note: The clock gated pin 'cgand1/rtlcl1_5/Z' fans out to the reference
//       of a generated clock.
//       Disabling it with the DFT signal '~all_test' as its enable is
//       active low.
```

You can use `add_dft_control_points pin -dft_signal_source_name all_test` explicitly on a clock enable pin as long as the use of the `-inverse_dft_signal_source` is specified consistently with the active polarity of the clock enable pin. You can use any DFT signal to point to the clock enable pin as long as its `default_value_in_all_test` option is set to 1.

If you have clock gating cells in your library, you do not need to reference their “en” pins with this command because they are automatically learned. The `report_dft_clock_enables` command reports those automatically if the cell is used at least once in your design. Note that you can also introspect the learned clock gating cells in your design by using the following command:

```
get_modules -filter "cell_type == clock_gating_and || cell_type == clock_gating_or"
```

To see the functional enable port, use:

```
get_ports -of_module $mod -filter "function==func_enable || function==func_enable_inv"
```

To see the test enable port, use:

```
get_ports -of_module $mod -filter "function==test_enable || function==test_enable_inv"
```

You only need to use the `add_dft_clock_enables` command if you have clock gating implemented with logic that does not use clock gating cells such as when you are performing memory BIST insertion in RTL mode. The examples in [Table 3-8](#) illustrate how to define clock enable signals for different scenarios.

The clock enable signals you specify are used during DRC when you issue the `check_design_rules` command in dft context, as long as the “`get_dft_specification_requirements -memory_bist`” command returns “auto” at the time the `check_design_rules` command is issued. Clock enable signals that affect the clocks of memories are automatically identified in DRC and turned off when you run the `process_dft_specification` command in analysis mode.

[Table 3-8](#) illustrates the logic inserted for a clock enable signal with and without a functional source and with both polarities. The source for these examples is either the `nonscan` or the `nonscan_inv` port of a special TDR register. A single TDR is used even if you do more than one insertion pass. Clock gates fanning out to memories tested by memory BIST controllers inserted in a different pass share the special TDR inserted in the first pass.

Refer to the [Patterns/DftControlSettings](#) property to understand how it is automatically controlled during the execution of the `process_patterns_specification` command.

Table 3-8. DFT Logic Inserted for Different `add_dft_clock_enables` Locations

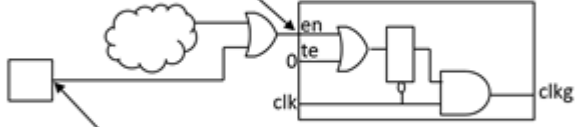

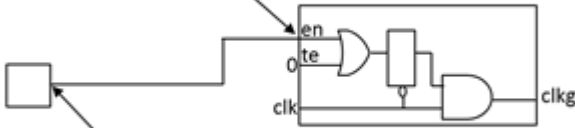

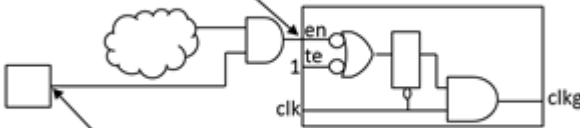

Specification	Resulting DFT
<p>A clock enable with a polarity of 1 and having a functional source prior to the DFT insertion pass</p>	<pre>add_dft_clock_enable u1/cgc1/en -active_polarity 1 -usage func_en</pre>  <p>nonscan_test port of the TDR with tessent_dft_function attribute equal to "scan_tested_instrument_dft_control"</p>
<p>A clock enable with a polarity of 1 and having no functional source (it is tied off or floating) prior to the DFT insertion pass</p>	<pre>add_dft_clock_enable u1/cgc1/en -active_polarity 1 -usage func_en</pre>  <p>nonscan_test port of the TDR with tessent_dft_function attribute equal to "scan_tested_instrument_dft_control"</p>

Table 3-8. DFT Logic Inserted for Different add_dft_clock_enables Locations

Specification	Resulting DFT
A clock enable with a polarity of 0 and having a functional source prior to the DFT insertion pass	<p>add_dft_clock_enable u1/cgc1/en -active_polarity 0 -usage func_en</p>  <p>nonscan_test_inv port of the TDR with tessent_dft_function attribute equal to "scan_tested_instrument_dft_control"</p>
A clock enable with a polarity of 0 and having no functional source (it is tied off or floating) prior to the DFT insertion pass	<p>add_dft_clock_enable u1/cgc1/en -active_polarity 0 -usage func_en</p>  <p>nonscan_test_inv port of the TDR with tessent_dft_function attribute equal to "scan_tested_instrument_dft_control"</p>

Arguments

- pin_port_net_spec**

A required string that specifies a list of one or more names of a pin, port, or net object, or a collection containing one or more pin, port, or net objects. If you have an RTL clock gating module, you can specify it on the port of the clock gating module using the commands shown here:

```
set mods [get_modules my_clock_gate*]
add_dft_clock_enables [get_ports en -of_modules $mods] \
    -usage func_en
```

As previously described, the DRC process automatically identifies the instances that need to be turned off during memory BIST and leaves all other instances untouched. The clock gating cells loaded with the [read_cell_library](#) command are automatically learned and do not need to be referenced by this command.

If the object is a port on the current design and the port connects to the pad_io function of a pad cell, the DFT connection is inserted on the core side of the pad buffer. If the boundary scan cell is already inserted, it is connected on the core side of the boundary scan cell. If there is no boundary scan cell associated to the port, it connects to the from_sji_mux function when it exists, otherwise it connects to the from_pad function.

- usage func_en | test_en**

A required switch and value pair that specifies the usage of the clock enable pins and ports. The func_en value is used for pre-DFT DRC of memory BIST. The test_en value is used for the pre-DFT DRC for logic test.

- `-active_polarity 0 | 1`

An optional switch and value pair that specifies the active polarity of the clock enable signal. When unspecified, the polarity defaults to 1. A polarity of 1 means the clock gating cell is not gating the clock when the clock enable signal is high.

Examples

The following example uses the `add_dft_clock_enables` command to identify the en ports of clock gating modules whose module name starts with “my_clock_gate”, and to define the pin on an instance as a clock enable signal with polarity 0. The source of the clock enable signal is a special TDR that is scan tested with the rest of the functional logic. The [add_dft_control_points](#) command is used to control the select of an existing clock multiplexer; the `add_dft_clock_enables` command is not used for that signal because the clock multiplexer must be controlled in scan test mode too.

The [report_dft_clock_enables](#) command is used in analysis mode with and without the `-post_drc` option to show the specified clock enables and those extracted during DRC. The specified ones can exist on pins or ports of the current design or on ports of any sub-module. During DRC, the clock enables specified on ports of sub-modules are mapped to pins. Only the clock enable signals that affect the memory clocking are kept.

In analysis mode, a read-only wrapper in the tcd partition called “Core(<design_name>)/DftInfo(<design_id>)” contains the ClockEnable signals extracted by DRC. These pins have DFT added to them to turn off the clock gating during memory BIST.

add_dft_clock_mux

Context: dft (with no sub context)

Mode: setup

Prerequisites: The current design must be set.

Instructs the tool to assume the presence of a clock multiplexer during pre-DFT DRC and to insert the multiplexer during DFT insertion as part of the `process_dft_specification` command.

Usage

```
add_dft_clock_mux pin_port_net_spec -test_clock_source test_clock_source_spec  
  [-dft_signal_source_name dft_signal_source_name] [-inverse_dft_signal_source]  
  [-auto_uniquify]
```

Description

Instructs the tool to assume the presence of a clock multiplexer during pre-DFT DRC and to insert the multiplexer during DFT insertion as part of the [process_dft_specification](#) command.

The specified pin, port, or net is intercepted with the 0 input of the multiplexer and the 1 input is connected to the specified `test_clock_source_spec`. The select of the multiplexer is connected to the specified `dft_signal_source_name` with an optional inversion based on the presence of the `-inverse_dft_signal_source` switch.

The default `dft_signal_source_name` value is “all_test” which is a DFT signal that is automatically asserted high during all test modes: those modes based on scan and those that are not. You can also define your own custom `dft_signal_source_names` by using the [register_static_dft_signal_names](#) command.

If you need to insert a custom multiplexer where the select is controlled by an arbitrary source, use the [intercept_connection](#) command with the `-dft_cell_function` option specified as “mux”. Those, however, need to be inserted prior to running DRC.

If you are familiar with the LogicVision Memory Bist flow, a clock multiplexer was specified in ETChecker using the `lv.InternalClockSource -test_clock_source` option. The select was always connected to the `ETClockEnable` signal. In the Tessent Shell flow, the name of the `ETClockEnable` signal is “all_test” because it is a test signal that is activated during all test modes, whether they are based on scan or not.

You no longer get an error if you issue the exact same `add_dft_clock_mux` twice. You only get an error if the second specification has one or more options that are different from the first specification.

Arguments

- ***pin_port_net_spec***

A required string argument that specifies the name of a pin, port, or net of the current design or a collection containing one port, pin, or net object of the current design. The insertion of the multiplexer is permitted on both input and output ports and input and output pins. The select is asserted to the `default_value_in_all_test` value of the `dft_signal_source_name` during pre-DFT DRC, which is 1 when using `all_test` as the DFT signal source name. All combinations of clock path are verified during `extract_icl`. The `default_value_in_all_test` value of the `dft_signal_source_name` is specified with the `register_static_dft_signal_names` command.

- **`-test_clock_source` *test_clock_source_spec***

A required switch-value pair that is used to specify the name of a port, pin, or net of the current design or a collection containing one port, pin, or net object. The specified `test_clock_source_spec` is used to source the 1 input of the multiplexer. The 0 input of the multiplexer remains the original source of the `pin_or_port_spec`.

If the object is a port on the current design and the port connects to the `pad_io` function of a pad cell, the DFT connection is inserted on the core side of the pad buffer. If the boundary scan cell is already inserted, it is connected on the core side of the boundary scan cell. If there is no boundary scan cell associated to the port, it connects to the `from_sji_mux` function when it exists. Otherwise, it connects to the `from_pad` function.

- **`-dft_signal_source_name` *dft_signal_source_name***

An optional switch-value pair that is used to specify a string that defines the name of a DFT signal that sources the select for the multiplexer.

The default `dft_signal_source_name` value is “`all_test`” which is a DFT signal that is automatically asserted high during all test modes: those modes based on scan and those that are not. You can also define your own custom `dft_signal_source_name` using the `register_static_dft_signal_names` command.

- **`-inverse_dft_signal_source`**

An optional Boolean option that specifies an inversion between the source DFT signal and the select port of the multiplexer. The clock multiplexer always needs to reset selecting the 0 input of the multiplexer otherwise the insertion of the multiplexer would affect the functional mode and fail the pre-DFT versus post-DFT formal verification. To satisfy the requirement, you can only refer to a `dft_signal_source_name` that resets to 0 when the `-inverse_dft_signal_source` option is not specified and you can only refer to a `dft_signal_source_name` that resets to 1 when the `-inverse_dft_signal_source` is specified.

- **`-auto_uniquify`**

An optional Boolean option that specifies the parent module of the `pin_port_net_spec` is to be auto-uniquified if seen to be inside an instance of a repeated module. If you do not specify this option, you get an error when running the `check_design_rules` command and you did not specify an `add_dft_clock_mux` command for all instances of the repeated

module. The *test_clock_source_spec* and the *dft_signal_source_name* are permitted to be different for each instance. The error message lists the missing instances making it easy to add them and avoid unification.

Examples

The following example shows the use of three `add_dft_clock_mux` commands. One is to enable the sharing of a common clock source during memory BIST, a technique often used to minimize the number of clock sources needed during manufacturing test. The second one is to enable bypassing of the PLL based on a user-defined DFT signal source name called `pll_bypass`. The third one is used to provide an alternative source for the reference of the PLL based on a user-defined DFT signal source name called `alt_ref`. Notice that during insertion the interception for all multiplexers is done first and then the connections for the test clock sources are performed. This makes sure the test clock source of the green multiplexer is not intercepted by the red interception. Notice that it is not permitted to insert a clock multiplexer in the middle of a balanced clock tree. This is why this example has two declared branch clocks to denote the base of the balanced clock tree feeding the memories. The inserted clock multiplexers can only fanout to the reference of generated clocks and to branch clocks but not to memories or scannable flip-flops directly. If you want to insert a multiplexer without declaring a branch clock, you have to insert it in your design (either manually or with a custom insertion script using the [intercept_connection](#) command). You leave the select tied off and then point to it using the [add_dft_control_points](#) to make it controllable by IJTAG.

Note how the `DftSpecification` contains a `Tdr` wrapper having an Attribute `tessent_dft_function` set to `scan_resource_instrument_dft_control`. You cannot delete or modify this `Tdr` wrapper when you use the `add_dft_clock_mux` or the [add_dft_control_points](#) commands.

add_dft_control_points

Context: dft (with no sub context)

Mode: setup

Prerequisites: The current design must be set.

Instructs the tool to assume the presence of the DFT control logic during pre-DFT design rule checking, and to insert the controlling logic during DFT insertion as part of the `process_dft_specification` command.

Usage

```
add_dft_control_points pin_port_net_spec [-type type] [-inverse_dft_signal_source]
  [-dft_signal_source_name dft_signal_source_name] [-ignore_existing_sources]
  [-auto_uniquify] [-allow_editing_below_ijtag_instances]
```

Description

Instructs the tool to assume the presence of the DFT control logic during pre-DFT design rule checking, and to insert the controlling logic during DFT insertion as part of the `process_dft_specification` command.

For DFT control points of type “static_dft_control”, when the specified object is a port or an output pin, and when the specified object is an input pin or a net with a functional source (that is, its `has_functional_source` `Pin` or `Net` attribute is true), it is intercepted with the 0 input of a multiplexer and the 1 input gets connected to the static DFT signal source location. The source is inverted when the `-inverse_dft_signal_source` option is specified. The select of the multiplexer is connected to the “all_test” DFT signal. The logic is a simple OR gate or AND gate when the `dft_signal_source_name` is specified as “all_test”. (To obtain this simple OR/AND logic for a signal name other than “all_test,” use the `register_static_dft_signal_names` command to define the signal to be of type “logic_test_control”.) When the specified pin or port has no functional source (that is, its `has_functional_source` attribute is false), it gets directly connected to the DFT signal source with an optional inversion. Refer to [Table 3-9](#) for illustrations of the inserted logic and connections. If the specified node is tied but the value does not match the reset value of the DFT signal, you get an error unless you use the `-ignore_existing_sources` option.

The default `dft_signal_source_name` value is “all_test”, which is a DFT signal that is automatically asserted high during all test modes: modes based on scan and those that are not. Use `report_dft_signal_names` to find the built-in static DFT signals. You can also define your own custom DFT signal names using the `register_static_dft_signal_names` command. For more information about customizing `dft_signal_source_name` and its usage, refer to the `register_static_dft_signal_names` command section.

If you need to insert a custom gate where the second data input and the select input is controlled by arbitrary sources, use the `intercept_connection` command with the `-dft_cell_function` option specified as “mux”, “and” or “or”. Those, however, needs to be inserted prior to running DRC.

If you are familiar with the LogicVision MemoryBIST flow, a control point was specified in ETChecker using the *lv.ETClockEnable* and the *lv.InjectControl -type UserBit* properties. In the Tessent Shell flow, the ETClockEnable signal is now called “all_test” because it is a test signal that is activated during all test modes, whether they are based on scan or not. A UserBit is now a user-registered DFT signal name.

For DFT control point of type “dynamic_dft_control”, the specified signal is always directly connected to the specified node. You get an error if the specified node has a functional source (that is, its has_functional_source attribute is true) or if it is tied to a 1 unless you use the -ignore_existing_sources switch. In such a case, the existing source is simply replaced by the dynamic DFT signal source.

You no longer get an error if you issue the exact same add_dft_control_point twice. You only get an error if the second specification has one or more options that are different from the first specification.

In a hierarchical flow, if you add any dynamic DFT signals in the current design and the current design instantiates some lower designs in which you had added dynamic DFT signals sourced by ports, an “add_dft_control_point -type dynamic_dft_signal” command is inferred to connect them if their "has_functional_source" attribute returns false. When this happens, the tool displays a note similar to the following:

check_design_rules

```
// Note: Inferred 5 'add_dft_control_points <pin>
//       -type dynamic_dft_control' commands to connect the dynamic DFT
//       signals pins on the child block instances. Use
//       report_dft_control_points to see them.
```

If the scan_en dynamic DFT signal was not added yet and the scan_en DFT signals are seen to be floating at the input of a sub designs, they are tied low as part of running the [process_dft_specification](#) command such that the functional and the non-scan test modes work. The scan_en is later connected to the DFT signal “scan_en” once you add it in the current design.

Table 3-9. DFT Logic for add_dft_control_points Nodes

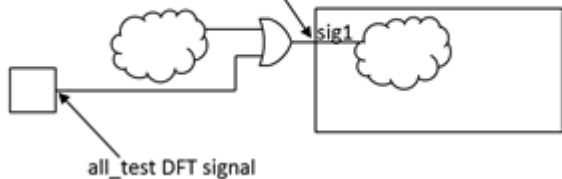

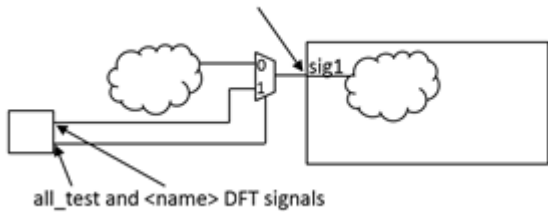

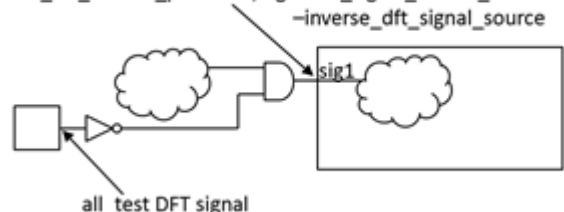

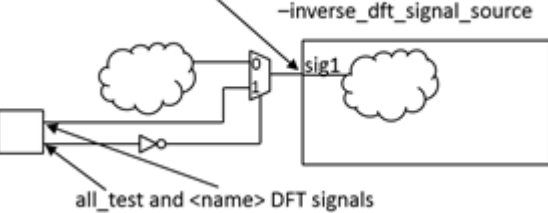

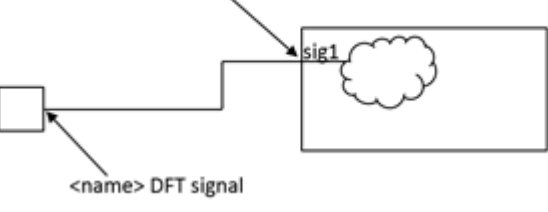

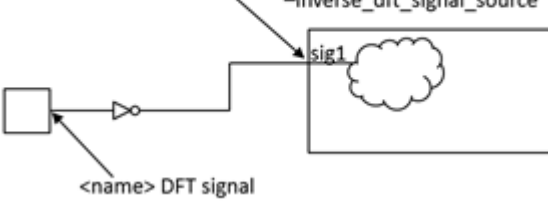

Specification	Resulting DFT
<p>A dft control point with DFT signal source equal to "all_test" or another DFT signal source that is of usage "Logic Test Control". The object has a functional source prior to the DFT insertion.</p>	<p>add_dft_control_points u1/sig1 -dft_signal_source_name all_test</p>  <p>The diagram illustrates the resulting DFT logic. It shows a logic block with two inputs and one output. The first input is labeled 'all_test DFT signal'. The second input is connected to an AND gate. The output of the AND gate is labeled 'sig1'. The output of the logic block is also labeled 'sig1'. Above the diagram, the command 'add_dft_control_points u1/sig1 -dft_signal_source_name all_test' is shown.</p>

Table 3-9. DFT Logic for add_dft_control_points Nodes (cont.)

Specification	Resulting DFT
<p>A dft control point with control source equal to a name other than "all_test" that is also of usage "Global DFT Control". The object has a functional source prior to the DFT insertion.</p>	<p><code>add_dft_control_points u1/sig1 -dft_signal_source_name <name></code></p> 
<p>A dft control point with an inverted control source equal to "all_test". The object has a functional source prior to the DFT insertion.</p>	<p><code>add_dft_control_points u1/sig1 -dft_signal_source_name all_test -inverse_dft_signal_source</code></p> 
<p>A dft control point with an inverted control source equal to a name other than "all_test". The object has a functional source prior to the DFT insertion.</p>	<p><code>add_dft_control_points u1/sig1 -dft_signal_source_name <name> -inverse_dft_signal_source</code></p> 
<p>A dft control point with any DFT signal source name. The object has no functional source (it is tied or floating) prior to the DFT insertion.</p>	<p><code>add_dft_control_points u1/sig1 -dft_signal_source_name <name></code></p> 
<p>A dft control point with any inverted DFT signal source name. The object has no functional source (it is tied or floating) prior to the DFT insertion.</p>	<p><code>add_dft_control_points u1/sig1 -dft_signal_source_name <name> -inverse_dft_signal_source</code></p> 

Arguments

- **pin_port_net_spec**

A required string that specifies a list of one or more names of pin, port, or net object, or a collection containing one or more pin, port, or net objects. The control point is permitted to be specified on both input and output ports and input and output pins. The DFT signal source name “all_test” is asserted active during pre-DFT Memory BIST DRC. The other DFT signal source names are asserted to their respective “default_value_in_all_test” specified when registering them. Refer to the [register_static_dft_signal_names](#) command for more information about the behavior of the DFT signals.

If the object is a port on the current design and the port connects to the pad_io function of a pad cell, the DFT connection is inserted on the core side of the pad buffer. If the boundary scan cell is already inserted, it is connected on the core side of the boundary scan cell. If there is no boundary scan cell associated to the port, it connects to the from_sji_mux function when it exists. Otherwise, it connects to the from_pad function.

- -type [static_dft_control](#) | [async_set_reset](#) | [dynamic_dft_control](#)

An optional switch-value pair that specifies the kind of DFT control to add. For DFT control point of type [static_dft_control](#), the specified node is connected or intercepted with a multiplexer by the specified DFT signal as shown in [Table 3-9](#). For DFT control of type [dynamic_dft_control](#), the specified node is connected to the specified DFT signal.

When type is set to [async_set_reset](#), the specified node is checked by [DFT_C9](#) and if seen to source asynchronous set or reset pins of one or more scannable flip-flops, the common off value is determined, and an OR gate or an AND gate is inserted to enable turning off the asynchronous set and reset pins during shift mode. An OR gate is used when the active polarity is determined to be 0 and an AND gate is used when the active polarity is determined to be 1. The other input of the GATE is connected to the DFT signal “[async_set_reset_dynamic_disable](#)”. Refer to [Table 3-13](#) on page 215 in the [add_dft_signals](#) command description for more information about this DFT signal. By default, [DFT_C9](#) infers the [async_set_reset](#) DFT control points on the nodes found to be controlling sources of asynchronous set or reset pins. Refer to “[set_drc_handling dft_c9 - auto_fix](#)” command description to know how to turn off the auto fixes.

If you have issued the `add_dft_control_point -type async_set_reset` command and [set_dft_specification_requirements -logic_test](#) is off, then issuing the [check_design_rules](#) command produces the following error:

```
// Error: You can't have 'add_dft_signals -type async_set_reset'  
// when 'set_dft_specification_requirements -logic_test' is 'off'.  
// Unless DFT_C9 runs, the active polarity of the set or reset  
// nodes cannot be determined.  
// Either add '-logic_test on' to your  
// set_dft_specification_requirements settings or issue  
// delete_dft_control_points {{rst} {ram1/AR[1]}}
```

- -inverse_dft_signal_source

An optional Boolean option that specifies an inversion between the DFT signal specified by the `-dft_signal_source_name` option and the *pin_port_net_spec*.

- -dft_signal_source_name *dft_signal_source_name*

An optional switch-value pair that is used to specify a string that defines the name of DFT signal that is to source the *pin_port_net_spec* during test modes.

The default *dft_signal_source_name* value is “all_test”, which is a DFT signal that is automatically asserted high during all test modes: modes based on scan and those that are not. You can also define your own custom *dft_signal_source_names* using the [register_static_dft_signal_names](#) command.

- -ignore_existing_sources

An optional Boolean option that is used to suppress the error that is normally generated in those two situations. For DFT signal of type “static_dft_control”, you get an error if the specified node is tied and the tie value is not consistent with the reset value of the DFT signal taking into account if the source is inverted or not. Specifying this switch suppresses the error and enables replacing the tie value with the connection from the DFT signal. Realize that suppressing this error causes the node to have a different value in functional mode as compared to before the connection was made.

For DFT signal of type “dynamic_dft_control”, you get an error if the specified node is tied and the tie value is not consistent with the reset value of the DFT signal taking into account if the source is inverted or not. You also get an error if the node already has a functional source. Specifying this switch suppresses the error and enables replacing the tie value or the functional source with the connection from the DFT signal. Realize that suppressing this error causes the node to have a different value in functional mode as compared to before the connection was made.

- -auto_uniquify

An optional Boolean option that specifies the parent module of the *pin_port_net_spec* is to be auto-uniquified if seen to be inside an instance of a repeated module. If you do not specify this option, you get an error when running the [check_design_rules](#) command and you did not specify an `add_dft_control_points` command for all instances of the repeated module. The *dft_signal_source_name* is permitted to be different for each instance. The error message lists the missing instances making it easy to add them and avoid unification.

- -allow_editing_below_ijtag_instances

An optional Boolean switch that enables you to point to a pin that is below a module that has a matched ICL module. By default, you are not permitted to point to a pin that is inside an instance with its `is_hard_module` or `created_by_synthesis` attribute set to true. When `-type` is set to `static_dft_control`, you are also not permitted to point to a pin that is below a module that has a matched ICL module because those DFT inject points can affect the ICL view of the module. If you are sure that the control point does not affect the ICL view, use this switch to relax the check. Otherwise, go back to a step prior to when the ICL was created to insert the DFT control point.

Examples

This example uses the `add_dft_control_points` to inject a control multiplexer on the select of an existing clock multiplexer. The inserted logic is illustrated in [Figure 3-5](#). The output port “all_test” on the TDR is automatically asserted high at the beginning of the patterns created using [process_patterns_specification](#). You can decide to activate the PLL bypass mode by setting the `pll_bypass` port active using the [Patterns/DftControlSettings](#) wrapper. If you have a programmable PLL with a built-in `bypass_en` port and ports to control the multiplication factor, you can use this command to control those ports. A more automated way is to create an ICL model for the PLL describing the `DataInPorts` of the PLL. The [create_dft_specification](#) command automatically hooks them up to the iJTAG network. You can then use a [ProcedureStep](#) to program your PLL. You must use the `add_dft_control_points` when the injected values are needed by the pre-DFT DRC.

Note how the `DftSpecification` contains a `Tdr` wrapper having an `Attribute tessent_dft_function` set to `scan_resource_instrument_dft_control`. You cannot delete or modify this `Tdr` wrapper when you use the [add_dft_clock_mux](#) or the `add_dft_control_points` commands.

add_dft_modal_connections

Context: dft

Mode: setup

A command used to insert modal connections from specified output data source nodes or to input data destination nodes typically used to connect the EDT channel input and output pins from multiple cores to and from a limited set of input and output ports.

Usage

```
add_dft_modal_connections
  {-ports port_spec | -auxiliary_data_pins pin_spec [-auxiliary_enable_pins pin_spec] }
  {-output_data_source_nodes port_pin_spec
  | -input_data_destination_nodes port_pin_spec }
  {-enable_dft_signal dft_signal_name | -enable_source_node port_pin_spec }
  [-inverse_enable]
  [-pipeline_stages pipeline_stages | -nonscan]
  [-output_retiming {on | off}]
```

Description

Use this command to insert modal connections from specified output data source nodes or to input data destination nodes. Once the tool adds all modal connections, it analyzes them and inserts appropriate multiplexing and pipelining logic to implement the specification. You can use this command to connect the EDT channel input and output pins from multiple cores to and from a limited set of input and output ports. Use the [report_dft_modal_connections](#) command to find the cumulative effect of your specified `add_dft_modal_connections` commands and understand the inserted multiplexing logic.

Typically, you have a limited number of top-level ports that you can use to provide data to the EDT channel inputs and observe the EDT channel outputs. This prevents you from running all EDT cores in parallel. Instead, you need to use sets of cores to create multiple top-level access modes so that you do not exceed the top-level resources available in your chip.

The `add_dft_modal_connections` command is very flexible and enables you to insert the necessary multiplexing and pipelining logic automatically. [Figure 3-6](#) shows that you require multiplexing logic when you specify multiple modal connections on the same output port. The blue logic represents the auxiliary output logic present on the output port. The auxiliary output logic must permit multiplexing between the auxiliary data out values and the functional values and enable the pad output buffers. You can use the [BoundaryScan](#) wrapper of the [DftSpecification](#) to equip the top-level ports with auxiliary input and output logic. The actual logic inserted is more complicated than the blue logic shown in [Figure 3-6](#) because Boundary Scan also needs control of the ports, and you do not want to cascade two multiplexers along the functional data path. Refer to [Figure 10-36](#) on page 3886 in the [AuxiliaryInputOutputPorts](#) section of the [BoundaryScan](#) wrapper section for a precise description of this logic.

Note

 The circuitry described next is included in modules handling one bit at a time. The tool instantiates these modules in the parent instance of the auxiliary data pin they handle. If you used the [BoundaryScan AuxiliaryInputOutputPorts](#) wrapper to insert your auxiliary data logic, the auxiliary data logic is located in the logical grouping module associated with a given port. You have the flexibility to place the logical grouping modules where you want. The modal connection modules follow the logical grouping module and are instantiated in the same parent instance module. If you use the `-auxiliary_data_pins` option, the modules are instantiated in the parent instance of those pins. For the modules sometimes created at the destination of auxiliary input connections and illustrated in [Figure 3-8](#), the parent instance of the “`input_data_destination_nodes`” is where they are instantiated.

Note

 The tool creates modal connection modules to handle one bit at a time. The same module is instantiated multiple times if multiple connections have the same muxing and pipelining requirement unless the [reuse_modules_when_possible](#) property found in the [DftSpecification](#) wrapper defaults is off or is set to off, in which case the tool creates one module per bit even if the content is identical to others.

The multiplexing is achieved by ANDing each data source with its associated enable source and ORing the AND gates together. This kind of multiplexing is very efficient for routing as there is no select priority logic, and the layout tool can split the OR gate to minimize the congestion. The enable sources are also ORed together to activate the auxiliary output data path. The auxiliary data output enable signal is gated by `scan_en`. This permits the functional output logic to be observable during the capture cycles either by the boundary scan cell if you are using the boundary scan during scan test (refer to the [max_segment_length_for_logictest](#) property in the [BoundaryScan](#) wrapper to enable that) or by the PO itself.

Figure 3-6. Multiplexing and Pipelining Logic for Output Connections

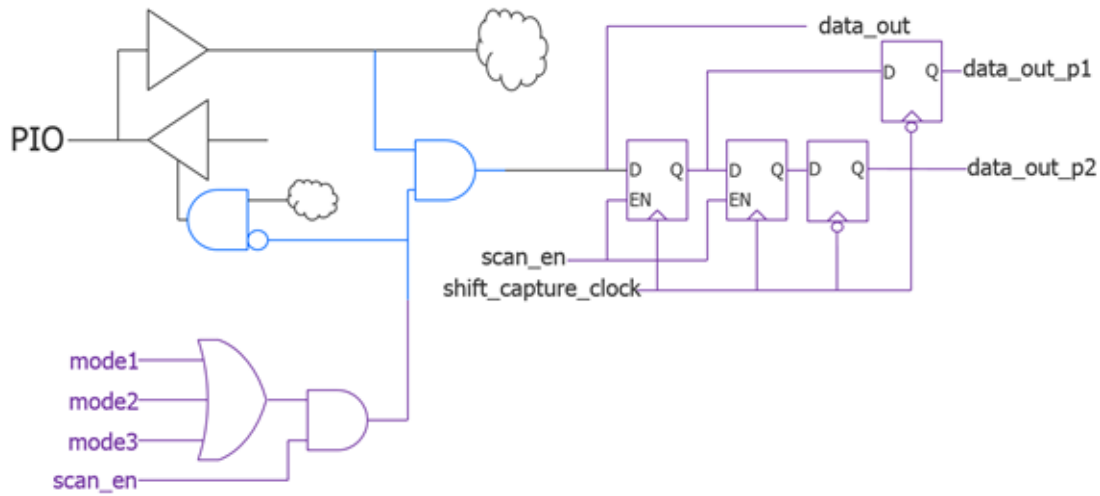

(Output data muxing and pipelining logic added by add_dft_modal_connections)
 (Auxiliary Data muxing such as the one added by Tessent Boundary Scan)

Multiplexing logic is not needed at the source for the auxiliary input data connections. As shown in [Figure 3-7](#), the enable sources still need to be ORed together to drive the auxiliary input enable pin of the port. The auxiliary input enable is used to gate off the auxiliary data so that it does not follow the port value during functional mode. When the port is an inout port, the enable is also used to turn off the output driver so that the port can be used to supply input data. Finally, if pipelining was requested, the auxiliary data is pipelined and the re-timed pipelined sources are used to make the connections to the specified destinations.

[Figure 3-8](#) shows that multiplexing logic may be required at the destination nodes. For example, if an ELT core is re-used in multiple configurations, the edt_channel_in ports may have different sources in different modes. The circuit shown in [Figure 3-8](#) is used to implement the necessary multiplexing. When such multiplexing is required, the [report_dft_modal_connections](#) command includes an “Input destinations” section showing the multiplexing on the destination pins.

Figure 3-7. Enable Logic and Pipelining for Input Connections

(Input data enabling and pipelining logic added by add_dft_modal_connections)

(Auxiliary Data enabling such as the one added by Tessent Boundary Scan)

Figure 3-8. Multiplexing for Destinations of Modal Connections

(Input data muxing added by add_dft_modal_connections)

The pipelining flip-flops are clocked using the shift_capture_clock that you define the source using the “[add_dft_signals](#) shift_capture_clock” command. If you are using the add_dft_modal_connections command to provide source or observation of data coming from non-scan test modes, you specify the -nonscan switch, and you do not specify the -pipeline_stages switch.

Output connections sharing the same destination port share the same output retiming setting. When you turn off output retiming for at least one connection, it is turned off for all in the group. The tool reports a warning in this case.

Note

 The `report_dft_modal_connections` command reports “(not retimed - forced)” for modes with an inferred output retiming setting.

Maximizing the Shift Rate of the logictest Mode

The shift clock rate of the scan-based test modes is often limited by the loop timing arc (illustrated by the magenta arrow in [Figure 3-9](#)) starting from the shift clock input, propagating through the clock tree to reach the last flop on the chain and exiting the chip through an output buffer. The majority of the delay is spent in the clock tree. To reduce this timing arc, you can use a few pipelining flip-flops in series for the scan-out path and control the clock tree synthesis tool to place the last flop as close as possible to the base of the clock tree. If the clock tree delay is larger than one clock period, use a clock point that is mid-point along the clock tree for the middle pipelining flop. You then have a full cycle minus the clock delay difference between the first and the middle pipelining flip-flop (illustrated by the green arcs), and again a full cycle minus the clock delay difference between the middle and the last pipelining flip-flop (illustrated by the yellow arcs). The `add_dft_modal_connections` command enables you to insert up to five pipelining flops in series. You then need to provide instruction to your Clock tree synthesis to not balance the clock inputs to the last stages in order to enable stepping down toward the output port. Pipelining is typically not needed on the input direction because the clock path delay largely compensates for the delay in the data paths (illustrated by the blue arcs).

Figure 3-9. Timing Arcs for Scan In and Out Paths

Arguments

- **-ports *port_spec***

A switch used to specify a list of one or more port names or a collection of one or more port objects that are to be used as data source or destination. The direction of the data connection is controlled by the use of one of the mandatory and mutually exclusive `-output_data_source_nodes` and `-input_data_destination_nodes` switches. When the `-output_data_source_nodes` switch is used, the specified ports must either be existing or to-be-created output ports or existing output or inout ports equipped with auxiliary data logic. When design level, as specified by the `set_design_level` command is "chip", ports cannot be created and must already be connected to a pad equipped with auxiliary data output logic. At the physical or sub-block level, you may specify to-be-created ports or existing ports having no existing functional sources. Refer to the [AuxiliaryInputOutputPorts](#) section of the [BoundaryScan](#) or [EmbeddedBoundaryScan](#) sections to learn how to automatically equip ports with auxiliary input or output data logic.

When you use Tessent Boundary Scan to insert the auxiliary input and output data logic, the location of the auxiliary data and enable pins is described in the [Instrument Dictionary](#) created during boundary scan insertion. You can then use the `-ports` switch to point to the ports and the mapping to the auxiliary data and enable pins is done automatically. If you

implemented the auxiliary data logic manually or with a third party tool, you have two options. You can either describe the mapping between the top level ports and the auxiliary data pins using a Tcl dictionary called “::auxiliary_data_dict” or by pointing explicitly to the auxiliary data and enable pins using the `-auxiliary_data_pins/-auxiliary_enable_pins` switches for each invocation of the `add_dft_modal_connections` commands.

The format of the “::auxiliary_data_dict” dictionary is the following:

```
<port_name> {
  auxiliary_output_pin      <pin_name>
  auxiliary_output_enable_pin <pin_name>
  auxiliary_input_pin       <pin_name>
  auxiliary_input_enable_pin <pin_name>
}
... #repeat for all ports
```

You can use the Tcl “dict” command to populate this dictionary once so that you can then make your DFT modal connection using the `-ports` switch instead of having to explicitly point to the auxiliary data and enable pins explicitly each time. Ex:

```
dict set ::auxiliary_data_dict gpio[1] auxiliary_input_pin u1/aux_in
```

The enable pin entries in the dictionary are optional. If you do not list them, the `add_dft_modal_connections` command only performs the data multiplexing and assumes you have already handled the enabling of the auxiliary data path.

- **`-auxiliary_data_pins` *pin_spec***

A switch used to specify the location of the auxiliary input or output data pins. The *pin_spec* value is a list of one or more names of pin objects or a collection containing one or more pin objects. It refers to auxiliary input data pins when the `-input_data_destination_nodes` switch is used. It refers to auxiliary output data pins when the `-output_data_source_nodes` switch is used. If you have created the auxiliary data logic with Tessent Boundary Scan using the [AuxiliaryInputOutputPorts](#) wrapper of the [BoundaryScan](#) or the [EmbeddedBoundaryScan](#) wrappers, or if you have described your auxiliary data and enable pins in the Tcl dictionary “::auxiliary_data_dict” described above in the `-ports` switch section, you do not need to use the `-auxiliary_data_pins` switch. Instead, you use the `-ports` switch and the mapping to the auxiliary data and enable pins are extracted automatically.

If you have the already connected the auxiliary enable pins and you only want the `add_dft_modal_connections` command to handle the data muxing, point to the auxiliary data pin using the `-auxiliary_data_pins` switch and omit specifying the `-auxiliary_enable_pins` switch.

- **`-auxiliary_enable_pins` *pin_spec***

A switch used to specify the location of the auxiliary input or output enable pins. The *pin_spec* value is a list of one or more names of pin objects or a collection containing one or more pin objects. It refers to auxiliary input enable pins when the `-input_data_destination_nodes` switch is used. It refers to auxiliary output enable pins when the `-output_data_source_nodes` switch is used. Refer to the description of the

-auxiliary_data_pins switch above to know when you need to use it and how the location of the auxiliary enable pins are inferred automatically when using the -ports switch.

- **-output_data_source_nodes *port_pin_spec***

A switch that is mutually exclusive with the -input_data_destination_nodes switch but required when the -input_data_destination_nodes switch is not specified. You use this switch to specify a list of one or more names of port or pin objects or to specify a collection containing one or more port or pin objects that sources the modal connection. The number of pins or ports specified in the *port_pin_spec* must match the number of elements specified with the -ports or -auxiliary_data_pins switches. If the port or the auxiliary output pin is already connected to the source needed in the given mode, use the symbol “*” as the *port_pin_spec* value, and the current source is preserved for that mode. Refer to [Example 1](#) for an example of its usage.

Note

 When you specify the -output_data_source_nodes switch and the -output_retiming switch is set to off, the tool removes the negative-edge retiming register in all modal multiplexer instances connected to the specified source nodes.

- **-input_data_destination_nodes *port_pin_spec***

A switch that is mutually exclusive with the -output_data_source_nodes switch but required when the -output_data_source_nodes switch is not specified. It is used to specify a list of one or more names of port or pin objects or to specify a collection containing one or more port or pin objects that are the destination of the modal connections. The number of pins or ports specified in the *port_pin_spec* must match the number of elements specified with the -ports or -auxiliary_data_pins switches. If the port or the auxiliary input pin is already connected to the needed destination in the given mode, use the symbol “*” as the *port_pin_spec* value and the current destination is preserved for that mode even if pipelining is inserted. Refer to [Example 1](#) for an example of its usage.

Note

 When you specify the -input_data_destination_nodes switch and the -output_retiming switch is set to off, the tool connects the specified destination node to the data pin driven by a non-retimed pipeline located in a Modal Data In instance.

- **-enable_dft_signal *dft_signal_name***

A switch that is mutually exclusive with the -enable_source_node switch but required when the -enable_source_node switch is not specified. It specifies the name of a DFT signal that is to serve as the source to enable the modal connection. When the -nonscan switch is not specified, the DFT signal must be of type “scan_mode”. When the -noscan switch is used, the DFT signal must be of type “global_dft_control”. Refer to the [add_dft_signals](#) command for more information about DFT signal types. If the specified *dft_signal_name* is not already present or added, it is added automatically if it is a registered DFT signal name. Use [report_dft_signals](#) to find the list of registered DFT signal names. Refer to the [register_static_dft_signal_names](#) command description to register your own.

- **-enable_source_node *port_pin_spec***

A switch that is mutually exclusive with the `-enable_dft_signal` switch but required when the `-enable_dft_signal` switch is not specified. It specifies the name of a pin or port object or a collection containing a port or pin object. If you do not use a DFT signal to control the modal connections, you are responsible to provide the appropriate `test_setup` proc when using the modal connections during scan or `scan_retargeting` DRC.

If you used a DFT signal instead, enabling the mode during the DRC is as easy as calling the [set_static_dft_signal_values](#) command.

- **-inverse_enable**

An optional switch that is used to specify that the modal connection is to be enabled when the specified enable DFT signal or source node is low instead of high. You cannot use this option when making a connection involving an `auxiliary_enable_pin` because all auxiliary enable pins must be driven low during functional mode; otherwise, the functional mode will be broken. Also, you can only use this switch when there is only one other modal connection made to the port and this other connection is enabled by the same enable source but without the inversion.

- **-pipeline_stages *pipeline_stages***

An optional switch used to specify an integer to request between 1 to 5 levels of pipelining stages along the modal DFT connection. If you broadcast one input port to multiple destinations in a given mode, the number of pipelining stages must be equal in all broadcasted connections.

- **-nonscan**

An optional switch used to specify that the modal connection is for a non scan-based test mode. The DFT signal `scan_en` is not used to gate off the auxiliary enable pin when those modes are used.

- **-output_retiming on | off**

An optional switch to specify if the generated modal connection logic has a negative-edge flip-flop at the end of its pipeline. The default is on.

Note

 The `-output_retiming` switch has no effect when `-pipeline_stages` is not specified or set to 0. The tool reports a warning when you use the `-output_retiming` switch without `-pipeline_stages`.

```
// Warning: -output_retiming switch has no effect when  
-pipeline_stages is not specified or set to 0.
```

Examples

Example 1

The following example has two identical instances of a module called “corea”. The gpio[3:0] were equipped with auxiliary input and output logic during Boundary Scan implementation using this syntax:

```
set spec [create_dft_spec]
read_config_data -in ${spec}/BoundaryScan -from_string {
  AuxiliaryInputOutputPorts {
    auxiliary_input_ports : gpio[1:0];
    auxiliary_output_ports : gpio[3:2];
  }
}
```

When it is time to insert the top level EDT controller, the channels are connected normally to the auxiliary input and output pins of the ports. The get_auxiliary_pins command is used to get the auxiliary data pins created by the Boundary Scan step. The use of the “*” symbol in the edt mode commands specifies to preserve the connections that were done when the top level EDT controller was instantiated. The retargeting1 and retargeting2 modes each retarget the edt mode corea_i1 and corea_i2 through the gpio[2:0] ports. The retargeting3 mode broadcasts the gpio[1:0] auxiliary data inputs to both instances and uses gpio[2] for the EDT output of corea_i1 and gpio[3] for corea_i2.

```
set mode edt_mode
add_dft_modal_connections -ports gpio[1:0] \
  -input_data_destination_nodes * \
  -enable_dft_signal $mode
add_dft_modal_connections -ports gpio[2] \
  -output_data_source_nodes * \
  -enable_dft_signal $mode

set mode retargeting1_mode
add_dft_modal_connections -ports gpio[1:0] \
  -input_data_destination_nodes corea_i1/edt_channels_in[1:0] \
  -enable_dft_signal $mode
add_dft_modal_connections -ports gpio[2] \
  -output_data_source_nodes corea_i1/edt_channels_out[0] \
  -enable_dft_signal $mode

set mode retargeting2_mode
add_dft_modal_connections -ports gpio[1:0] \
  -input_data_destination_nodes corea_i2/edt_channels_in[1:0] \
  -enable_dft_signal $mode
add_dft_modal_connections -ports gpio[2] \
  -output_data_source_nodes corea_i2/edt_channels_out[0] \
  -enable_dft_signal $mode
```

```

set mode retargeting3_mode
add_dft_modal_connections -ports gpio[1:0] \
  -input_data_destination_nodes corea_i1/edt_channels_in[1:0] \
  -enable_dft_signal $mode
add_dft_modal_connections -ports gpio[2] \
  -output_data_source_nodes corea_i1/edt_channels_out[0] \
  -enable_dft_signal $mode
add_dft_modal_connections -ports gpio[1:0] \
  -input_data_destination_nodes corea_i2/edt_channels_in[1:0] \
  -enable_dft_signal $mode
add_dft_modal_connections -ports gpio[3] \
  -output_data_source_nodes corea_i2/edt_channels_out[0] \
  -enable_dft_signal $mode

check_design_rules
set spec [create_dft_spec -sri_sib_list {occ edt}]
read_config_data -in_wrapper $spec -from_string {
  Occ {
    ijtag_host_interface : Sib(occ);
    Controller(clka) {
      clock_intercept_node : clka_buf/A;
    }
  }
  Edt {
    ijtag_host_interface : Sib(edt);
    Controller(c1) {
      longest_chain_range      : 10, 50;
      scan_chain_count         : 40;
      input_channel_count      : 2;
      output_channel_count     : 1;
      connect_bscan_segments_to_lsb_chains : on;
      Connections {
        EdtChannelsIn(1) {
        }
        EdtChannelsIn(2) {
        }
        EdtChannelsOut(1) {
          Pipelinestage {
          }
        }
      }
    }
  }
}

set_config_value port_pin_name \
-in $spec/Edt/Controller(c1)/Connections/EdtChannelsIn(1) \
[get_single_name [get_auxiliary_pins gpio[0] -direction input]]

set_config_value port_pin_name \
-in $spec/Edt/Controller(c1)/Connections/EdtChannelsIn(2) \
[get_single_name [get_auxiliary_pins gpio[1] -direction input]]

set_config_value port_pin_name \
-in $spec/Edt/Controller(c1)/Connections/EdtChannelsOut(1) \
[get_single_name [get_auxiliary_pins gpio[2] -direction output]]

```

Following is the output created by the report_dft_modal_connections when running on the above example:

```
DFT Modal Connections

```

Example 2

The following example shows three input modal connections connected to the same input; one has the output retiming turned off.

```

// command: add_dft_modal_connections -ports gpio[7] \
      -input_data_destination_nodes sub1/ib1[0] \
      -enable_dft_signal retargeting1_mode \
      -pipeline_stages 2
// command: add_dft_modal_connections -ports gpio[7] \
      -input_data_destination_nodes sub1/ib1[1] \
      -enable_dft_signal retargeting2_mode \
      -pipeline_stages 2 -output_retiming off
// command: add_dft_modal_connections -ports gpio[7] \
      -input_data_destination_nodes sub1/ib1[2] \
      -enable_dft_signal retargeting3_mode \
      -pipeline_stages 3

```

add_dft_signals

Context: dft

Mode: setup

Adds static and dynamic DFT signals used to control various aspect of the DFT logic.

Usage

```
add_dft_signals {name ...}  
  [-source_nodes pin_port_spec [-make_ijtag_port]  
  | -create_from_other_signals [-parent_instance parent_instance]  
  | -leaf_instance_name leaf_instance_name]  
  | -create_with_tdr [-disable_for_functional_safety {on | off | auto}]]  
  [-add_hold_scan_cell {on | off | auto} [-hold_scan_cell_disable dft_signal]]
```

Description

A command used to request the addition of static and dynamic DFT signals used to control various aspect of the DFT logic. There are several pre-registered DFT signals that you can use to control the circuit during its multiple test modes.

- [Table 3-10](#), [Table 3-11](#), and [Table 3-12](#) list the pre-registered static DFT signals.
- [Table 3-13](#) on page 215 lists the pre-registered dynamic DFT signals.

Use the [report_dft_signal_names](#) command to report the list of registered DFT signals. Use the [register_static_dft_signal_names](#) command to register additional signals.

The static DFT signals are separated into the following groups:

- **global_dft_control** — Contains signals used to control global resources such as clocking and power management circuitry.
- **logic_test_control** — Defines the signals used to configure various aspect of the circuit during logic test modes.
- **scan_mode** — Defines the signals used to configure the scan chains into the various scan configurations during logic test modes. When using scan_mode signals (*edt_mode*, *multi_mode*, and so on), only one mode is active at a time.

The *logic_test_control* signals include *ltest_en*, which is the signal used to place the circuit in logic test mode. This signal is systematically set to 1 when running any logic test mode. The *int_ltest_en* and the *ext_ltest_en* signals are used to place the circuit in internal or external mode. A scan mode that includes both the wrapper and internal scan chains of a core can be operated in internal mode by keeping *int_ltest_en* to 1. The same scan chain configuration can be turned into an unwrapped mode by forcing *int_ltest_en* to 0. Refer to the [set_static_dft_signal_values](#) command for more information about how to set them.

The `memory_bypass_en` signal is another example of a `logic_test_control` signal. When set to 1, the tool runs ATPG on a given scan mode with the memory bypass logic enabled. This configuration is used to cover the majority of the faults. When set to a 0, the tool keeps the memory active during scan test to cover the memory port faults using multi-load patterns.

The tables below describe each signal and when to use them.

DFT Signals and IJTAG

By default, the static DFT signals are implemented with a special IJTAG TDR. When you specify a static DFT signal, the tool automatically creates the signal on a TDR. If the DFT signal was added in a previous insertion pass, it is automatically reused.

When the `Sib(sti)` is already present and its input that are to be connected to a DFT signal still have the `has_functional_source` attribute = 0, then the tool makes the port connections as the signals are added using this command. Refer to [Figure 10-14](#) on page 3761 and [Figure 10-15](#) on page 3762 for more information about the `Sib(sti)` and its interaction with logic test. Refer to “[How the IjtagNetwork Specification is Created](#)” on page 531 for further information on `Sib(sti)`.

If you have your own IJTAG node to source these signals, you can add attributes in the `DataOutPort` wrapper of its ICL description to identify them; the signals are automatically recognized as existing DFT signals. Refer to the `tessent_dft_signal_*` attributes in “[icl_port](#)” on page 3592 for a description of the ICL Port Attributes that you must use to identify DFT signals on your IJTAG node. “[Example 2](#)” on page 226 shows an example of such an ICL module.

DFT Signal Creation

The DFT signals are created when running the [process_dft_specification](#) command. You use [create_dft_specification](#) to create the `DftSpecification`.

Creating DFT Signals With `-create_with_tdr`

When creating static DFT signals with `-create_with_tdr`, the `IjtagNetwork` wrapper is present and contains a `Tdr(sri_ctrl)` wrapper with the `tessent_dft_function` attribute set to “`scan_resource_instrument_dft_control`”. Do not add or delete this wrapper. The wrapper’s content is auto adjusted by the tool to match the list of static DFT controls you specified.

Note

 The `create_dft_specification` command adds the `Tdr(sri_ctrl)` wrapper under a `SIB` wrapper `Sib(sri_ctrl)` so the tool does not need to scan the TDR every time a lower block is accessed.

The `add_dft_signals` command can only be called after you have run the `set_design_level` command, unless the design level is already imported by the `read_design` command. The `design_level` affects the default behavior of the command as described in the note below:

Note

 When the `design_level` is set to `sub_block` using the `set_design_level` command, the static DFT signals default to be created as input ports by the name of the DFT signal. Sub blocks are by definition processed independently at the RTL level but synthesized as part of their parent physical block. The DFT signals created at the boundary of the sub-block are connected to the DFT signal by the same name added in the parent physical block. Typically, you do not add the `int_ltest_en` and `ext_ltest_en` DFT signals inside a sub-block, as only physical blocks can be wrapped cores. If for some reason you need to add the `int_ltest_en` or `ext_ltest_en` in a sub-block, by default, they are created as ports on the sub-block and connected to the respective DFT signal at the parent level. This means that you are not able to assert `int_ltest_en` on in the parent and off inside the child `sub_block`. If you need to do that, use the `-create_with_tdr` switch to provide an independent source inside the sub-block module.

If you are only adding dynamic DFT signals, then you must run the `process_dft_specification` command even if the `DftSpecification` contains no `IjtagNetwork` wrapper. The tool creates the missing ports and exports the DFT signals into the `.tcd` file located in the `dft_inserted_designs` directory such that the signals are automatically imported in a subsequent Tessent Shell invocation for the future DFT insertion passes and for ATPG setup.

The DFT signals you add in one insertion pass are automatically imported in the subsequent DFT insertion passes. If the location of the DFT signal is no longer present, the tool issues a warning telling you that the DFT signal could not be imported. For example, if you added `edt_clock` with `-create_from_other_signals` in `pass1`, a clock gater is added to create the DFT signal. If you synthesized the RTL and forgot to preserve the cells with the special `persistent_cell_prefix` value, the clock gater may have changed names, and it is no longer possible to find the signal.

Table 3-10. Pre-Registered Static Global DFT Control Signal Names

Static DFT Signal Name	Usage and Default Implementation - Global DFT Control
all_test	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 1</p> <p>value_in_pre_scan_drc: 1</p> <p>A global DFT control signal that is set high during all tests including all logic test and non-logic test modes such as MemoryBIST.</p> <p>This signal is used by default when using the add_dft_control_points command and the <code>-dft_signal_source_name</code> switch is not specified. The signal is also used to control the select of the multiplexers inserted when the <code>add_dft_control_points</code> command refers to a pin that already has a functional source.</p> <p>Refer to Table 3-9 on page 177 in the add_dft_control_points command description for more details.</p> <p>The <code>all_test</code> signal is special in that the signal is automatically activated during all test modes. The create_patterns_specification command automatically sets it to on in all blocks where it exists. The set_static_dft_signal_values command automatically infers it high whenever another DFT signal is set in a given block.</p> <p>Because the <code>all_test</code> signal is used to force open clock gaters in the fan-in of the reference of generated clocks, it is forced high during ICL extraction such that clocks can be traced through those clock gaters. The ICL ends up not describing the presence of the clock gater along the clock path, but because it is opened by <code>all_test</code>, it can be assumed that the <code>all_test</code> signal is guaranteed to be active during all test modes because of the automation mentioned previously. If you want to control a clock gater with a different DFT signal that you want to control manually, the tool cannot force it high during ICL extraction as the ICL model becomes invalid when the signal is not asserted high. If you want to use a different DFT signal anyway, the clock gater must be modeled in the ICL file. Example 3 of the extract_icl reference page describes how to do that.</p>

Table 3-10. Pre-Registered Static Global DFT Control Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Global DFT Control
<p>bscan_clamp_enable</p>	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A global DFT control signal that is used to force the Boundary Scan wire called select_jtag_output to one. This enables pre-loading the boundary scan with a set of values and forcing those values on the output during any test. The connection between the Boundary Scan interface module and this signal is automatic as soon as the DFT signal is added.</p>
<p>dft_signal_disable</p>	<p>Usage: Global DFT Control</p> <p>reset_value : 1</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 0</p> <p>A global DFT control signal that is set low during all tests, including all logic test and non-logic test modes such as MemoryBIST.</p> <p>This signal provides functional-mode fault tolerance in the TDR register hosting static DFT signals. The tool creates it in the Tessent IP when you request that static DFT signals interacting with functional logic be turned off during the functional mode of design operation. Make this request with the set_dft_signals_options or add_dft_signals commands.</p> <p>The tool adds the dft_signal_disable signal automatically when you implement the functional safety solutions as described in the Tessent Shell User's Manual. Refer to "set_dft_signals_options" on page 2320 for further information.</p>
<p>occ_kill_clock_en</p>	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 0</p> <p>A DFT signal used to drive the kill_clock_en port on the OCC module. Refer to the kill_clock_mode property description in the OCC wrapper.</p>

Table 3-10. Pre-Registered Static Global DFT Control Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Global DFT Control
output_pad_disable	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A global DFT control signal that is used to force the output pad buffers in high-z using the force_disable wire of the Boundary Scan. This enables forcing the output pads in high-z during any test and save on power. The connection between the Boundary Scan interface module and this signal is automatic as soon as the DFT signal is added.</p> <p> Note: If you add this signal at the top level and you have inserted BoundaryScan with the max_segment_length_for_logicest property not equal to off, the output_pad_disable DFT signal is automatically connected to the boundary scan interface module and force to_force_disable high when asserted. Then, use the set_static_dft_signal_values output_pad_disable 1 command to tri-state the output pad buffers during logicest modes.</p>
ssn_en	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A global DFT control signal that is used to activate the SSN data path. The typical usage of this DFT signal is to activate the Auxiliary data path when the SSN data paths share functional ports at the top level. You can use this DFT signal to sensitize any logic you may have along the SSN data path such as power isolation cells. This DFT signal is automatically asserted high during ICL extraction and the DFT signal is automatically written to 1 when ever the SSN network is used. You don't need to add this signal explicitly. It will be inferred with -create_from_tdr during process_dft_specification if it is needed.</p>

Table 3-10. Pre-Registered Static Global DFT Control Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Global DFT Control
tck_occ_en	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 0</p> <p>A global DFT control signal that is used to enable the mini-OCC present inside the Sib(sti) node. The signal is automatically set to 1 when you invoke the add_core_instances command on the Sib(sti) instances.</p>
tck_select	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 0</p> <p>A global DFT control signal that is used to control the multiplexer used to inject TCK at the base of the clock trees. This signal is not needed when using the Tessent OCC as it is already equipped with a TCK multiplexer controlled by a local TDR bit.</p>
tristate_enable_nc_test	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 0</p> <p>A global DFT control signal that switches the Boundary Scan interface module to support the use of the update and force disable control signals in support of the <code>tristate_enable_non_contacted</code> test (refer to “RunTest” on page 4275).</p> <p>This input is available if the <code>tristate_non_contacted_test_support</code> property in the BoundaryScan wrapper is set to “on.”</p>
tristate_enable_nc_test_type	<p>Usage: Global DFT Control</p> <p>reset_value : 0</p> <p>local : 0</p> <p>global: 1</p> <p>A global DFT control signal that switches the behavior selected by <code>tristate_enable_nc_test</code> between the two <code>NonContactedPinOptions/TristateEnableOptions/test_path</code> values (local and global).</p> <p>This input is available if the <code>tristate_non_contacted_test_support</code> property in the BoundaryScan wrapper is set to “on.”</p>

Table 3-11. Pre-Registered Static Logic Test Control Signal Names

Static DFT Signal Name	Usage and Default Implementation - Logic Test Control
async_set_reset_static_disable	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 0</p> <p>A logic test control signal that is used to completely turn off all asynchronous set and reset signals during logic test modes. This signal is combined with scan_en to create the dynamic DFT signal called async_set_reset_dynamic_signal as described in Table 3-13 on page 215.</p> <p>Normally, the asynchronous set and reset signals are only turned off when scan_en is high. The state of the functional circuit determines if the reset and set pins are active or not during capture cycles.</p> <p>Setting the async_set_reset_static_disable signal to high keeps the set and reset pins gated off even during the capture cycle. It is normally set low but can be set high using the set_static_dft_signal_values command.</p>
capture_per_cycle_static_enable	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A logic test control signal that enables observation scan observe points in the hybrid TK/LBIST flow. Observation scan uses observe test points that are monitored during every shift cycle as opposed to traditional observe points that are monitored only in capture. The capture_per_cycle_static_enable signal controls these test points.</p>
control_test_point_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A logic test control signal that is used to enable the control test point.</p>

Table 3-11. Pre-Registered Static Logic Test Control Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Logic Test Control
ltest_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 1</p> <p>A logic test control signal that is used to enable the logic test mode. This signal is force high during all logic test modes.</p>
mcp_bounding_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A logic test control signal that is used to enable the X-bounding of false paths and multicycle paths.</p>
memory_bypass_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 1</p> <p>A logic test control signal that is used to enable the isolation around the memories. This signal is set to 1 by default during logic test but can be set low using the set_static_dft_signal_values command.</p>
observe_test_point_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A logic test control signal that is used to enable the observation test points.</p>
se_pipeline_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: 0</p> <p>A logic test control signal that is used to enable the pipelining of the scan enable signal in order to perform launch off shift at-speed test.</p>

Table 3-11. Pre-Registered Static Logic Test Control Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Logic Test Control
wrapper_toggle_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test : 0</p> <p>value_in_pre_scan_drc: X</p> <p>A logic test control signal that is used to toggle the type of feedback (direct or inverting) in holding wrapper cells created with the “programmable_hold” capture window behavior. This DFT signal is OR-ed by default with a holding scan cell, giving ATPG the ability to request that wrapper cells hold or toggle.</p>
x_bounding_en	<p>Usage: Logic Test Control</p> <p>reset_value : 0</p> <p>default_value_in_all_test :0</p> <p>value_in_pre_scan_drc: X</p> <p>A logic test control signal that is used to enable the X-bounding circuitry caused by X sources.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
controller_chain_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: unwrapped</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the controller chain mode scan configuration.</p> <p>You can use this scan mode to control the controller chain mode when not using wrapper chains because the scan_mode_type of this signal is unwrapped.</p> <p>Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p> <p>Refer to “Controller Chain Mode” in the <i>Hybrid TK/LBIST Flow User’s Manual</i> for details.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
edt_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: unwrapped</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the EDT scan configuration.</p> <p>You can use this scan mode to control the edt mode when not using wrapper chains because the scan_mode_type of this signal is unwrapped.</p> <p>When using wrapper chains, you use int_edt_mode or int_mode instead. Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
<p>ext_edt_mode</p>	<p>Usage: Scan Mode reset_value : 0 scan_mode_type: external value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the external EDT scan mode when using wrapper chains. This DFT signal has scan_mode_type equal to external and is used to configure the external EDT scan configuration of a wrapped core. Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values.</p> <p>Typically, the wrapper chains are not driven by an EDT controller but it is an option that can be used. If you are using the multi- and single chain bypass mode built in the EDT controller, you do not need this DFT signal. Instead you use the ext_mode DFT signal. You only use this signal if you have an EDT to drive your wrapper chain and you are implementing the external single and multi-chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>
<p>ext_mode</p>	<p>Usage: Scan Mode reset_value : 0 scan_mode_type: external value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the external scan mode when using wrapper chains. This DFT signal has scan_mode_type equal to external and is used to configure the external scan configuration of a wrapped core. Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
<p>ext_multi_mode</p>	<p>Usage: Scan Mode reset_value : 0 scan_mode_type: external value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the external multi-chain scan mode when using wrapper chains. Typically, the wrapper chain are not driven by an EDT controller, but it is an option that can be used. If you are using the multi- and single chain bypass mode built in the EDT controller, you do not need this DFT signal. Instead you use the ext_mode DFT signal. You only use this signal if you have an EDT controller to drive your wrapper chain and you are implementing the external single and multi-chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>
<p>ext_single_mode</p>	<p>Usage: Scan Mode reset_value : 0 scan_mode_type: external value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the external single chain scan mode when using wrapper chains. Typically, the wrapper chain are not driven by an EDT controller, but it is an option you can use. If you are using the multi- and single chain bypass mode built in the EDT controller, you do not need this DFT signal. Instead you use the ext_mode DFT signal. You only use this signal if you have an EDT to drive your wrapper chains, and you are implementing the single and multi-chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
int_edt_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: internal</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the EDT scan mode when using wrapper chains because the scan_mode_type of this signal is internal. Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values. If you are using the multi- and single chain bypass mode built in the EDT controller, you do not need this DFT signal. Instead you use the int_mode DFT signal. You only use this signal if you are implementing the single and multi-chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>
int_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: internal</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the internal mode when using wrapper chains and you are using the multi and single chain bypass mode built in the EDT controller. This DFT signal has scan_mode_type equal to internal and is used to configure the internal scan configuration of a wrapped core.</p> <p>Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values. If you are implementing the single and multi chain bypass mode at the scan insertion stage, use the int_edt_mode, int_multi_mode, and int_single_mode signals.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
int_multi_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: internal</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the internal multi-chain scan mode when using wrapper chains. If you are using the multi- and single chain bypass mode built in the EDT controller, you do not need this DFT signal. Instead you use the int_mode DFT signal.</p> <p>This DFT signal has scan_mode_type equal to internal and is thus to be used to configure the internal multi-chain scan configuration of a wrapped core. Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values. You only use this signal if you are implementing the single and multi-chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
int_single_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: internal</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the internal single chain scan mode when using wrapper chains. This DFT signal has scan_mode_type equal to internal and is used to configure the internal single chain scan configuration of a wrapped core. Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values. If you are using the multi- and single chain bypass mode built in the EDT controller, you do not need this DFT signal. Instead you use the int_mode DFT signal. You only use this signal if you are implementing the single and multi-chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>
multi_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: unwrapped</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the multi-chain bypass scan configuration. You use this scan mode when not using wrapper chains because the scan_mode_type of this signal is unwrapped.</p> <p>When using wrapper chains, you use int_multi_mode instead. Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values. If you are using the bypass mode built in the EDT controller, you do not need this DFT signal. You only use this signal if you are implementing the multi-chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
<p>promoted_cells_mode</p>	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: unwrapped</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the promoted cells scan mode. You use this mode when you have OCCs driven by embedded PLLs inside a wrapped core and this core is instantiated below another wrapped core. In that case, you simply add this DFT signal in the lower level wrapped core during OCC insertion and use “add_scan_mode promoted_cells_mode” during scan insertion.</p> <p>Chains belonging to OCCs driven by embedded PLLs are automatically included in this mode. They are also automatically included in all scan modes of type external. At the next level up, when doing scan insertion in the parent core, the chain associated with the promoted_cells_mode in the child cores is automatically promoted to belong to the wrapper chains of the parent core so that the OCC is accessible from the top level using the wrapper chains of its child wrapped cores.</p>
<p>retargeting#_mode = 1, 2, ...,8</p>	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: external</p> <p>value_in_pre_scan_drc: X</p> <p>A set of scan mode signals used to configure the retargeting modes that make use of the internal scan modes of child blocks. For example: retargeting1_mode can be used to provide scan channel data to the internal scan mode of core_a, core_b, and core_c, and retargeting2_mode can be used to provide scan channel data to the internal scan mode of core_d, and core_e.</p> <p>If you have more than 8 retargeting combinations at a given level, you simply need to register more scan mode signals of type retargeting using the register_static_dft_signal_names command.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-12. Pre-Registered Static Scan Mode Signal Names (cont.)

Static DFT Signal Name	Usage and Default Implementation - Scan Mode
single_mode	<p>Usage: Scan Mode</p> <p>reset_value : 0</p> <p>scan_mode_type: unwrapped</p> <p>value_in_pre_scan_drc: X</p> <p>A scan mode signal that is used to enable the single chain bypass scan mode. You can use this scan mode when not using wrapper chains because the scan_mode_type of this signal is unwrapped.</p> <p>Refer to the description of the set_static_dft_signal_values command to understand the importance of using scan mode DFT signals with the accurate scan_mode_type values. If you are using the single chain bypass mode built in the EDT controller, you do not need this DFT signal. You only use this signal if you are implementing the single chain bypass mode at the scan insertion stage.</p> <p>In dft -scan context, this signal is automatically associated with the added scan mode when the name of the scan mode matches the name of the DFT signal. When you name the scan mode differently from the DFT signal name, use the -enable_dft_signal <dft_signal_name> switch to associate them together.</p>

Table 3-13. Pre-Registered Dynamic DFT Signal Names

Dynamic DFT Signal Name	Usage and Default Implementation
<p>async_set_reset_dynamic_disable</p>	<p>A DFT signal that is used to turn off the asynchronous set and reset pins of scannable flip-flops during shift mode. This signal is high during the load_unload cycles and is permitted to return to low in the capture cycles. When using the <code>-create_from_other_signals</code> switch, it is created by ORing the <code>scan_en</code> and the <code>async_set_reset_static_disable</code> DFT signals. The DFT signals <code>scan_en</code> and <code>async_set_reset_static_disable</code> must be added before the <code>async_set_reset_dynamic_disable</code> DFT signal can be added using the <code>-create_from_other_signals</code> switch.</p> <p>If you want to create this DFT signal without creating the <code>async_set_reset_static_disable</code> DFT signal, use the <code>-source_node</code> switch and map the <code>async_set_reset_dynamic_disable</code> DFT signal on the same node you have defined the <code>scan_en</code> DFT signal.</p> <p>By default, the <code>async_set_reset_static_disable</code> signal is set to 0 such that the <code>async_set_reset_dynamic_disable</code> signal follows <code>scan_en</code>. However, the set and reset pins can be turned off systematically by setting the <code>async_set_reset_static_disable</code> signal to 1 using the set_static_dft_signal_values command. You can choose to set the <code>async_set_reset_static_disable</code> signal to avoid D1 violations or to reduce the amount of care bits needed by ATPG to turn off the set and reset signals to observe the fan-in of the scannable flip-flops. You must, however, generate some patterns with the <code>async_set_reset_static_disable</code> signal set to 0 to gain coverage of the reset circuitry.</p> 

Table 3-13. Pre-Registered Dynamic DFT Signal Names (cont.)

Dynamic DFT Signal Name	Usage and Default Implementation
<p>edt_clock</p>	<p>A DFT signal that is used to supply a clock to the EDT controller. This can be an independent primary input, but it can also be synthesized using a clock gater driven by test_clock and having its enable sourced by scan_en. This is the recommended method as it permits sharing a common clock source for both the edt_clock and the shift_capture_clock. The DFT signal scan_en and test_clock must be added before the edt_clock can be added with the -create_from_other_signals switch. Refer to Figure 3-10 on page 219 for an illustration of its waveforms.</p> <div data-bbox="649 640 1242 766" data-label="Diagram"> <pre> graph LR scan_en --> AND[AND] test_clock --> AND AND --> edt_clock </pre> </div> <p>When hybrid LogicBIST is present, this gater is created within the LogicBIST controller. If this gater was inserted in a previous insertion pass, then it is removed when inserting the hybrid controller and the existing connections are moved to the LogicBIST output port.</p> <p>If you are using SSN with a ScanHost node, the edt_clock DFT signal can be inferred on the edt_clock output port of the ScanHost node. If you do not specify this signal and you set “edt_clock_present off” on the ScanHost, the signal is not created even if it is needed by EDT, OCC, or similar functionality. If you do explicitly add this signal, it will be redefined during the execution of the process_dft_specification command.</p>
<p>edt_update</p>	<p>A DFT signal that is used to supply the update enable port of the EDT controller. This signal is also used to create the shift_capture_clock. Refer to Figure 3-10 on page 219 for an illustration of its waveforms.</p> <p>If you are using SSN with a ScanHost node, the edt_update DFT signal can be inferred on the edt_update output port of the ScanHost node. You do not need to add it explicitly. If you do, the tool will redefine it during the execution of the process_dft_specification command.</p>
<p>input_wrapper_scan_en</p>	<p>A DFT signal that is used (only for third-party scan insertion) to supply the scan_en signal to the input wrapper chains. When using the -create_from_other_signals switch, it is created by ORing scan_en with int_ltest_en.</p> <div data-bbox="722 1753 1323 1816" data-label="Diagram"> <pre> graph LR scan_en --> OR[OR] int_ltest_en --> OR OR --> input_wrapper_scan_en </pre> </div>

Table 3-13. Pre-Registered Dynamic DFT Signal Names (cont.)

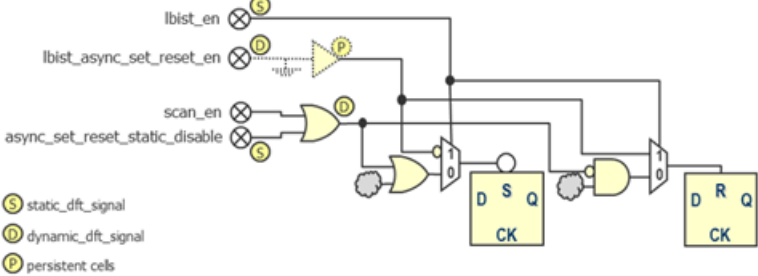

Dynamic DFT Signal Name	Usage and Default Implementation
<p>lbist_async_set_reset_dynamic_enable</p>	<p>A DFT signal that is used to enable the asynchronous set and reset pins of scannable flip-flops during the LogicBIST capture procedure. This signal is low during the LogicBIST shift cycles. This signal is multiplexed with the dynamic DFT signal <code>async_set_reset_dynamic_disable</code> and uses the static DFT signal <code>lbist_en</code> as the mux select.</p>  <p>If the Hybrid LogicBIST controller is not inserted at the same time as the DFT signal, then the tool uses a tied-off persistent buffer to anchor the DFT signal. When the tool inserts the LogicBIST controller, it deletes the buffer and moves the buffer fanout to a LogicBIST controller output port.</p>
<p>output_wrapper_scan_en</p>	<p>A DFT signal that is used (only for third-party scan insertion) to supply the <code>scan_en</code> signal to the output wrapper chains. When using the <code>-create_from_other_signals</code> switch, it is created by ORing <code>scan_en</code> with <code>ext_ltest_en</code>.</p> 
<p>scan_en</p>	<p>A DFT signal that is used to define the source of <code>scan_en</code>. When using an OCC, this signal is constrained off during the capture cycle. When the <code>async_set_reset_static_disable</code> signal is not set to 1, you must make sure the <code>scan_en</code> source is high during all cycles of the load_unload procedure to avoid D1 violations. Refer to Figure 3-10 on page 219 for an illustration of its waveforms.</p> <p>If you are using SSN with a ScanHost node, the <code>scan_en</code> DFT signal can be inferred on the <code>scan_en</code> output port of the ScanHost node. You do not need to add it explicitly. If you do, the tool will redefine it during the execution of the <code>process_dft_specification</code> command.</p>

Table 3-13. Pre-Registered Dynamic DFT Signal Names (cont.)

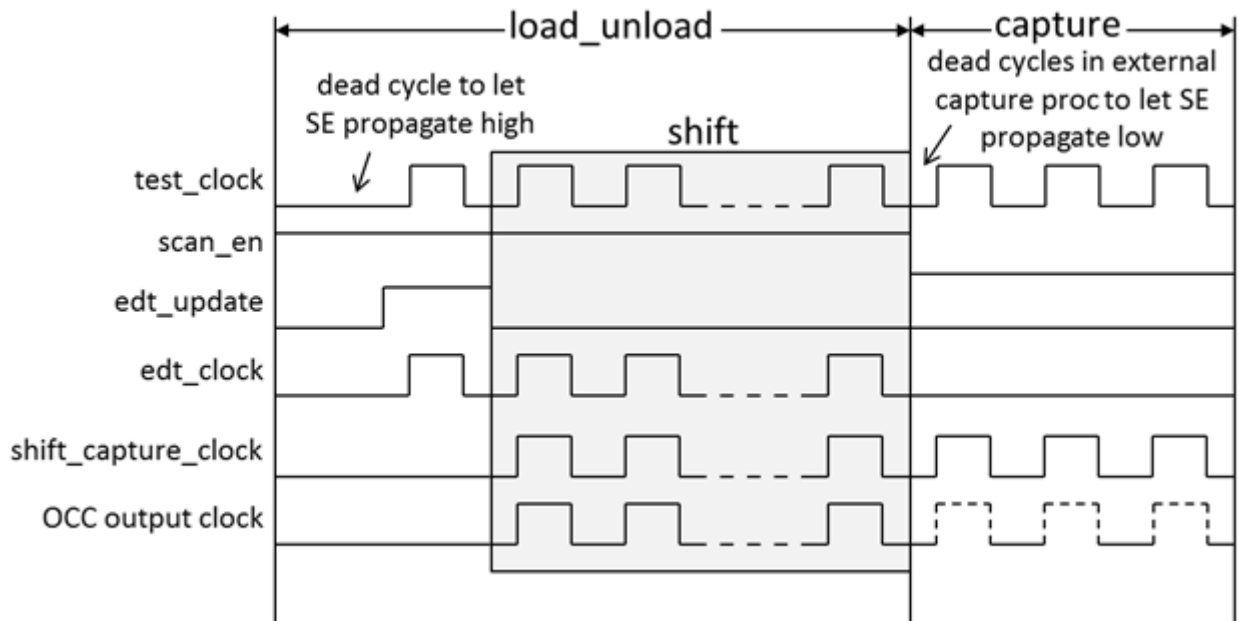

Dynamic DFT Signal Name	Usage and Default Implementation
<p>shift_capture_clock</p>	<p>A DFT signal that is used to supply the slow clock to the OCC controller. This can be an independent primary input, but it can also be synthesized using a clock gater driven by test_clock and having its enables sourced by edt_update. This is the recommended method as it permits sharing a common clock source for both the edt_clock and the shift_capture_clock. The DFT signal edt_update and test_clock must be added before the shift_capture_clock can be added with the -create_from_other_signal switch. Refer to Figure 3-10 on page 219 for an illustration of its waveforms.</p>  <pre> graph LR edt_update --> B1[] B1 --> N1[] N1 --> A1[] test_clock --> A1 A1 --> shift_capture_clock </pre> <p>When hybrid LogicBIST is present, this gater is created within the LogicBIST controller. If this gater was inserted in a previous insertion pass, it is removed when inserting the hybrid controller and the existing connections are moved to the LogicBIST output port.</p> <p>If you are using SSN with a ScanHost node, the shift_capture_clock DFT signal can be inferred on the shift_capture_clock output port of the ScanHost node. If you do not specify this signal and you set “shift_capture_clock_present off” on the ScanHost, the signal is not created even if it is needed by EDT, OCC, or similar functionality. If you do explicitly add this signal, it will be redefined during the execution of the process_dft_specification command.</p>

Table 3-13. Pre-Registered Dynamic DFT Signal Names (cont.)

Dynamic DFT Signal Name	Usage and Default Implementation
test_clock	<p>A DFT signal that defines a clock input as the test_clock, which is to be used as the common source to synthesize the edt_clock and the shift_capture_clock. You do not need this signal if the edt_clock and the shift_capture_clock are sourced by independent sources. Refer to Figure 3-10 on page 219 for an illustration of its waveforms.</p> <p>Note: You cannot share or reuse the test_clock with an already-existing functional clock that feeds sequential elements intended to be tested with ATPG. The test_clock needs to be a separate independent clock because the test_clock must pulse an extra amount of time to initialize the EDT without disturbing the functional clock domains.</p> <p>If scan_signals_bypass on the ScanHost is off, test_clock is created if you specify a test_clock. If scan_signals_bypass is on and you specify test_clock, it is created on the ScanHost node only if the control points require it. If you specify “test_clock_present off” on the ScanHost, the test_clock is not created even if it is required.</p> <p>test_clock connections are not moved automatically to the ScanHost sourcing test_clock signal. Do this manually with the following command:</p> <pre>add_dft_control_points pin_port_net_spec -type \ dynamic_dft_control -dft_signal_source_name test_clock -ignore_existing_sources</pre>

Figure 3-10. Waveforms of Selected Dynamic DFT Signals

Knowing Which Signals to Add for Logic Test

Follow these instructions to know which signals to add for logic test:

- When you have memory BIST:

```
add_dft_signals memory_bypass_en
```

- When you have at least one Scan Tested Instrument like memory BIST or boundary scan (when boundary scan segments are used for logic test):

```
add_dft_signals tck_occ_en
```

- When you are using logic test:

```
add_dft_signals ltest_en async_set_reset_static_disable
```

- When you are using logic test without SSN:

```
add_dft_signal scan_en -source_nodes my_scan_en
```

- When you are creating a wrapped core:

```
add_dft_signals int_ltest_en ext_ltest_en  
add_dft_signals int_mode ext_mode
```

- When using EDT without SSN, create the `shift_capture_clock` and `edt_clock` from a common test_clock:

```
add_dft_signals test_clock edt_update -source_nodes \  
{my_test_clock my_edt_update}  
add_dft_signals shift_capture_clock edt_clock \  
-create_from_other_signals
```

- When not using EDT nor SSN:

```
add_dft_signals shift_capture_clock -source_nodes my_test_clock
```

- When reusing boundary scan for logic test at the top level, and you want to be able to perform logic test without contacting inputs that have boundary scan cells:

```
add_dft_signals int_ltest_en output_pad_disable
```

Arguments

- *name* ...

A required repeatable string value used to specify one of more names of DFT signals to add. You can specify several names in one command line invocation. You can also supply several names in a single well formatted Tcl list. The name values must corresponds to built in DFT signal names or user registered ones. Refer to the [register_static_dft_signal_names](#) command description for instructions on how to register your own.

- `-source_nodes pin_port_spec`

An optional switch that is used to associate ports or pins to the DFT signal. This option is mandatory when adding the following dynamic DFT signals: `scan_en`, `test_clock`, and `edt_update`. Specified pin names must refer to existing objects. Port names are permitted to refer to ports that are to be created as long as they are scalar names and the design level set using the `set_design_level` command is not “chip”. When the design level is set to “chip”, specified port names must refer to existing ports and the ports must be connected to a properly described pad buffer cell. The connection to the DFT signal automatically maps the specified top-level port to the output pin of its associated input pad buffer.

If you have added auxiliary input logic on the input pad used to source the dynamic DFT signals such as `scan_en`, `test_clock` and `edt_clock`, the DFT signal is automatically mapped on the auxiliary input data pin and an “`add_dft_control_point -dft_signal_source_name ltest_en`” command is inferred to control the auxiliary input enable pin as shown in Example 5. Refer to the documentation of the `get_auxiliary_pins` and the `add_dft_modal_connections` commands for a detailed description of the auxiliary logic and how to describe third party implementation using a Tcl dictionary called “`::auxiliary_data_dict`”.

If you do not specify any of the following switches:

- `-create_from_other_signals`
- `-create_with_tdr`
- `-source_node`

the `-create_with_tdr` switch is assumed when the `design_level` is not a `sub_block`; otherwise the `-source_node` switch with a port name equal to the DFT signal name is inferred by the tool. This is the recommended implementation for all static DFT signals. Refer to the `set_static_dft_signal_values` command to find how the setting of the static DFT signals is automated when sourced by IJTAG.

- `-make_ijtag_port`

An optional switch that can be used when adding a static DFT signal with the `-source_nodes` switch referring to ports. The ports are identified as `DataInPorts` when running `extract_icl`. When running ICL extract at the next level, those ports are verified to be properly sourced by IJTAG data ports. The `set_static_dft_signal_values` command remains usable for setting those static DFT signals specified on a port when you also specify the `-make_ijtag_port` switch. The switch is inferred automatically when the static DFT signal is defined on a port and the `design_level` was specified as “chip” using the `set_design_level` command. It is also inferred when the `-source_node` switch is inferred to be equal to the DFT signal name when the `design_level` was specified as “sub_block” using the `set_design_level` command. Refer to Example 4.

- `-create_from_other_signals`

An optional switch that specifies to create the DFT signal from other signals. The list of the DFT signals that can be created from other signals are `edt_clock`, `shift_capture_clock`, `async_set_reset_dynamic_disable`, `input_wrapper_scan_en`, and

output_wrapper_scan_enable. It is actually recommended that you use the -create_from_other_signals switch when adding them as it make the timing closure easier during synthesis and layout.

Refer to [Table 3-13](#) on page 215 for a description of those signals and how they are synthesized from other signals. [Figure 3-10](#) on page 219 shows their respective waveforms.

- -parent_instance *parent_instance*

An optional switch-value pair that specifies an instance in which to instantiate the clock gating cell used to synthesize the edt_clock and the shift_capture_clock signals. When left unspecified, the parent instance defaults to the current design. You can create several copies of the clock gating cells as long as you specify a different parent instance for each one of them. The other three dynamic signals that can be created from other signals only have one copy. The OR gate is instantiated in the parent instance of the static DFT signal that feeds one input of the OR gate.

- -leaf_instance_name *leaf_instance_name*

An optional switch-value pair that specifies the leaf name of the logic gate used to synthesize the logic signal. By default, the leaf instance name is the name of the DFT signal prefixed by the value specified with the persistent_cell_prefix property inside the [DftSpecification](#) wrapper. The default is “tessent_persistent_cell”.

- -create_with_tdr

An optional switch that specifies that the DFT signal is to be created from a TDR. This switch is assumed when the -source_node and the -create_from_other_signals switches are not specified. This switch is only permitted when adding static DFT signals.

This switch is assumed when the -source_node and the -create_from_other_signals switches are not specified or inferred. Refer to the -source_node switch description to know when it is inferred automatically.

- -disable_for_functional_safety {on | off | auto}

An optional switch that specifies that a signal created from a TDR is created with redundancy gating. This switch is only valid when the -create_with_tdr switch is specified or inferred.

on — Gating logic is added.

off — Gating logic is not added.

auto — This is the option default. The tool uses the value set with the [set_dft_signals_options](#) command.

- -add_hold_scan_cell {on | off | auto}

An optional switch and literal pair to indicate whether a DFT signal should be created with or without additional control logic for ATPG.

Note

 The insertion of the holding scan cell requires that the `shift_capture_clock` and `ltest_en` DFT signals are already defined. If they do not exist, they will be automatically created.

If the tool automatically creates the `shift_capture_clock` signal, the `edt_update` and `test_clock` signals are also created because they are required for the `shift_capture_clock` clock gater. The tool reports the following notes when automatically creating these signals:

Note: Adding Dft signal 'edt_update' with option '-source_nodes edt_update' because it is needed for holding scan cell

Note: Adding Dft signal 'test_clock' with option '-source_nodes test_clock' because it is needed for holding scan cell

Note: Adding Dft signal 'shift_capture_clock' with option '-create_from_other_signals' because it is needed for holding scan cell

Note: Adding Dft signal 'ltest_en' because it is needed for holding scan cell

Restriction

 Automatic creation of the `shift_capture_clock` signal is not supported at the chip level.

The DFT signals that support this option are:

- o `async_set_reset_dynamic_disable` (dynamic)
- o `x_bounding_en` (static)
- o `mcp_bounding_en` (static)
- o `control_test_point_en` (static)
- o `observe_test_point_en` (static)
- o `wrapper_toggle_en`

on — The supported DFT signal is created with additional control logic for ATPG.

off — The supported DFT signal is created without additional control logic for ATPG.

auto — This is the option default. The [StaticDftSignals](#) and [DynamicDftSignals](#) wrapper data for this option is inherited if modified before using this switch. By default, unless modified before using this switch, the DefaultsSpecification configuration syntax for inserting a holding scan cell for ATPG control defaults to “on” for the `wrapper_toggle_en` signal and “off” for all other valid DFT signals.

- `-hold_scan_cell_disable dft_signal`

An optional switch and value pair that specifies the DFT signal used to turn off the holding scan cell.

add_dft_signals

dft_signal should be a pre-registered DFT signal. If the signal does not exist, the tool automatically adds it.

Examples**Example 1**

The following example defines the DFT signals needed for each test block in the `my_core1` design. The design is implementing memory BIST and logic tests using EDT and OCC. The first dofile adds DFT signals while inserting memory BIST and IJTAG into the RTL during RTL Pass1. The second dofile adds and automatically connects the `Sib(sti)` and DFT signals in the second pass, as it inserts the EDT and OCC controllers during RTL Pass2. Finally, the third dofile uses the DFT signals `int_mode` and `ext_mode` from RTL Pass1 during the Scan Insertion Pass with the `add_scan_modes` command.

RTL Pass1

```

set_context dft -rtl

```

Example 2

This example shows the DFT signals pre-existing on a third-party TDR. The first part shows the DataOutPort attributed in the ICL module. The [tessent_dft_function](#) attribute identifies the ICL module as having attributed DFT signals and is mandatory for the attributed DFT signals to be recognized. For the `tessent_dft_signal_*` attributes, refer to the [icl_port](#) data model section. The second part calls the [report_dft_signals](#) command once the design has been elaborated and the ICL module matched to its Verilog counterpart to show how the DFT signals were auto detected and added as existing signals.

Example 3

This example shows you which DFT signal you need to add and when:

```
# When you have memory BIST  
add_dft_signals memory_bypass_en  
  
# When you have at least one Scan Tested Instrument like Memory BIST  
add_dft_signals tck_occ_en  
  
# When you are using logictest  
add_dft_signals ltest_en  
add_dft_signals scan_en -source_node my_scan_en  
  
# When you are building a wrapped core  
add_dft_signals int_ltest_en ext_ltest_en int_mode ext_mode  
  
# When using EDT  
  
add_dft_signals test_clock edt_update \  
  -source_node {my_test_clock my_edt_update}  
add_dft_signals edt_clock shift_capture_clock \  
  -create_from_other_signals  
  
# When not using EDT  
add_dft_signals shift_capture_clock -source_node {my_test_clock}  
report_dft_signals
```

```
// Existing and to be created DFT signals
// =====
// -----
// Name          Status      Origin   Type          Location
// -----
// edt_clock     To be      User    ClockGateAnd
//               created    added
//               <persistent_cell_prefix>
//               edt_clock
// edt_update    To be      User    Port          my_edt_update
//               created    added
// ext_ltest_en  To be      User    IJTAG         register
//               created    added
// ext_mode      To be      User    IJTAG         register
//               created    added
// int_ltest_en  To be      User    IJTAG         register
//               created    added
// int_mode      To be      User    IJTAG         register
//               created    added
// ltest_en      To be      User    IJTAG         register
//               created    added
// memory_bypass_en To be      User    IJTAG         register
//               created    added
// scan_en       To be      User    Port          my_scan_en
//               created    added
// shift_capture_clock To be      User    ClockGateAnd
//               created    added
//               <persistent_cell_prefix>
//               shift_capture_clock
// tck_occ_en    To be      User    IJTAG         register
//               created    added
// test_clock    To be      User    Port          my_test_clock
//               created    added
//
```

Example 4

The following example illustrates how the `-make_ijtag_port` switch is automatically inferred for the static DFT signals defined on ports when the `design_level` is chip. In this example, the node `gpio[136]` (in red) is the inferred `ijtag_port`.

```
add_dft_signals test_clock edt_update ltest_en \
-source_node {gpio[135] gpio[134] gpio[136]}
report_dft_signals
```

```
// Existing and to be created DFT signals
// =====
// -----
// Name          Status      Origin   Type          Location
// -----
// edt_update    Existing   User    added         Port          gpio[134] -> gpio134/C
// ltest_en      Existing   User    added         IJTAG port    gpio[136] -> gpio136/C
// test_clock    Existing   User    added         Port          gpio[135] -> gpio135/C
```

Example 5

The following example uses `add_dft_signal` to declare the source of `scan_en`, `test_clock` and `edt_update` DFT signals. The pads are equipped with auxiliary data logic using the [AuxiliaryInputOutputPorts](#) wrapper during boundary scan insertion, so they are automatically mapped to the auxiliary input pin and the auxiliary input enable pins are inferred to be driven by the “`ltest_en`” DFT signal.

```
add_dft_signals scan_en test_clock edt_update -source_node {gpio[32:30]}
```

```
// Note: Adding DFT signal 'ltest_en' with the -create_with_tdr option.  
  
// Note: Inferred 'add_dft_control_points  
// top_rtl1_tessent_bscan_logical_group_DEF_inst/gpio_32_AuxInEn  
// -dft_signal_source_name ltest_en' because the DFT signal 'scan_en' is  
// sourced by an auxiliary data input pin.  
  
// Note: Inferred 'add_dft_control_points  
// top_rtl1_tessent_bscan_logical_group_DEF_inst/gpio_31_AuxInEn  
// -dft_signal_source_name ltest_en' because the DFT signal 'test_clock'  
// is sourced by an auxiliary data input pin.  
  
// Note: Inferred 'add_dft_control_points  
// top_rtl1_tessent_bscan_logical_group_DEF_inst/gpio_30_AuxInEn  
// -dft_signal_source_name ltest_en' because the DFT signal 'edt_update'  
// is sourced by an auxiliary data input pin.
```

report_dft_signals// Existing and to be created DFT signals

```
// =====  
// -----  
// Name          Status      Origin      Type          Location  
// -----  
// edt_update    Existing    User added  Port          gpio[30] -> DEF_inst/gpio_30_AuxIn  
// ext_ltest_en  Existing    User added  IJTAG port    gpio[33] -> gpio33/C  
// ltest_en      To be created User added  IJTAG register  
// scan_en       Existing    User added  Port          gpio[32] -> DEF_inst/gpio_32_AuxIn  
// test_clock    Existing    User added  Port          gpio[31] -> DEF_inst/gpio_31_AuxIn
```

Example 6

The following example creates one `static_dft_en` with ATPG control and one without ATPG control.

```
add_dft_signals x_bounding_en -add_hold_scan_cell on  
add_dft_signals mcp_bounding_en -source_node {mcp_bounding_en}
```

Note

 The “`static_dft_en`” generic term is used to represent any of the supported DFT signals in the list specified in “`-add_hold_scan_cell {on | off | auto}`”.

Neither of the `static_dft_en` signals is directly controlled by a TDR. The `mcp_bounding_en` signal was created from a source node. The `node_name` of `x_bounding_en` indicates that it is controlled by the inserted logic circuit. The original source node location and its type are

reported under the `unmapped_node_name` and `unmapped_type` properties respectively. The `“add_hold_scan_cell”` field appears under `Core(module_name)/DesignInfo/StaticDftSignals/StaticDftSignal(static_dft_e)`.

Figure 3-11. Holding Scan Cell Without Disable

Example 7

This example shows a set of commands that register a user-defined static DFT signal, which can be used as a holding scan cell deactivation signal. Then it adds a DFT signal with a holding scan cell.

```
register_static_dft_signal_names xbe_hold_scan_cell_disable \
-default_value 0 -reset_value 0
add_dft_signals x_bounding_en -add_hold_scan_cell on \
-hold_scan_cell_disable xbe_hold_scan_cell_disable
```

add_drc_violation

Context: dft, patterns

Mode: analysis

Adds a DRC violation to the list of DRC violations for a given DRC rule.

Usage

```
add_drc_violation itcl_object_instance_name [-of_type drc_name]
```

Description

This command is used to create a new DRC violation. The main argument of the command, *itcl_object_instance_name*, is the name of an object of an ITCL class containing a set of prescribed methods. The prescribed and required list of methods are `display`, `report`, `get_location`, and `set_simulation_context`. The Tessent Shell tool comes with a built-in `DrcViolation` ITCL class that provides these methods. The body of the class and the method are provided below. The likely hood that you ever need to write your own class is very low as this class is very flexible and complete. For example, if you wanted your `display` method to create a configuration tree instead of displaying logic in the schematic, then you would derive a new class from the `DrcViolation` and replace the “display” method with the method you create.

The `-of_type` argument is typically not used either as it defaults to the *drc_name*, which invokes the proc that calls the `add_drc_violation` command. As the `add_drc_violation` command is normally used in a proc referred by the “[register_drc -drc_proc](#)” command, it automatically inherits its *drc_name* from the caller.

You import the ITCL class into your namespace using the following command:

```
namespace import ::mentor::DrcUtilities::*
```

If you wanted to derive a new class to replace the body of a portion of the method, you would use the following:

```
itcl::class MyDrcViolation {
    inherit DrcViolation

    #Replaced methods
    ...
}
```

Refer to examples in the [register_drc](#) command description section for multiple example usages of the class. As shown in those examples, you use this to create an object of the class as follows:

```
set violation [DrcViolation #auto]
```

You then use the `dict_set` method to populate the information as shown in the code block as follows. If you want to show two paths at the same time, you can also populate the `side1` data. The `$path_to_tagged_objects` is a list of collections of paths. The paths are typically the ones

created by the “[trace_flat_model](#) -store_paths_to_tagged_objects” switch. The permitted values for the path_direction are forward and backward. If the \$path_to_tagged_objects contains just one element, you do not need to specify the direction of the path. The \$msg_list variable contains a Tcl list of strings that represent the message that is displayed when the [analyze_drc_violation](#) or the [report_drc_rules](#) commands are run. A new line is inserted between each element of the message_string_list:

```
$violation dict_set list_of_paths side0 [list $path_to_tagged_objects]
$violation dict_set path_direction side0 backward
$violation dict_set start_callout_string side0 $start_callout_string
$violation dict_set end_callout_string side0 $end_callout_string
$violation dict_set message_string_list $msg_list
```

Once you have finished configuring the ITCL object, you add it as a DRC violation using the following command:

```
add_drc_violation [namespace current]::$violation
```

Below is the source code defining the DrcViolation as it existed when this documentation was written. You can always see the current list of methods or the implementation of each of the methods by issuing the following commands.

```
info class methods ::mentor::DrcUtilities::DrcViolation
info class definition ::mentor::DrcUtilities::DrcViolation display
```

Notice the use of the environment variable “DrcViolation.echo_commands” and “DrcViolation.no_run_commands” in the display method. If you set the environment variable “DrcViolation.echo_commands” to 1 using the setenv command in your command shell or within the Tesselent Tcl shell, the commands used to display the violation are echoed in the transcript. If you set the environment variable “DrcViolation.no_run_commands” to 1, the command does not run. This is useful to create a regression suite where you can “goldenize” the echoed display commands in the transcript and make sure your custom DRC continues to display the right information without actually having to run the GUI and look at the result.

```

        }
    }
}
}
}

```

Arguments

- *itcl_object_instance_name*

A required string containing the name of an object of an iTcl class. As described above, the iTcl class must have a prescribed set of required methods. Refer to the description above for a description of those methods and the description of the built-in DrcViolation class that you can use for your custom DRC violation.

- `-of_type drc_name`

An optional switch-value pair used to specify the DRC name for which the violation belongs. The `-of_type` argument is typically not used either as it defaults to the `drc_name`, which invoke the proc that called the `add_drc_violation` command. As the `add_drc_violation` command is normally used in a proc referred by the “[register_drc](#) -drc_proc” switch, it automatically inherits its `drc_name` from the caller.

Examples

The following example usage of the `add_drc_violation` command is taken from one of the many examples shown in the [register_drc](#) command examples. The built-in `DrcViolation` class is used to create the `$drc_violation` object. The `dict_set` method is used to configure its data. After that the `add_drc_violation` command is issued to create the violation.

```
if {[sizeof_collection $multi_input_gates] > 0} {
  append_to_collection multi_input_cells \
    [get_instances -of_gate_pins $multi_input_gates -silent] -unique
  set multi_input_cell_count [sizeof_collection $multi_input_cells]
  set violation [DrcViolation #auto]
  $violation dict_set list_of_paths side0 \
    [list $path_to_tagged_objects]
  $violation dict_set path_direction side0 backward
  $violation dict_set start_callout_string side0 \
    "PO with path to PI with multi input gates along the path"
  $violation dict_set end_callout_string side0 "PI in fanin of PO"
  set start_port [index_collection $path_to_tagged_objects 0]
  set end_port [index_collection $path_to_tagged_objects \
    [expr [sizeof_collection $path_to_tagged_objects] - 1]]
  lappend msg_list "The output port '[get_single_name $start_port]'  
has a combinational path from the input port '[get_single_name $end_port]'"
  lappend msg_list "but the path is not a pure feed-through as the path  
crosses $multi_input_cell_count multi-input cells:"
  set cnt 1
  set max 3
  foreach_in_collection multi_input_cell $multi_input_cells {
    if {$cnt > $max} {
      lappend msg_list "  ..."
      break
    }
    lappend msg_list "  [get_single_name $multi_input_cell]"
    incr cnt
  }
  $violation dict_set message_string_list $msg_list
  add_drc_violation [namespace current]::$violation
}
```

add_edt_blocks

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Creates an arbitrary identifier for an EDT block and applies certain subsequent commands only to that block.

Usage

add_edt_blocks *block_name*

Description

This command defines a string, referred to as the block name or block tag, as the identifier for an EDT block instantiated in a design netlist and simultaneously restricts the applicability of certain subsequent commands to that block. Restricting the applicability of these commands to a particular EDT block is referred to as setting or changing the EDT context, and the EDT block on which context-sensitive commands currently operate is referred to as the current EDT block. The current EDT block remains the sole target of the context-sensitive commands until you delete its definition using the [delete_edt_blocks](#) command or change the context to a different EDT block using [set_current_edt_block](#) or another add_edt_blocks command.

You must use this command to define a unique name for an EDT block prior to defining its attributes using context-sensitive commands. The [add_scan_chains](#) command, EDT-specific commands that define attributes for a given block, and some reporting commands are presently the only context-sensitive commands. All other commands (set_system_mode, create_patterns and report_statistics for example) apply to the entire netlist.

If multiple EDT blocks are defined and none of them is specified as the current EDT block, subsequent context-sensitive commands that define attributes for a given block (“[set_edt_options](#) -channels” for example) returns an error. This can happen if you add multiple EDT blocks, then delete the one that is the current EDT block.

For more information about EDT blocks or the modular Tessent TestKompress flow, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- *block_name*

A required string that specifies a name to use for uniquely identifying a specific EDT block instantiated within a netlist. The name of the block must begin with an alphabetic character and contain only alphabetic characters, numeric characters, and the underscore (a-zA-Z0-9_). Consecutive underscores are not permitted. Underscores cannot appear as the first or last character of the identifier. The block_name is independent of the module and instance names used in the netlist. Escaped identifiers are not permitted.

Examples

Example 1

The following example defines the block name, “my_core1_block” for an EDT block that contains four scan chains. The tool determines the EDT block to associate with this name from the pin pathnames specified in the [add_scan_chains](#) commands that follow the `add_edt_blocks` command.

```
add_edt_blocks my_core1_block
# my_core1_block is the current EDT block.
...
add_scan_chains -internal core1_chain1 grp1 /edt_top_core1/cpu1_i/edt_si1 \
    /edt_top_core1/cpu1_i/edt_so1
add_scan_chains -internal core1_chain2 grp1 /edt_top_core1/cpu1_i/edt_si2 \
    /edt_top_core1/cpu1_i/edt_so2
add_scan_chains -internal core1_chain3 grp1 /edt_top_core1/cpu1_i/edt_si3 \
    /edt_top_core1/cpu1_i/edt_so3
add_scan_chains -internal core1_chain4 grp1 /edt_top_core1/cpu1_i/edt_si4 \
    /edt_top_core1/cpu1_i/edt_so4
```

Example 2

The following example defines two more block names, “my_core2_block” and “my_core3_block”, then displays a list of the current block names. The display indicates subsequent context-sensitive commands apply only to the EDT block named “my_core3_block”.

```
add_edt_blocks my_core2_block
# my_core2_block is the current EDT block.
...
add_scan_chains -internal core2_chain1 grp1 /edt_top_core2/cpu3_i/edt_si1 \
    /edt_top_core2/cpu3_i/edt_so1
add_scan_chains -internal core2_chain2 grp1 /edt_top_core2/cpu3_i/edt_si2 \
    /edt_top_core2/cpu3_i/edt_so2
...
add_edt_blocks my_core3_block
# my_core3_block is the current EDT block.
...
add_scan_chains -internal core3_chain1 grp1 /edt_top_core3/cpu7_i/edt_si1 \
    /edt_top_core3/cpu7_i/edt_so1
...
add_scan_chains -internal core3_chain8 grp1 /edt_top_core3/cpu7_i/edt_si8 \
    /edt_top_core3/cpu7_i/edt_so8

report_edt_blocks
// my_core1_block
// my_core2_block
// my_core3_block    (current block)
```

Example 3

The following example removes from the tool's internal database, the data for the EDT block named "my_core3_block", making it unavailable for use with the [set_current_edt_block](#) command.

```
delete_edt_blocks my_core3_block
```

```
// Block deleted. No EDT block now selected as current block.
```

```
report_edt_blocks
```

```
// my_core1_block  
// my_core2_block
```

[set_current_edt_block](#)

add_edt_configurations

Context: dft -edt

Mode: setup

Sets up EDT logic with two compression configurations.

Usage

add_edt_configurations *config_name*

Description

The add_edt_configurations command creates a compression configuration and applies subsequent EDT channel specifications to the configuration. Up to two compression configurations can be defined for a design block.

In a multi-block design flow, you can define the compression configurations at the top-level integration and all subsequently added blocks inherit the defined compression configurations. The configuration parameters need to be set for each block context.

Note

 When two configurations are specified and one of the configurations is missing an input/output channel parameter, it inherits the needed value from the other configuration. You can override this feature by explicitly specifying the channel configuration.

For more information on setting up two compression configurations, see the “[Defining Dual Compression Configurations](#)” section in the *Tessent TestKompress User’s Manual*.

Arguments

- *config_name*
A required string that specifies a name for the compression configuration.

Examples

The following example shows a dofile that creates two configurations for a single block.

```
# edt_ip_creation.do
#
# Dofile for EDT logic creation
dofile scan_chain_setup.dofile

# Set up EDT configurations
set_edt_options -location internal
add_edt_configurations my_sys_test_config
set_edt_options -input_channels 4 -output_channels 2
add_edt_configurations my_wafer_test_config
set_edt_options -input_channels 5 -output_channels 4

# Set bypass pin
set_edt_pins bypass my_bypass_pin

# Set edt configuration pin
set_edt_pins configuration my_configuration_pin
set_system_mode analysis

# Report and write EDT logic.
report_edt_configurations -all # Report configurations for all blocks.
report_edt_pins # Report all pins including compression configuration
# specific pins.
write_edt_files created -verilog -replace # Create dofiles and
# test procedure files for both the configurations and the bypass mode

write_design -output_file created_edt_top_rtl.v -replace # Write the
# current design in Verilog format to the file created_edt_top_rtl.v.
```

add_false_paths

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Defines false paths in the design. False paths are paths that cannot be activated in the design's functional (at-speed) mode of operation. You would typically determine them as a part of static timing analysis, prior to ATPG.

Usage

```
add_false_paths
  {[-From source_node... | -FROM_Clock clock_signal_name...]
  [-TO sink_node... | -TO_Clock clock_signal_name...]
  [{-THrough through_node...}...]} | -Cross_clock_domains
  [-Hold] [-Setup] [-MAX_Skew {HALf_cycle | ONE_cycle | MULtiple_cycles}]
```

Description

If a false path is sensitized for an at-speed test during ATPG, invalid capture responses can occur at certain scan cells and POs with resulting invalid capture responses at the end points of the false path. This can cause simulation mismatches when you verify the patterns in a timing-based simulator. By defining the false paths, you enable the tool to identify the invalid capture responses. Once identified, the tool masks these responses (modify them to X) in the resultant patterns so they are not the source of simulation mismatches.

For additional information, refer to “[Pattern Failures Due to Timing Exception Paths](#),” in the *Tessent Scan and ATPG User's Manual*.

You can use the “[set_timing_exceptions_handling -allow_invalid_pin_names on](#)” command to enable the add_false_paths command to issue warnings instead of errors when defined objects are not found.

Arguments

Tip

 When using the following arguments, you can include any number of asterisks (*) in pin or instance pathnames. The command treats an asterisk as a wildcard character, enabling you to use it to match many pathnames in the design.

- -From *source_node...*

An optional switch and repeatable string pair that specifies the starting point of a false path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the output pins of the instance to be starting points. For a clock PI, the tool considers the outputs of all the non-transparent latches, flip-flops and RAMs associated with the clock PI to be starting points. The tool considers a pin pathname to be that of an internal clock pin if its fanout

reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

By default, if a specified source node does not translate to an internal gate, the tool transcribes an error message, and not add the false path definition to its internal database. If you issue the “[set_timing_exceptions_handling -allow_invalid_pin_name on](#)” command, the tool reports a warning and adds the false path definition.

- **-FROM_Clock** *clock_signal_name...*

An optional switch and repeatable string pair that specifies the starting point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of a clock signal and considers the outputs of all non-transparent latches, flip-flops and RAMs associated with this clock signal to be starting points.

By default, if a specified clock signal name does not translate to an internal gate, the tool transcribes an error message and not add the false path definition to its internal database. If you issue the “[set_timing_exceptions_handling -allow_invalid_pin_name on](#)” command, the tool reports a warning and adds the false path definition.

- **-TO** *sink_node...*

An optional switch and repeatable string pair that specifies the end point of a false path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the input pins of the instance to be end points. For a clock PI, the tool considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with the clock PI to be end points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

By default, if a specified sink node does not translate to an internal gate, the tool transcribes an error message and does not add the false path definition to its internal database. If you issue the “[set_timing_exceptions_handling -allow_invalid_pin_name on](#)” command, the tool reports a warning and adds the false path definition.

Note

 For a 2-port latch with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “`add_false_paths... -to CLK2`” would define paths with an end point at D2.

- **-TO_Clock** *clock_signal_name...*

An optional switch and repeatable string pair that specifies the end point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of an internal clock signal and considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with this clock to be end points.

By default, if a specified clock signal name does not translate to an internal gate, the tool transcribes an error message and does not add the false path definition to its internal

database. If you issue the “[set_timing_exceptions_handling -allow_invalid_pin_name on](#)” command, the tool reports a warning and adds the false path definition.

- `{-Through through_node...}`...

An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the false path must pass. A valid through node is a pin or instance pathname. Clock PIs are not supported as through nodes and the tool makes no attempt to determine if a pin pathname is that of an internal clock pin.

When you use multiple `-Through` arguments, the tool considers their order left-to-right in the command string to be the order in which a signal would pass through the nodes on the specified path. For example, the following false path specification:

```
add_false_paths -from A -through B C -through D E -to F
```

specifies all paths that start from A, pass through either B or C, then pass through D or E, and end at F. If you do not use the `-Through` argument when specifying a path, the tool considers all paths from the specified starting points to the specified end points to be false paths.

By default, if a through node does not translate to an internal gate, the tool transcripts an error message and does not add the false path definition to its internal database. If you issue the “[set_timing_exceptions_handling -allow_invalid_pin_name on](#)” command, the tool reports a warning and adds the false path definition.

- **-Cross_clock_domains**

A switch that adds hold time false paths between all clocks.

Note

You cannot use this switch in Setup mode.

Use this switch instead of multiple `add_false_paths` command instances using the `-TO_Clock` and `-FROM_Clock` switches to specify each path and direction between the clocks. Refer to Example 7.

- **-Hold**

An optional switch that evaluates the false path for hold time exceptions.

By default, the tool considers the hold time false path only when the `-from flop` and the `-to flop` are updated at the same clock edge for most paths. This behavior matches the “same edge” interaction of the domain clock setting. The exception is when you use the “`add_false_paths -cross_clock_domains`” or the false paths derived from asynchronous clock groups defined in SDC files. For such cross clock domain false paths, the tool assumes that the clock skew can be multiple cycles.

When you define a false path without the `-hold` and the `-setup` options, the default is to consider the false path with both the hold and setup time exceptions.

add_false_paths

- -Setup

An optional switch that evaluates the false path for setup time exceptions.

For more information, refer to “[Types of Timing Exception Paths](#)” in the *Tessent Scan and ATPG User’s Manual*.

- -MAX_Skew

An optional switch that specifies the maximum clock skew for the hold time exception for this false path. This option overrides the global -max_skew specified by the set_timing_exceptions_handling command.

HALf_cycle

Specifies half cycle as the maximum clock skew. This is the default value for this option, unless -cross_clock_domains is specified, in which case, the max skew is multiple cycle.

ONE_cycle

Specifies one cycle as the maximum clock skew.

MULTiple_cycles

Specifies multiple cycles as the maximum clock skew.

Examples

Example 1

The following example creates three false paths definitions, then reports all current false path definitions:

```
add_false_paths -from /my_design/a /my_design/b -through /my_design/u1
add_false_paths -to /my_design/c
add_false_paths -through /my_design/u24 /my_design/u25
report_false_paths -all

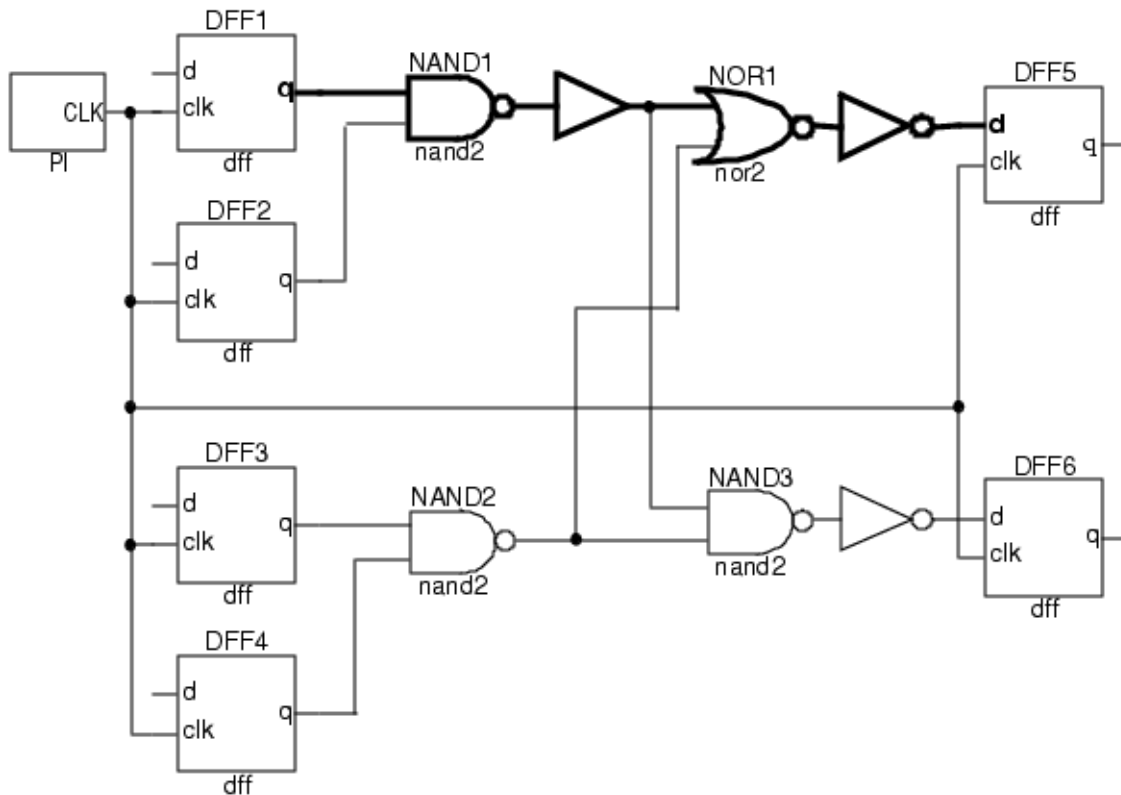

// False Path -from /my_design/a /my_design/b -through /my_design/u1
// False Path -to /my_design/c
// False Path -through /my_design/u24 /my_design/u25
// Total reported paths = 3
```

Example 2

The following example defines the path highlighted in [Figure 3-13](#) as a false path:

```
add_false_paths -from DFF1/q -to DFF5/d
```

Figure 3-13. Example of a False Path to be Defined

Here are four more ways you could define the same false path:

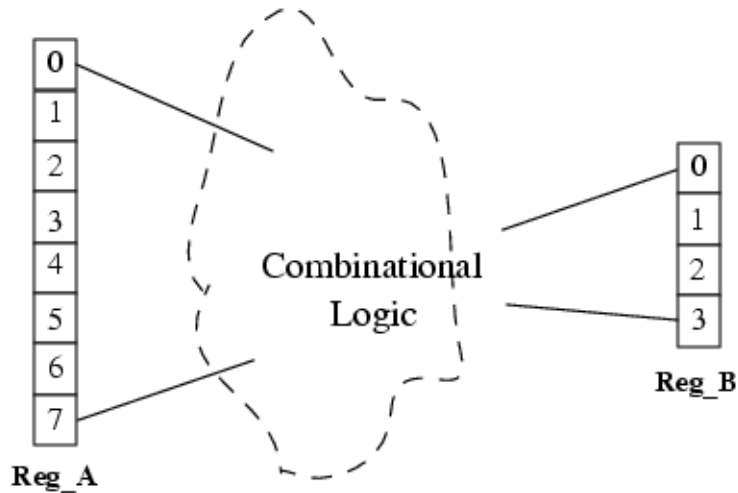

```
add_false_paths -from DFF1/q -through NOR1 -to_clock CLK
add_false_paths -from DFF1/clk -to DFF5/d
add_false_paths -from DFF1/q -to DFF5/clk
add_false_paths -from DFF1/clk -to DFF5/clk
```

Example 3

Referring to [Figure 3-14](#), the following example defines as false paths all the paths that start from Reg_A[0...7] and end at Reg_B[0...3]:

```
add_false_paths -from Reg_A -to Reg_B
```

Figure 3-14. Example Circuit for Defining False Paths

Example 4

This example defines as false paths (in [Figure 3-14](#)) all the paths that start from Reg_A[0] and end at Reg_B[0...3]:

```
add_false_paths -from Reg_A[0] -to Reg_B
```

Example 5

This example defines as false paths all the paths that start from Reg_A[0] or Reg_A[3] and end at Reg_B[2]:

```
add_false_paths -from Reg_A[0] Reg_A[3] -to Reg_B[2]
```

Example 6

The remaining six examples describe signal matches for various sample pin pathnames specified using the asterisk (*) wildcard character. The pathnames are based on the following design:

```
module top(...);  
  Input ...;  
  Output...;  
  ...  
  foo u1(...);  
  ...  
endmodule;module foo(...);  
  Input...;  
  Output...;  
  ...  
  staticRegister I_reg_1(.D1(...), .C1(...), .Z(...));  
  staticRegister I_reg_2(.D1(...), .C1(...), .Z(...));  
  staticRegister I_reg_3(.D1(...), .C1(...), .Z(...));  
  staticRegister F_reg_1(.D1(...), .C1(...), .Z(...));  
  staticRegister F_reg_2(.D1(...), .C1(...), .Z(...));  
  ...  
endmodule;
```

1. The signal name `/u1/*reg_1/D1` maps to signals `/u1/I_reg_1/D1` and `/u1/F_reg_1/D1`.
2. The signal name `/u1/I_reg*/D1` maps to signals `/u1/I_reg_1/D1`, `/u1/I_reg_2/D1` and `/u1/I_reg_3/D1`.
3. The signal name `/u1/*reg*/Z` maps to signals `/u1/I_reg_1/Z`, `/u1/I_reg_2/Z`, `/u1/I_reg_3/Z`, `/u1/F_reg_1/Z` and `/u1/F_reg_2/Z`.
4. The signal name `/u1/F_reg_2/*` maps to signals `/u1/F_reg_2/D1`, `/u1/F_reg_2/C1` and `/u1/F_reg_2/Z`.
5. The signal name `/u1/F*/*1` maps to signals `/u1/F_reg_1/D1`, `/u1/F_reg_1/C1`, `/u1/F_reg_2/D1` and `/u1/F_reg_2/C1`.
6. The signal name `/u1/I*1/C1` maps to signal `/u1/I_reg_1/C1`.

Example 7

Assume the design contains two defined clocks: `clk1` and `clk2`. The following command adds hold time false paths between `clk1` and `clk2`:

```
add_false_paths -cross_clock_domains -hold
```

The above command is equivalent to the following two commands:

```
add_false_paths -from_clock clk1 -to_clock clk2 -hold  
add_false_paths -from_clock clk2 -to_clock clk1 -hold
```

add_fault_sites

Context: dft -edt, patterns -scan

Mode: analysis

Automatically adds fault site definitions for library cells that do not have UDFM definitions.

Usage

add_fault_sites {-ALI | -UNDEFINED_Cells} [-VERBose]

Description

The add_fault_sites command automatically adds port fault site definitions for library cells that are not covered by the current UDFM definitions so that you do not have to add them manually to the UDFM file. In order to distinguish those added definitions and resulting fault sites in report functions, the added definitions are collected in the UDFM type “auto-inserted-faults.”

After you’ve added the fault sites, the [add_faults](#) command adds static or delay faults to those locations, as specified by the “[set_fault_type udfm](#)” command.

Note

The add_fault_sites command works only for the fault type UDFM, and is available only after you read a UDFM fault file and before you create the fault list.

For more information about UDFM, refer to “[About User-Defined Fault Modeling](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **-ALI**
A required switch that automatically adds UDFM definitions for all undefined (uncovered) port fault sites, including PI’s and PO’s. The fault sites affected by this switch include all those affected by the -Undefined_Cells switch plus remaining port fault site definitions for existing cells and modules, as well as additional port fault sites without this scope.
- **-UNDEFINED_Cells**
A required switch that automatically adds UDFM definitions for cell port fault sites in undefined (uncovered) cells or modules.
- **-VERBose**
An optional switch that displays additional information about each added UDFM definition.

Examples

The following example shows the effect of adding fault site definitions for all library cells not covered by UDFM definitions:

```
read_fault_sites /home/design/c090_std/c090_std.udfm
```

```
// Reading UDFM File: /home/design/c090_std/c090_std.udfm
// UDFM definitions read: Total=3, Cells=1, Modules=2, Instances=0,
// No Match=0
```

report_fault_sites -undefined_cells

```
// Report of cells not defined by UDFM
//
// Cell Name   Instances
// -----
// M1          2
// M2          1
// u_mux2      1
// -----
```

add_fault_sites -undefined_cells

```
// 3 UDFM definition(s) for uncovered cells have been added
```

add_faults -all

```
// Number added faults=56 instances considered=7 not-considered=3
```

add_faults

Context: dft -edt, dft -test_points, patterns -scan

Mode: analysis

Adds faults to the current fault list, discards all patterns in the current test pattern set, and sets all faults to undetected.

Usage

```
add_faults fault_model_specific_options [power_aware_options] [ -KEEP_Patterns ]
  [{> | >>} file_pathname]
```

Stuck/Transition/Toggle/Iddq Fault Model Options:

```
[ -All | { object_expression...
  [-PIN | -INstance | -MODule [-PIN module_pin_pathname ...]] }
| {-CLOCK_domains {ALL | clock_pathname...} [-NO_EQUivalent_clocks]
  [-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains]
  [-exclude_constrained_clock_domains]}
| {-CAPture_procedures {ALL | capture_procedure_name...}} ]
[-Stuck_at {01 | 0 | 1}] [-VERBose]
```

UDFM Fault Model Options:

```
[ -All | {object_expression... [-INstance]}
| {-CLOCK_domains {ALL | clock_pathname...} [-NO_EQUivalent_clocks]
  [-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains]
  [-exclude_constrained_clock_domains]}]
[-UDFM_type name] [-CELL name] [-MODule name] [-FAULT name] [-VERBose]
```

Bridge Fault Model Options:

```
[ -All | {bridge_name... -NAME} | {net_pathname... -SINGLE}
| {instance_name... -SINGLE} |
{-CLOCK_domains {ALL | clock_pathname...} [-NO_EQUivalent_clocks]
  [-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains]
  [-exclude_constrained_clock_domains]}
| {-CAPture_procedures {ALL | capture_procedure_name...}} ]
```

Path Delay Fault Model Options:

```
[name_of_delay_path... | -All] [-Both | -Rise | -Fall]
```

Power-Aware Options (applicable only after you have loaded CPF/UPF power data):

```
[-ON_domains | -OFF_domains | {-POWER_domains {domain_name ...}}]
[-ISolation_cells] [-LEvel_shifters] [-REtention_cells]
```

Description

The `add_faults` command adds faults to the current fault list—either all faults specific to the fault model, or faults you specify by an object expression. By default, it also discards all patterns in the current test pattern set and sets all faults to undetected (specifically, to the UC category).

When you enter Setup mode, the tool deletes all faults from the current fault list. Furthermore, if you change the fault type, it also deletes all faults. The power-aware options add faults based on power domains and power features after you have loaded a CPF or UPF file.

You cannot add faults for clock domains, capture procedures, and specific objects or paths within the same command instance. Use a separate command instance for each.

When the fault mode is “uncollapsed” (the invocation default), the tool adds all possible faults to the list. If you change the fault mode to “collapsed” with the `set_fault_mode` command, only one instance of any given fault is added, ignoring any equivalent faults.

Arguments

- **-KEEP_Patterns**

An optional switch that preserves the current test pattern set and maintains the status of the current faults while adding faults. The default behavior is to discard the current test pattern set and set all faults to undetected.

- **-All**

A required switch that adds all faults, depending on the fault model.

- **Bridge Faults** — Adds all previously loaded bridge entries to the internal fault list. This is the default behavior.
- **UDFM Faults** — Adds faults for all previously loaded UDFM fault sites to the internal fault list. This is the default behavior.
- **Non-Bridge Faults** — Adds all faults on all model, netlist primitive, and top module pins. The setting of the `set_internal_fault` command affects the behavior of this switch. If you have not specified “`set_internal_fault on`”, the switch adds only faults residing on the boundaries of library cells. If you have specified “`set_internal_fault on`”, the `-All` switch adds faults that reside on the inputs and outputs of gates within library cells. For more information about fault locations, refer to “[Fault Locations](#)” in the *Tessent Scan and ATPG User’s Manual*.

- ***name_of_delay_path***

A required, repeatable string that specifies the names of the delay paths whose faults you want to add to the current fault list. The name must correspond to the name of a delay path defined in [the path definition file](#).

- **-Both | -Rise | -Fall**

An optional switch that specifies which faults to add for each path already added with the `read_fault_sites` command. Use these switches for path delay faults only.

- Both** — Adds both the slow-to-rise and slow-to-fall faults. This is the default.
- Rise** — Adds only the slow-to-rise faults.
- Fall** — Adds only the slow-to-fall faults.

- ***object_expression***

A required, repeatable string that specifies a list of instances or pins whose faults you want added to the current fault list. For UDFM, you can specify only instances. You can use any number of asterisk (*) and question mark (?) wildcard characters in the expression.

Instance pathnames must be Tessent Cell library cell instances. Pin pathnames must be Tessent Cell library cell instance pins, also referred to as design level pins. If the object expression specifies a pin within an instance of a Tessent Cell library model, the tool ignores it. By default, the tool matches pin pathnames first. If it does not find a pin pathname match, the tool next tries to match instance pathnames. Force the tool to match only pin pathnames or only instance pathnames by including the -PIN or -INstance switch after the *object_expression*.

- -PIN

An optional switch that specifies to use the preceding object expression to match only pin pathnames; the tool adds faults for all the pins matched.

- -INstance

An optional switch that specifies to use the preceding object expression to match only instance pathnames; the tool adds faults for all the pins on the instances matched.

- -MODule [-PIN *module_pin_pathname ...*] (Stuck/Transition/Toggle/Iddq only)

A switch that specifies to interpret the *object_expression* argument as a module pathname. All instances of the module are affected. You can use the asterisk (*) and question mark (?) wildcards for the *object_expression* argument, and the tool adds the fault for all matching modules or library models.

When you follow the -Module switch with the optional -PIN switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given *object_expression* and adds faults for every pin specified in *module_pin_pathname* list.

- ***bridge_name***

A required, repeatable string that specifies bridge names whose bridge faults you want added to the current fault list.

- ***net_pathname***

A required, repeatable string that specifies single net names whose bridge faults you want added to the current fault list.

- ***instance_name***

A required, repeatable string that specifies instances names whose bridge faults you want added to the current fault list.

- -NAME

An optional switch that specifies all entered strings are bridge names.

- **-SINGLE**

An optional switch that specifies all the entered strings are either a single net or instance. The tool searches for a net first. If it cannot find a corresponding net, the tool searches for a corresponding instance.

If the string specifies a net, the tool adds faults to the fault list for each bridge entry associated with the net.

If the string specifies an instance that contains a non-dominant net specified in a bridge entry, the tool adds associated faults to the fault list.

- **-CLOCK_domains {ALL | *clock_pathname*...}**

A required switch and literal or repeatable string pair that specifies a list of clocks that the tool uses to decide the faults it adds to the fault list, subject to the following requirements:

- **Static Faults** — The tool adds a fault to the fault list if it can be captured by any clock in the specified list of clocks or any of its equivalent clocks.
- **Transition Faults** — The tool adds a fault to the fault list if one of the following is true:
 - i. The launch and capture clock are the same clock from the specified list of clocks
 - ii. The launch and capture clock are synchronous clocks from the specified list of clocks
 - iii. The launch or capture clock from the specified are equivalent clocks

When you use this switch, the tool ignores the constraint values implied in the data path when adding faults in the data path. However, the tool still considers the constraint value for the clock cone tracing to determine the state element clock domain.

The argument choices are as follows:

ALL — A literal that specifies all the clocks in the design.

clock_pathname — A repeatable string that specifies individual clocks.

Note

A fault added using this switch might also be detectable by an unspecified clock.

- **-NO_EQUIvalent_clocks**

An optional switch that prevents the `-Clock_domains` switch from adding faults in equivalent clock domains.

- **-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains**

An optional switch used with `-Clock_domains` to instruct the tool to exclude the inter-clock faults for synchronous clocks. When you specify this switch, the tool considers only faults within clock domains when adding or deleting faults by clock domain.

- **-exclude_constrained_clock_domains**

An optional switch used with **-Clock_domains** to exclude the faults in constrained clock domains. By default, the command includes the faults in constrained clock domains when you run “**add_faults -clock_domains all.**”

- **-CAPture_procedures**{**ALL** | *capture_procedure_name...*}

A required switch and literal or repeatable string pair that specifies a list of enabled named capture procedures and directs the tool to add faults that are potentially detectable by any of the specified procedures. The argument choices are as follows:

ALL — A literal that specifies all enabled named capture procedures.

capture_procedure_name — A repeatable string that specifies a particular enabled named capture procedure.

For information about enabling named capture procedures, see the [set_capture_procedures](#) command description.

- **-Stuck_at** {01 | 0 | 1}

An optional switch and literal pair that specifies which stuck-at or transition faults to add to the fault list according to the following table:

	01 (default)	0	1
Stuck-At	stuck-at-0 stuck-at-1	stuck-at-0	stuck-at-1
Transition	slow-to-rise slow-to-fall	slow-to-rise	slow-to-fall

- **-Udfm_type** *name*

A switch and string pair that specifies a UDFM type. Use this switch to add faults associated with a specified UDFM type. The name string is case insensitive and may include any number of asterisk (*) and question mark (?) wildcard characters.

- **-CELL** *name*

A switch and string pair that specifies a library cell. Use this switch to add faults associated with a specified library cell. The name string is case insensitive and may include any number of asterisk (*) and question mark (?) wildcard characters.

- **-MODULE** *name (UDFM only)*

A switch and string pair that specifies a module. Use this switch to add faults associated with a specified module. The name string is case insensitive and may include any number of asterisk (*) and question mark (?) wildcard characters.

- **-FAULT *name* (UDFM only)**

A switch and string pair that specifies a UDFM fault name. The name string is case insensitive and can include any number of asterisk (*) and question mark (?) wildcard characters.

- **-VERbose**

By default, when you specify wildcard characters for instance (-INstance) or pin (-PIN) names, the tool outputs a summary message similar to the following:

```
// Note: Adding faults for 330 fault sites.
```

When you specify the optional -VERbose switch, the tool outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the > or >> redirection operators.

If you use actual instance or pin names instead of wildcards, then this switch has no effect.

- **> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- **>> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Power-Aware Options (applicable only after you have loaded CPF/UPF power data)

- **-ON_domains**

An optional switch that adds faults on all power-on domains.

- **-OFF_domains**

An optional switch that adds faults on all power-off domains.

- **-Power_domains {*domain_name* ...}**

An optional switch and repeatable string that adds faults on the specified power domains.

- **-Isolation_cells**

An optional switch that adds faults on all isolation cells.

- **-Level_shifters**

An optional switch that adds faults on all level shifters.

- **-REtention_cells**

An optional switch that adds faults on all retention cells.

Examples

Example 1

The following example adds all faults to the circuit so you can run an ATPG process:

```
set_system_mode analysis  
create_patterns
```

Example 2

The following example uses a prefix match to add faults only to pins on instances whose pathnames begin with “/u9/u2/LCT_reg”:

```
add_faults /u9/u2/LCT_reg*  
  
=== Found 16 design pins ===  
/u9/u2/LCT_reg_0_/A0  
/u9/u2/LCT_reg_0_/A1  
/u9/u2/LCT_reg_0_/S0  
/u9/u2/LCT_reg_0_/Y  
/u9/u2/LCT_reg_1_/A0  
/u9/u2/LCT_reg_1_/A1  
/u9/u2/LCT_reg_1_/S0  
/u9/u2/LCT_reg_1_/Y  
/u9/u2/LCT_reg_2_/A0  
/u9/u2/LCT_reg_2_/A1  
/u9/u2/LCT_reg_2_/S0  
/u9/u2/LCT_reg_2_/Y  
/u9/u2/LCT_reg_3_/A0  
/u9/u2/LCT_reg_3_/A1  
/u9/u2/LCT_reg_3_/S0  
/u9/u2/LCT_reg_3_/Y
```

Example 3

The following example uses the same prefix match as the preceding example but includes the -Instance switch:

```
delete_faults -all  
add_faults /u9/u2/LCT_reg* -instance  
  
=== Found 4 design instances ===  
/u9/u2/LCT_reg_0_  
/u9/u2/LCT_reg_1_  
/u9/u2/LCT_reg_2_  
/u9/u2/LCT_reg_3_
```

When you use the -Instance switch, the command lists the instances whose pins are faulted as a result of the wildcard character rather than listing each pin.

Example 4

The following example demonstrates how to use a wildcard in the second level of hierarchy:

```
add_faults /u9/*/LCT_reg_0_ -instance
```

```
=== Found 4 design instances ===  
/u9/u4/LCT_reg_0_  
/u9/u3/LCT_reg_0_  
/u9/u2/LCT_reg_0_  
/u9/u1/LCT_reg_0_
```

Example 5

The following example combines a wildcard character at the second level of hierarchy with a prefix match:

```
add_faults /u9*/LCT_reg* -instance  
  
=== Found 32 design instances ===  
/u9/u4/LCT_reg_0_  
/u9/u4/LCT_reg_1_  
/u9/u4/LCT_reg_2_  
/u9/u4/LCT_reg_3_  
/u9/u4/LCT_reg_4_  
/u9/u4/LCT_reg_5_  
/u9/u4/LCT_reg_6_  
/u9/u4/LCT_reg_7_  
/u9/u3/LCT_reg_0_  
/u9/u3/LCT_reg_1_  
/u9/u3/LCT_reg_2_  
...  
/u9/u2/LCT_reg_5_  
/u9/u2/LCT_reg_6_  
/u9/u2/LCT_reg_7_  
/u9/u1/LCT_reg_0_  
/u9/u1/LCT_reg_1_  
/u9/u1/LCT_reg_2_  
/u9/u1/LCT_reg_3_  
/u9/u1/LCT_reg_4_  
/u9/u1/LCT_reg_5_  
/u9/u1/LCT_reg_6_  
/u9/u1/LCT_reg_7_
```

Example 6

The following example adds only faults in the power domain named PD1:

```
add_faults -power_domain PD1
```

Example 7

The following example uses a prefix match to add faults to pins on instances whose pathnames begin with “/u9/u2/LCT_reg”, plus all level shifters in the design:

```
add_faults /u9/u2/LCT_reg* -level_shifters
```

Example 8

The following example adds intra_cell_bridges UDFM fault models associated with all library cells that start with “mux” to the current fault list.

```
add_faults -all -udfm_type intra_cell_bridges -cell mux*
```

add_faults

Example 9

The following example adds `intra_cell_bridges` UDFM fault models to the instance `my_module1_ins/my_module1_or02`. When you add a UDFM fault model, you do not need the `-instance` switch.

```
add_faults my_module1_ins/my_module1_or02 -udfm_type intra_cell_bridges
```

Example 10

The following example adds fault models to every module in the current fault list whose name begins with `adder`.

```
add_faults -all -module adder*
```

Example 11

The following example displays the fault value on the specified `gate_pin` after the `add_faults` command runs:

```
add_nofaults ha1/ddd/q -Pin -Stuck 1
add_nofaults ha1/ddd/clk -Pin -Stuck 0
add_nofaults ha1/ddd/d -Pin -Stuck 01
....
add_faults -all
....

foreach_in_collection i [get_gate_pins ha1/ddd/* ] {
    puts "[get_name_list$i] fault_site:[get_attribute_value_list$i-name fault_site]"
}

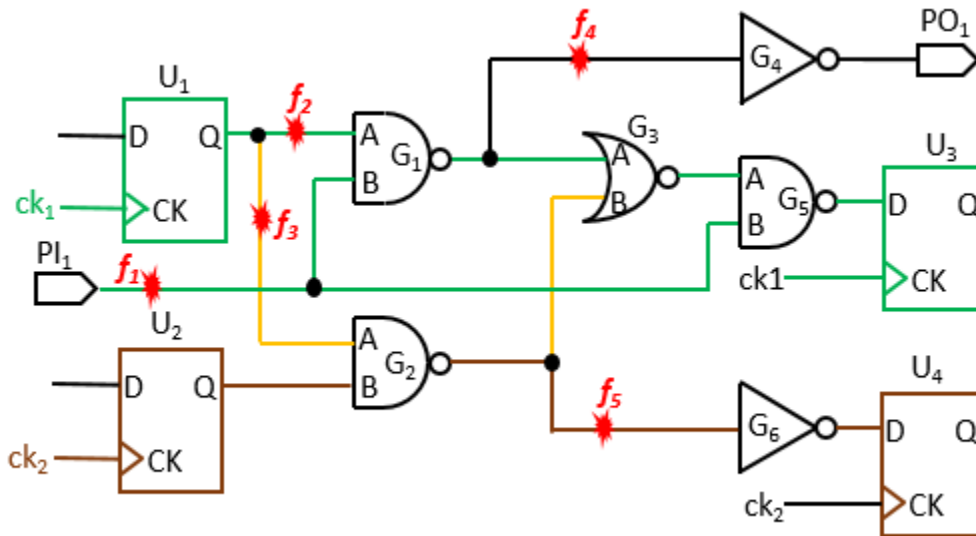

ha1/ddd/clk    fault_site: 1
ha1/ddd/d     fault_site: none
ha1/ddd/q     fault_site: 0
```

Example 12

The following example illustrates using the `-clock_domains` switch with stuck-at faults:

```
add_faults -clock_domains ck1 ck2
```

Figure 3-15. Static Fault

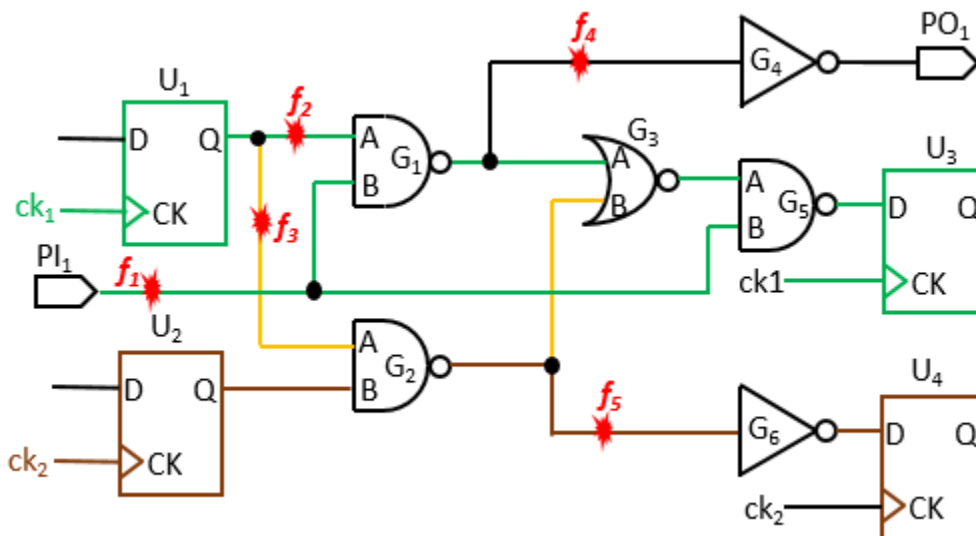

This adds the faults f_1 , f_2 , f_3 , and f_5 .

Example 13

For this example, assume that f_1 , f_2 , f_3 , f_4 , and f_5 are legitimate fault sites. Other pins are no-faulted. Use the `-clock_domains` switch with transition faults and without defining a synchronous clock group. In this case, `ck1` and `ck2` are incompatible.

```
add_faults -clock_domains ck1 ck2
```

Figure 3-16. Transition Fault - Incompatible Clocks

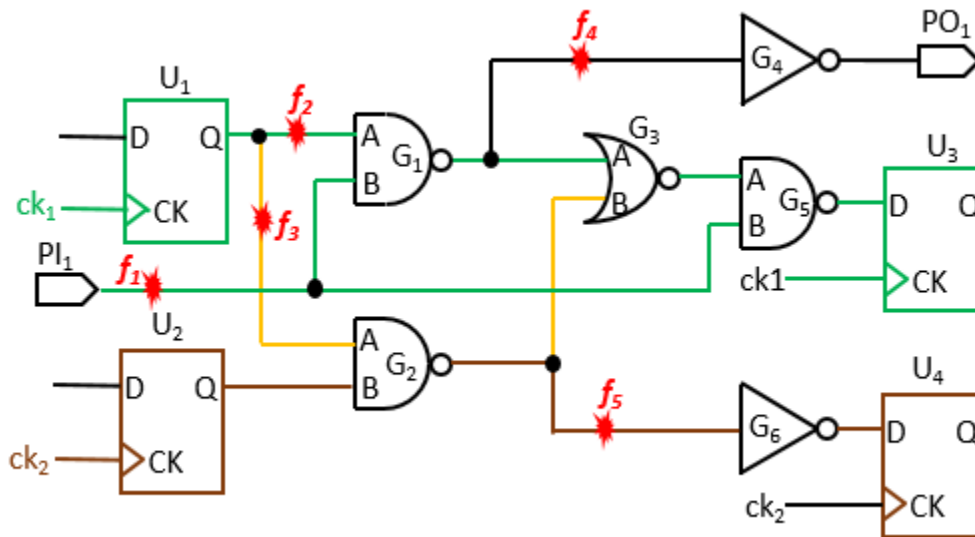

The added faults are f_2 , and f_5 . In this case, the command does not add f_3 because $clk1$ (launch clock) and $clk2$ (capture clock) are asynchronous.

Example 14

The following example illustrates using the `-clock_domains` switch with transition faults, after defining a synchronous clock group. In this case, $clk1$ and $clk2$ are compatible:

```
add_synchronous_clock_group {ck1 ck2}  
...  
add_faults -clock_domains ck1 ck2
```

Figure 3-17. Transition Fault - Compatible Clocks

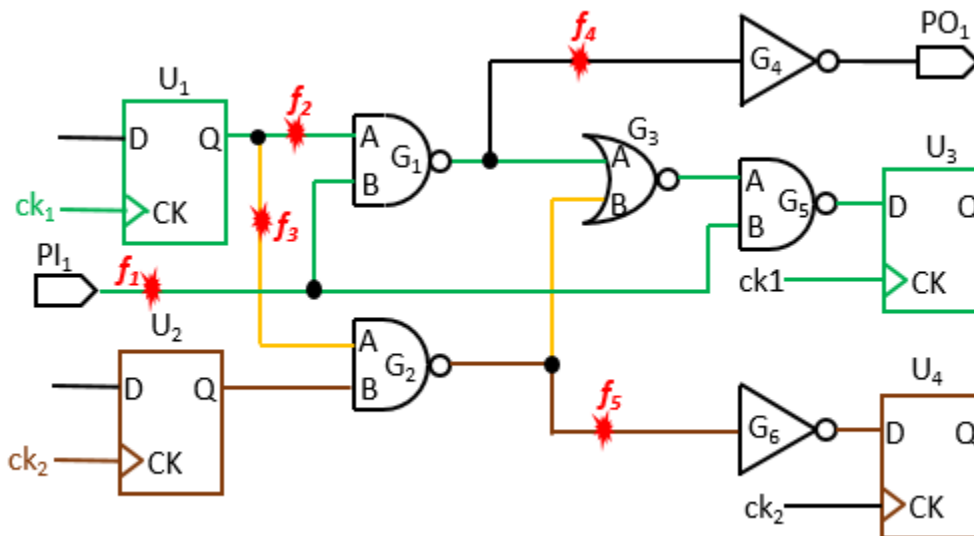

The added faults, launched and captured by $ck1$ and $ck2$, are f_2 , f_3 , and f_5 . You can use the `add_faults` option `-exclude_faults_between_synch_clock_domains` to exclude cross-domain faults, such as f_3 .

Example 15

For this example, assume that f_1 , f_2 , f_3 , f_4 , and f_5 are legitimate fault sites. Other pins are no-faulted. Use the `-clock_domains` switch with transition faults and without defining equivalent pins:

```
add_faults -clock_domains ck1
```

Figure 3-18. Transition Fault - No Equivalent Pins

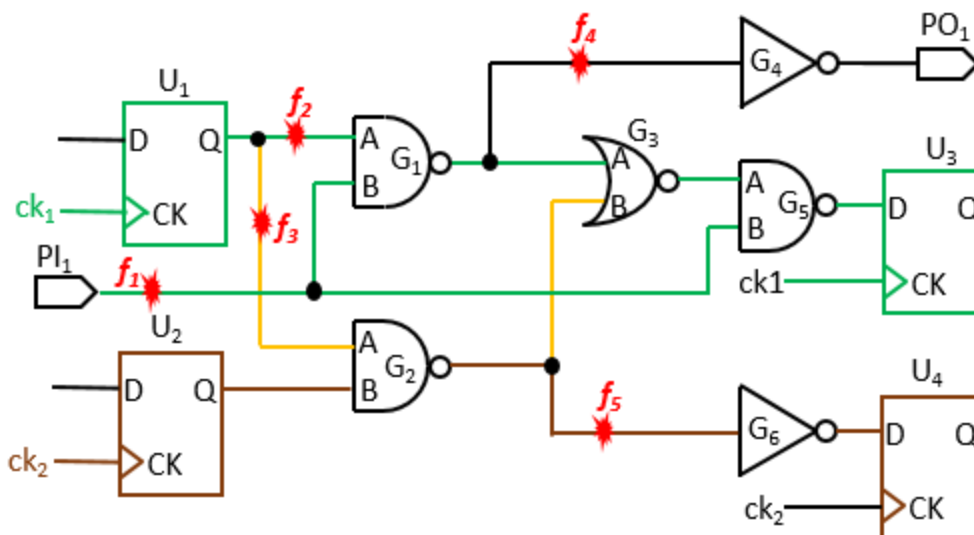

The added fault is f_2 .

Example 16

For this example, assume that f_1 , f_2 , f_3 , f_4 , and f_5 are legitimate fault sites. Other pins are no-faulted. Use the `-clock_domains` switch with transition faults and with pin equivalents defined for `ck1` and `ck2`:

```
add_input_constraints -equivalent ck1 ck2
...
add_faults -clock_domains ck1
```

Figure 3-19. Transition Fault - Equivalent Pins

add_faults

The added faults are f_2 , f_3 , and f_5 . You can use the `add_faults` option `-no_equivalent_clocks` to prevent the addition of faults in equivalent clock domains. In this case, the command does not add faults f_3 and f_5 .

add_gate_to_rtl_mapping

Context: all contexts

Mode: setup

Adds rules for post-synthesis/post-layout to RTL instance name-mapping for DEF files.

Usage

```
add_gate_to_rtl_mapping -instance_name_map_list string_pair_list
```

Description

This command enables you to add extra name-mapping rules for post-synthesis/post-layout to RTL name mapping for DEF file instances. Normally, the [read_def](#) command is capable of handling the mapping of all instances from the DEF file to those in the RTL design without any user intervention. The `add_gate_to_rtl_mapping`, [report_gate_to_rtl_mapping](#), and [delete_gate_to_rtl_mapping](#) commands can be used to create and manage additional mapping rules as needed in cases where the `read_def` command failed to map gate-level DEF file instances.

Arguments

- **-instance_name_map_list *string_pair_list***

A required switch and string pair list that specifies the instance name mapping rules to be added. The *string_pair_list* must contain an even number of string entries, where the first string of the pair is the gate instance name in the DEF file and the second string is the RTL instance name in the design.

Examples

The DEF file `A.def` lists the following memory instances that did not map to RTL instances during the `read_def` command execution:

```
A/B[0].pool/mem1
A/B{0}.pool/mem2
A/B[1].pool/mem3
A/B[1].pool/mem4
```

These DEF instances correspond to the following RTL instances in the design:

```
A/\B[0].pool/mem1
A/\B[0].pool/mem2
A/\B[1].pool/mem3
A/\B[1].pool/mem4
```

The following `add_gate_to_rtl_mapping` command can be used to map the DEF instances to the RTL instances in the design:

```
add_gate_to_rtl_mapping -instance_name_map_list {
    {B[0].pool} {\B[0].pool}
    {B[1].pool} {\B[1].pool} }
```

add_icl_ports

Context: patterns -ijtag, dft

Mode: setup, insertion

Specifies top design ports that are added in the ICL file generated during ICL extraction.

Usage

```
add_icl_ports port_objects [-type ijtag_function] [-function_modifier modifier]
  [-source source_port_object [-inverted] | -trace] [-forced_low_dft_signal_list
  forced_low_dft_signals] [-forced_high_dft_signal_list forced_high_dft_signals]
```

Description

Specifies top design ports that are added in the ICL file generated during ICL extraction. The ports can be of any ICL port type listed in the [ICL Port Types](#) table below.

Table 3-14. ICL Port Types

ICL Port Type	IJTAG Function	Direction
DataInPort	data_in	Input
DataOutPort	data_out	Output
ScanInPort	scan_in	Input
ScanOutPort	scan_out	Output
ClockPort	clock	Input
ToClockPort	to_clock	Output
ResetPort, ActivePolarity 1	reset	Input
ToResetPort, ActivePolarity 1	to_reset	Output
ResetPort, ActivePolarity 0	reset_n	Input
ToResetPort, ActivePolarity 0	to_reset_n	Output
TCKPort	tck	Input
ToTCKPort	to_tck	Output
TMSPort	tms	Input
ToTMSPort	to_tms	Output
TRSTPort	trst	Input
ToTRSTPort	to_trst	Output
CaptureEnPort	capture_en	Input

Table 3-14. ICL Port Types (cont.)

ICL Port Type	IJTAG Function	Direction
ToCaptureEnPort	to_capture_en	Output
ShiftEnPort	shift_en	Input
ToShiftEnPort	to_shift_en	Output
UpdateEnPort	update_en	Input
ToUpdateEnPort	to_update_en	Output
SelectPort	select	Input
ToSelectPort	to_select	Output
AddressPort	address	Input
WriteEnPort	write_en	Input
ReadEnPort	read_en	Input
IRSelectPort	ir_select	Input
ToIRSelectPort	to_ir_select	Output

You must specify the current design with the [set_current_design](#) command before issuing this command. Changing the current design discards all previously specified input and output ICL ports. The tool validates that the ports specified as input ports are input or bidirectional ports, and ports specified as output ports are bidirectional or output ports.

Note

 You must load the design (gate-level Verilog or RTL) before you issue the [set_current_design](#) command as the tool verifies that the specified ports exist in the portlist. You may also load the top-level design as a black-box module.

During ICL extraction, top level ports in the controlling fanin of input ports of sub-modules are automatically inferred as input ports, and top level ports in the controlling fanout of output ports of sub-modules are automatically inferred as output ports. Use this command if you want the top level ICL file to declare input or output ports even when they do not have any input or output ports in their fanin or fanout. Later on, when the current design is integrated into a higher module, ICL extraction traces the newly created input and output ports and ijtag retargeting can be used to retarget [iWrite](#) and [iRead](#) commands to the boundary of the new top module.

The IJTAG function “to_clock” plays a special role. Ports of the current design with this IJTAG function serve as starting points for ICL Extraction tracing, and the tool enforces proper connectivity of those ports. If there is no appropriate driver for the newly created ToClockPort of the top module (ToClockPort of another ICL instance, ClockPort of the top module, internal clock), an I2 violation is reported.

Arguments

- ***port_objects***

A required string that specifies a Tcl list of one or more design port names or a collection of one or more design ports. An error is generated if the specified ports are not found in the portlist of the design.

The ports in the collection must not have been used as arguments of the `-source` switch of another `add_icl_port` command before. (A port that is already in use as a “source port”, cannot be modified by means of `add_icl_ports`.)

- `-type ijtag_function`

An optional switch and literal pair that specifies the function that the ports have in the generated ICL module. The currently supported IJTAG functions are listed in the [ICL Port Types](#) table. If the `-type` option is not specified, the ICL port type is inferred as `DataInPort` for input ports and `DataOutPort` for output ports. In case of bidirectional ports, the ICL port type is inferred as `DataInPort`, if the `-source` option is omitted, and as `DataOutPort`, if the `-source` option is specified. An error is generated if the specified type conflicts with the actual port direction.

- `-function_modifier modifier`

An optional switch and literal pair that specifies the function modifier that the ports have in the generated ICL module. See the [function_modifier icl_port](#) attribute for more information.

- `-source source_port_object`

An optional switch and value pair that specifies the top level port that is used as source of the **port_objects** in the ICL file generated during ICL Extraction. This switch can be used to enforce feedthroughs (direct connections between a primary input port and a primary output port), which otherwise would not be created by ICL Extraction, because ICL Extraction does not start tracing at the top level ports.

The port specified as *source_port_object* must have been added as an ICL port by means of the `add_icl_ports` command before.

- `-inverted`

An optional switch that specifies that the connections between the *source_port_object* and the **port_objects** shall be inverting.

- `-trace`

An optional switch that specifies that ICL Extraction should trace from the specified primary input port or primary output port. It is mutually exclusive with the `-source` switch. This switch can be used to trigger the extraction of connections that would otherwise not be found, for example because of the usage of “`set_icl_extraction_options -ignore_muxes_at_data_out_ports on`” in combination with `DataOutPorts` that fan out to primary outputs.

add_icl_ports

- `-forced_low_dft_signal_list forced_low_dft_signals`
An optional switch that triggers the creation of the associated attribute on the ICL port in the extracted ICL. The parameter `forced_low_dft_signals` specifies a list of signal names to assert low during tracing from this port.
- `-forced_high_dft_signal_list forced_high_dft_signals`
An optional switch that triggers the creation of the associated attribute on the ICL port in the extracted ICL. The parameter `forced_high_dft_signals` specifies a list of signal names to assert low during tracing from this port.

Examples**Example 1**

The following example declares an ICL DataInPort port D1, and three ICL DataOutPort ports O1 O2 and O3. The generated ICL module includes “DataInPort D1;”, “DataOutPort O1;”, “DataOutPort O2;” and “DataOutPort O3;” even if no ICL ports traced to or from them in the design.

```
set_current_design top
add_icl_ports D1 -type data_in
add_icl_ports {O1 O2 O3} -type data_out
```

Example 2

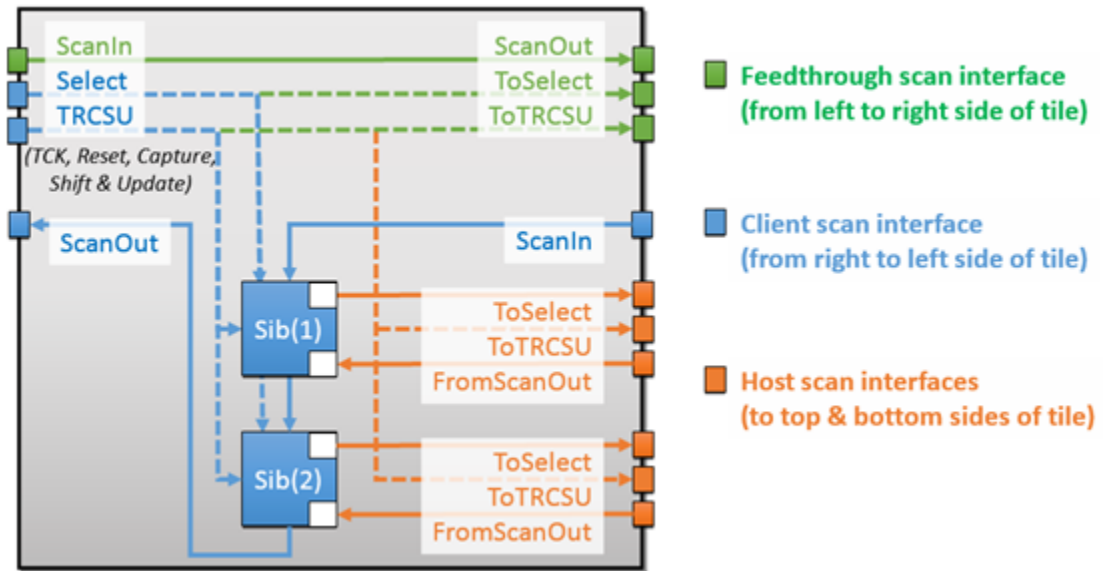

The following example declares two ICL host ScanInterfaces and an ICL client ScanInterface and enforces the control ports of the host ScanInterfaces to be driven directly by the control ports of the client ScanInterface. Parts of the SelectPorts, ToSelectPorts, ScanInPorts and ScanOutPorts are assumed to be created and connected automatically.

```
add_icl_scan_interfaces {host1 host2 client}
set_icl_scan_interface_ports -name host1 -ports {toCe1 toSe1 toUe1 toSel1 fromSo1 toSi1}
set_icl_scan_interface_ports -name host2 -ports {toCe2 toSe2 toUe2 toSel2 fromSo2 toSi2}
set_icl_scan_interface_ports -name client -ports {ce se ue sel si so}
add_icl_ports ce -type capture_en
add_icl_ports se -type shift_en
add_icl_ports ue -type update_en
add_icl_ports si -type scan_in
add_icl_ports {toCe1 toCe2} -type to_capture_en -source ce
add_icl_ports {toSe1 toSe2} -type to_shift_en -source se
add_icl_ports {toUe1 toUe2} -type to_update_en -source ue
add_icl_ports {toSi1 toSi2} -type scan_out -source si
```

Example 3

This example adds two SIBs inside a block and connects them into a ring between the si/so of the client interface. This same concept can be generalized to a greater number of scan interfaces if required. Two host ports are then created below each SIB to open up the path to for tiling rows.

add_icl_scan_interfaces

Context: patterns -ijtag, dft

Mode: setup, insertion (dft context only)

Adds the specified scan interfaces to the new ICL top module that is created during ICL extraction.

Usage

add_icl_scan_interfaces *name_list* [-chains *chain_name_list*]

Description

You only need to use this command if the top module on which ICL extract is running has more than one ScanInterface. In most cases, even when the top module has more than one ScanInterface, ICL extract is able to infer them correctly from the connections to and from the lower-level ICL modules. Only in complicated cases, the heuristic used by ICL extraction may fail; in this case, you use this command to describe the ScanInterface of the top module and they are reflected in the generated ICL of the top module.

Every ScanInterface must have a port list, so after using the add_icl_scan_interfaces command, use the set_icl_scan_interface_ports command to set the list of ports for each ScanInterface.

You must set the current design with set_current_design before using the add_icl_scan_interfaces command.

Arguments

- *name_list*
A required list that specifies the names of scan interfaces that ICL extraction creates in the new ICL top module.
- -chains *chain_name_list*
An optional switch and value pair that specifies the list of scan chain names used to create client scan interfaces with multiple chains. If you specify this argument, the scan interfaces are created with the specified scan chains.

Note

 Every ScanInterface must have a port list. After using the add_icl_scan_interfaces command, use the set_icl_scan_interface_ports command to set the list of ports for each ScanInterface. If the -chains argument is used, the set_icl_scan_interface_ports command must be called multiple times: once to specify the common ports of the scan interface, and once for each of the scan chains to specify their scan_in and scan_out port.

Examples

Example 1

In the following example, the `add_icl_scan_interfaces` command creates ScanInterfaces named TAP and Internal in the new ICL top module during ICL extraction. The `set_icl_scan_interface_ports` command adds the names of the ports to the TAP and Internal ScanInterfaces.

```
set_current_design tap1  
add_icl_scan_interfaces {TAP Internal}  
set_icl_scan_interface_ports -name TAP -ports {tck tdi tdo tms trst}  
set_icl_scan_interface_ports -name Internal -ports {tdo tdrEn1 fromTdr1 ce se ue}
```

The resulting ICL model would look like this:

```
Module tap1 {  
  
    TCKPort          tck;  
    ScanInPort       tdi;  
    ScanOutPort      tdo      { Source IRMux; }  
    TMSPort          tms;  
    TRSTPort         trst;  
    ToSelectPort     tdrEn1   { Source sell; }  
    ScanInPort       fromTdr1;  
    ToCaptureEnPort ce;  
    ToShiftEnPort    se;  
    ToUpdateEnPort   ue;  
  
    ScanInterface TAP {Port tck; Port tdi; Port tdo; Port tms; Port trst;}  
    ScanInterface Internal {Port tdo; Port tdrEn1; Port fromTdr1; Port ce;  
                           Port se; Port ue;}  
}
```

Example 2

In the following example, the `add_icl_scan_interfaces` command is used to create a client scan interface with two scan chains.

```
set_current_design top  
add_icl_scan_interfaces { intf_1 } -chains { chain_1 chain_2 }  
set_icl_scan_interface_ports -name intf_1 -ports { ce se ue }  
set_icl_scan_interface_ports -name intf_1 -ports { si_1 so_1 } -chain chain_1  
set_icl_scan_interface_ports -name intf_1 -ports { si_2 so_2 } -chain chain_2
```

The resulting ICL model looks like this:

```
Module top{
  ScanInPort si_1;
  ScanInPort si_2;
  ScanOutPort so_1 {
    Source i1.so;
  }
  ScanOutPort so_2 {
    Source i2.so;
  }
  CaptureEnPort ce;
  ShiftEnPort se;
  UpdateEnPort ue;
  ScanInterface intf_1 { Port ce; Port se; Port ue;
    Chain chain_1 { Port si_1; Port so_1; }
    Chain chain_2 { Port si_2; Port so_2; }
  }
}
```

add_icl_ssn_datapaths

Context: all contexts

Mode: setup, insertion

Specifies the SSN datapath identifiers that Tessent Shell will associate with certain ICL ports of the new ICL top module during ICL Extraction.

Usage

add_icl_ssn_datapaths *name_list*

Description

The bus data ports and the clock ports of a SSN datapath must be associated with this datapath by means of the icl_port attribute tessent_ssn_datapath_ids. The position of a bus data port within the bus must be described by means of the icl_port attribute tessent_ssn_datapath_bus_index.

When the top module ICL is elaborated, Tessent Shell analyzes the existing SSN datapaths and attaches the attributes to the ports, if possible and unambiguous. Usually, Tessent Shell is capable of deducing the attribute values from the topology of the SSN datapaths and from the existing SSN datapath attributes deeper down the ICL hierarchy. However, sometimes the association between the ICL top module ports and the SSN datapaths is ambiguous, for example, if there are extra output paths. In this case, the commands add_icl_ssn_datapaths and [set_icl_ssn_datapath_ports](#) must be used to instruct the tool during ICL extraction to attach the appropriate attributes to the ICL ports of the newly-created ICL top module.

The command add_icl_ssn_datapaths introduces new SSN datapath identifiers. Only SSN datapath names that have been registered by means of add_icl_ssn_datapaths can later be used in the set_icl_ssn_datapath_ports command.

Arguments

- *name_list*

A Tcl list of names that are registered as SSN datapath identifiers and that will later be used as values in the icl_port attribute tessent_ssn_datapath_ids. Names can contain only numbers, letters, and underscores. Including other characters in names in the list causes the tool to report an error.

Examples

```
SETUP> add_icl_ssn_datapaths {A B}
SETUP> set_icl_ssn_datapath_ports -name A -clock_inputs bus_clock \
    -bus_data_inputs bus_a_in[11:0] -bus_data_outputs bus_a_out[11:0]
SETUP> set_icl_ssn_datapath_ports -name B -clock_inputs bus_clock \
    -bus_data_inputs bus_b_in[23:0] -bus_data_outputs bus_b_out[23:0]
SETUP> extract_icl
```

add_iddq_exceptions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables you to specify individual sites where the tool does not apply the Iddq restrictions.

Usage

add_iddq_exceptions *ZVAL_gate...*

Description

You can achieve maximum quiescence by using the appropriate IDDQ checks, and adding exceptions for as few sites as possible while still obtaining patterns that are not rejected for violation of IDDQ checks during fault simulation.

For more information on IDDQ, refer to “[IDDQ Test Set Creation](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- *ZVAL_gate...*

A required repeatable string that declares the gate name or gate identification number of a site for which the tool could report Iddq check violations. (See the [set_iddq_checks](#) command for specifics about setting Iddq checks). These sites are always roots of tri-state buses (ZVAL gates at the primitive level).

Note

 If a site does not have a unique name, you must provide a gate identification number.

The “`report_gates -type zval`” command gives a list of all candidates, but typically you only need to use the gate identification numbers reported by the [analyze_restrictions](#) command.

Examples

The following example adds Iddq restrictions, uses the `analyze_restrictions` command to locate the sources of violations, then adds an Iddq exception to remove one of them.

```
set_iddq_checks -int_float
simulate_patterns
analyze_restrictions

...
// Will attempt to locate and report specific -int_float violators.
// No single bus is constrained to Z (or already Z). Will analyze
// further.
// The following ZVAL gates cause -int_float to fail by themselves.
//   ZVAL gate /cpu/alu/U2392/ (54417).  ABORTed.
//   ZVAL gate /cpu/alu/U4177/ (63712).  ABORTed.
...
```

add_iddq_exceptions /cpu/alu/U2392/

To use the analyze_restrictions command most effectively, you must have design knowledge; in some cases, design knowledge is required in order to pinpoint the source of the violation.

add_ijtag_logical_connection

Context: patterns -ijtag

Mode: setup

Creates a new logical connection path through the current design by specifying the source and destination of the logical path.

Usage

```
add_ijtag_logical_connection -from source_pin_or_port_name  
    [-from_pin_direction {input | output}]  
    -to destination_pin_or_port_name  
    [-to_pin_direction {input | output}]  
    [-inverted]
```

Description

During ICL connection tracing, logical connections are followed in preference to the actual connections. When tracing reaches an instance pin with a logical connection, it follows the logical connection across the design hierarchy. A forward trace only follows logical connections that start on the pin being traced and then skip to the destination of the logical connection. A backward trace only follows logical connections that have a destination on the pin being traced and then skip to the source of the logical connection.

See “[Example 1](#)” on page 288 for an example of a logical connection.

Use this command with care as it basically bypasses the structural tracing of the circuit and uses an act of faith on the behavior of the specified logical source. If the behavior turns out to be inconsistent with the specified logical sources, you only detect the issue in simulation. Use this command to model logical sources through blackbox modules or to model a path where the logic is too complex. A circuit that gates TCK with capture and shift enable provides proper capture and shift behavior but would not be properly traceable by ICL extraction. In such a case, using a logical source to enable tracing through the tck gating logic is needed.

The following attributes are used to store the source...destination relationship for the two ends of the logical connection:

Table 3-15. Logical Connection Attributes

Attribute Name	Usage
ijtag_logical_hier_connection_from_src	<p>Associated with the top-level module port or instance pin that is the destination of a hierarchical logical connection.</p> <p>A string list of top level module port names and hierarchical instance pin path names to the source ends of these logical connections.</p> <p>This attribute is not inherited but does cause the hierarchical boundary to be preserved.</p>
ijtag_logical_hier_connection_from_src_inv	<p>Associated with the top-level module port or instance pin that is the destination of a hierarchical logical connection.</p> <p>A string list of top level module port names and hierarchical instance pin path names to the source ends of these logical connections.</p> <p>This attribute is not inherited but does cause the hierarchical boundary to be preserved.</p>
ijtag_logical_hier_connection_to_dst	<p>Associated with the top-level module port or instance pin that is the source of a hierarchical logical connection.</p> <p>A string list of top level module port names and hierarchical instance pin path names to the destination ends of these logical connections.</p> <p>This attribute is not inherited but does cause the hierarchical boundary to be preserved.</p>

Table 3-15. Logical Connection Attributes (cont.)

Attribute Name	Usage
ijtag_logical_hier_connection_to_dst_inv	<p>Associated with the top-level module port or instance pin that is the source of a hierarchical logical connection.</p> <p>A string list of top level module port names and hierarchical instance pin path names to the destination ends of these logical connections.</p> <p>This attribute is not inherited but does cause the hierarchical boundary to be preserved.</p>

The following figure illustrates the usage of these attributes.

Figure 3-21. Logical Connection Attributes

These attributes are available for direct read only introspection by the user, like the other predefined ICL extraction attributes. They are all cleared when the `set_current_design` command is run.

Arguments

- **-from *source_pin_or_port_name***
A required switch and value pair that specifies the source point of the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.
- **-from_pin_direction {input | output}**
An optional switch-value pair that enables you to specify the pin direction of the source of the `ijtag_logical_connection`, if the pin specified by the “-from” switch is a bidirectional pin.
- **-to *destination_pin_or_port_name***
A required switch and value pair that specifies the destination point of the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.
- **-to_pin_direction {input | output }**
An optional switch-value pair that enables you to specify the pin direction of the destination of the `ijtag_logical_connection`, if the pin specified by the “-to” switch is a bidirectional pin.
- **-inverted**
An optional switch that specifies that the logical connection is inverted.

Examples

Example 1

The following example illustrates a logical connection from pin U1/Y to pin U2/A. A forward trace that arrives at pin U1/Y continues on from pin U2/A. A backward trace that arrives at pin U2/A continues on from pin U1/Y.

Figure 3-22. Logical Connection Example

At the netlist level all interconnections start at an instance pin or a top level module port and end at an instance pin or top level module port. Establishing a logical connection within the design hierarchy does not alter the way that design hierarchy is traversed by ICL extraction tracing when that design hierarchy is used as part of a larger design hierarchy, from a different top-level module.

Example 2

The `add_ijtag_logical_connections` command creates logical connections between the pins `/i2/in` and `/i2/out`, `/i3/in` and `/i3/out` and `i4/in` and `/i4/out`, and an inverted logical connection between `/i5/in` and `/i5/out`. The `report_ijtag_logical_connections` command reports all logical connections in the current design.

```
add_ijtag_logical_connection -from /i2/in -to /i2/out  
add_ijtag_logical_connection -from /i3/in -to /i3/out  
add_ijtag_logical_connection -from /i4/in -to /i4/out  
add_ijtag_logical_connection -from /i5/in -to /i5/out -inverted  
report_ijtag_logical_connections  
  
// IJTAG Logical Connections:  
// From Source To Destination Inversion  
// =====  
// /i2/in /i2/out no  
// /i3/in /i3/out no  
// /i4/in /i4/out no  
// /i5/in /i5/out yes
```

add_input_constraints

Context: all contexts

Mode: setup, analysis (dft -edt and patterns -scan contexts only)

Constrains primary inputs to specified values.

Usage

Context: dft -scan and dft -test_points

```
add_input_constraints
  {{{[-AL] | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs]
   constraint_switch} |
  {[-Equivalent reference_pin [equivalent_pin]... [-INvert inverted_pin...]]
   [constraint_switch]}}
```

Context: patterns -scan

```
add_input_constraints
  {{{[-AL] | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs]
   constraint_switch} |
  {[-Equivalent reference_pin [equivalent_pin]... [-INvert inverted_pin...]]
   [constraint_switch]}}
  [-HOLD] [-NO_Z] [-SLOW_pad [-CELL model_name]]
```

Context: patterns -ijtag

```
add_input_constraints
  {{{[-AL] | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude]
   constraint_switch} |
  {[-Equivalent reference_pin [equivalent_pin]... [-INvert inverted_pin...]]
   [constraint_switch]}}
```

Description

The add_input_constraints command constrains primary input pins to specified values.

Note

 Do not force a constrained pin to a new value in any cycle of a named capture procedure (NCP), even temporarily. To ensure state stability, a constrained pin's state must be kept constant for all cycles of NCPs.

In the patterns -ijtag context, you can constrain all Verilog ports unless the port is also an ICL port. Input constraints on ICL ports are enabled only for ICL ports of type DataInPorts, TRSTPort, and ClockPort. For more information, see “[How to Constrain Inputs](#)” in the *Tessent IJTAG User's Manual*.

Inferred input constraints

Some input constraints are automatically applied to certain input ports of the current design, depending on the current context and the ICL port function. There are also attributes that trigger the creation of input constraints.

Constraints derived from ICL port functions

If there is an ICL description for the current design, then the following constraints are applied during the processing of the command `set_current_design` in all contexts except “patterns -ijtag”: A port with ICL port function TMSPort is constrained to C0. A port with ICL port function TRSTPort is constrained to C1 unless there is already a CT1 constraint for that port. Ports with ICL port function ResetPort are constrained to their inactive values, using the constraint types “C0” or “C1”. All ports with ICL port functions CaptureEnPort, ShiftEnPort and UpdateEnPort are constrained to C0, unless the associated ICL ScanInterfaces contain ports with ICL port function SelectPort, in which case only the SelectPorts are constrained to C0. When the context is set to “patterns -ijtag”, the constraints are automatically removed. They are reapplied if the context is set to any other context but “patterns -ijtag”.

Constraints derived from ICL module attributes

If the ICL module, which is associated with the current design, contains the “forced_low_input_port_list” or “forced_high_input_port_list” `icl_module` attributes, then the ports referenced by those attributes are constrained appropriately, using the constraint types “C0” and “C1”. The constraints are applied during the processing of the command “set_current_design”.

Constraints derived from port attributes

Ports with the `Port` attribute “function” set to “power” or “ground” are constrained appropriately, using the constraint types “CT1” and “CT0”. The constraints are applied during the processing of the command “set_current_design”.

Constraints on ports with ICL port function DataInPort

At the end of a test_setup procedure that contains iCall or iMerge statements, all ports with ICL port function DataInPort are constrained to C0 or C1, according to the last values that have been assigned to them during the IJTAG retargeting of the iCall and iMerge commands. This behavior is suppressed, if the port has the `icl_module` attribute “tessent_no_input_constraints” set to “on”.

Arguments

- `-ALL`
An optional switch that applies the constraint to all applicable primary input pins except clocks, read controls, and write controls. If `-Slow_pad` is also specified, the constraint is only applied to primary input pins that can take a Z value. This is the default.
- `primary_input_pin_name`
An optional, repeatable string that specifies the name of a primary input pin to which to apply the constraint.

- **-BIDI_Only**
An optional switch that specifies to apply the constraint to bidirectional pins only.
- **-BIDI_Exclude**
An optional switch that specifies to apply the constraint only to primary input pins that are not bidirectional.
- **-SCAN_Inputs**
An optional switch that specifies to apply the constraint to scan input pins only.
- **-Equivalent *reference_pin* [*equivalent_pin*]...**
An optional switch, string, and repeatable string triplet that specifies for the *primary_input_pin_name*(s) to take on the value of the *reference_pin*. If you optionally specify one or more of the *primary_input_pin_name*(s) as *equivalent_pin*(s), those PIs in the *equivalent_pin* list take on the value of the *reference_pin*. You must list pins you want to be equivalent in value to the reference pin before the **-Invert** argument when used.
- **-INvert *inverted_pin*...**
An optional switch and repeatable string that together with the **-Equivalent** switch specify for the primary input pins, *inverted_pin*, to take on the inverted value of the *reference_pin*. You must list the pins you want to be inverted in value after the **-Invert** argument.
- ***constraint_switch***
A required switch that specifies the constant value to which to constrain the primary input pin(s). This switch is required unless you specify the **-Equivalent** switch.

The choices, from which you can specify only one, are as follows:

-C0 — Specifies application of the constant 0 to the chosen primary input pin.

The tools do not use constant 0 constraints to determine tied circuitry. Therefore, faults associated with line holds resulting from these constraints are classified as **ATPG_untestable (AU)**, as opposed to **Tied (TI)** or **Blocked (BL)**. Use a **-C0** constraint if the constraint is valid in test mode, but not valid in system mode.

Note

 If the constraint is valid in system mode as well, consider using **-CT0** instead. Faults associated with tied circuitry resulting from a **-CT0** constraint are not classified as **ATPG_untestable**, thereby improving test coverage compared to using a **-C0** constraint. To ensure the improvement in coverage matches reality, however, be sure to use **-CT0** only for valid system mode constraints.

-C1 — Specifies application of the constant 1 to the chosen primary input pin.

The tools do not use constant 1 constraints to determine tied circuitry. Therefore, faults associated with line holds resulting from these constraints are classified as **ATPG_untestable (AU)**, as opposed to **Tied (TI)** or **Blocked (BL)**. Use **-C1** if the constraint is valid in test mode, but not valid in system mode.

Note

 If the constraint is valid in system mode as well, consider using -CT1 instead. Faults associated with tied circuitry resulting from a -CT1 constraint are not classified as ATPG_untestable, thereby improving test coverage compared to using a -C1 constraint. To ensure the improvement in coverage matches reality, however, be sure to use -CT1 only for valid system mode constraints.

-CX — Specifies application of the constant X (unknown) to the chosen primary input pin. The tools do not use the specified primary input pin for control.

-CZ — Specifies application of the constant Z (high-impedance) to the chosen primary input pin. The CZ constraint is only applicable to bidi pin and PI that fans out only to Z consumer gates, such as PO, or bus. For a PI that fans out to non Z consumer gate, when CZ is added the tool reports a warning message during the flattening process and convert CZ constraint into CX constraint automatically. For example:

```
// Warning: Invalid constant Z pin constraint on pin te5 changed to  
// constant X.
```

-CT0 — Specifies application of the constant TIE0. The ATPG process treats this constraint as if you had added a tied signal.

The tools classify faults associated with tied circuitry resulting from a -CT0 pin constraint as untestable (Tied (TI) or Blocked (BL)). These faults are not included in the calculation of test coverage, so they neither raise nor lower coverage. If instead, the faults were associated with a -C0 pin constraint, the tool would classify them as ATPG_untestable (AU) and they would reduce coverage. Therefore, it is advantageous to use a -CT0 instead of a -C0 constraint; but take care that any -CT0 constraint you apply for test is valid in system mode—to ensure the relative boost in coverage is real.

Note

 You cannot override a -CT0 value (from a test procedure file for example). If you need this flexibility, use -C0 instead.

-CT1 — Specifies application of the constant TIE1. The ATPG process treats this constraint as if you had added a tied signal.

The tools classify faults associated with tied circuitry resulting from a -CT1 pin constraint as untestable (Tied (TI) or Blocked (BL)). These faults are not included in the calculation of test coverage, so they neither raise nor lower coverage. If instead, the faults were associated with a -C1 pin constraint, the tool would classify them as ATPG_untestable (AU) and they would reduce coverage. Therefore, it is advantageous to use a -CT1 instead of a -C1 constraint; but take care that any -CT1 constraint you apply for test is valid in system mode—to ensure the relative boost in coverage is real.

Note

 You cannot override a -CT1 value (from a test procedure file for example). If you need this flexibility, use -C1 instead.

-CTZ — Specifies application of the constant TIEZ. The ATPG process treats this constraint as if you had added a tied signal.

The tools classify faults associated with tied circuitry resulting from a -CTZ pin constraint as untestable (Tied (TI) or Blocked (BL)). These faults are not included in the calculation of test coverage, so they neither raise nor lower coverage. If instead, the faults were associated with a -CZ pin constraint, the tool would classify them as ATPG_untestable (AU) and they would reduce coverage. Therefore, it is advantageous to use a -CTZ instead of a -CZ constraint; but take care that any -CTZ constraint you apply for test is valid in system mode—to ensure the relative boost in coverage is real.

- **-HOLD**

An optional switch that, for clock sequential patterns only, holds the constant constraint value at the primary input(s) for all cycles of a clock_sequential or multiple_load pattern. Even if a pattern has multiple loads, the primary input's value cannot change among different load intervals. The hold does not apply to clocks, read controls and write controls. It also does not apply to launch off shift patterns, RAM sequential patterns, or patterns with a clock procedure.

If the fault type is set to transition and you enter a “set_transition_holdpi On” command, the constraint defined by the add_input_constraints command is overridden by the set_transition_holdpi command; that is, all primary inputs except clocks and read/write controls are going to hold their values even if you have not applied a constraint to a particular primary input. Similar behavior occurs when the fault type is set to path delay and you enter a “set_pathdelay_holdpi On” command.

- **-NO_Z**

An optional switch that specifies not to permit a Z value at the specified primary input pin(s) during test generation, even if the pins can support a Z value. During good machine simulation, a pattern is rejected if it assigns a Z value to any primary input that is specified to have no Z value. This switch is invalid with either the -CZ or -CTZ switch.

- **-Slow_pad**

An optional switch that specifies to X out the value at a bidirectional pin if the pin is driven from within during test generation.

-CELL *model_name*

An optional switch and string pair that together with the -Slow_pad switch specifies the scope of the bidirectional pins to be included as slow pads. Only the bidirectional pins that drive the instances initiated from the specified library cell name are added as slow pads.

Examples

Example 1

The following example shows two differential clocks, CLK1 off state 0 and CLK2 off state 1. Because the pins are equivalent, you only need to add the clock to one of the pins. The

command order is important: *you must* first define equivalent pins, then define one of them as the clock, otherwise the tool reports an error. The tool infers CLK2 to be a clock.

```
add_input_constraints -equivalent CLK1 -invert CLK2
add_clocks 0 CLK1
// Note: Equivalent pin CLK2 also added to clock list.
```

Example 2

The following example shows how to add equivalent clocks that are inverted.

```
SETUP> add_clocks 0 mode[1] -pulse_always
SETUP> add_clocks 1 mode[2] -pulse_always
SETUP> report_clocks
User-defined Clocks (2):
=====

Sync and Async Source Clocks
=====
-----
Name      Off State  Constraints  Internal
-----
mode[2]   1          Pulse always  No
mode[1]   0          Pulse always  No

SETUP> add_input_constraints -equivalent mode[1] -inv mode[2]
SETUP> report_input_constraints
// Primary Input  Equivalent  C-Type  Hold  No-Z  Slow-Pad
// -----
// mode[1]                NONE    No    Undetermined    No
//                ~mode[2]  NONE    No    Undetermined    No
```

Example 3

This example specifies multiple equivalent pins: clk, clk1, and clk2. Pin clk1 is equivalent to the reference pin, clk. Pin clk2 is inverted from the reference pin, clk.

```
SETUP> add_input_constraints -equivalent clk clk1 -invert clk2
SETUP> add_clocks 0 clk
// Note: Equivalent pin clk1 and clk2 are also added to clock list.

SETUP> report_clocks
```

User-defined Clocks (3):

add_layout_core_information

Context: patterns -scan_diagnosis

Mode: analysis

In hierarchical layout-aware diagnosis, adds core instance information to an existing core-level LDB.

Usage

```
add_layout_core_information {-def list_of_DEF_files | -deflist tcl_list |  
    {-design top_design_name -die_area {die_area} -instance instance -placement {x y}  
    -orientation orientation} }
```

Description

In hierarchical layout-aware diagnosis, adds core instance information to an existing core-level LDB. This information can come from three sources, which are mutually exclusive: a space-separated list of top-level DEF files, a Tcl list of top-level DEF files, or the actual core instance data chip-mapped to the top level.

To use this command you must have a valid LDB that you previously opened using the `open_layout` command. Normally, you also have top-level DEF files that instantiate the core represented by the currently opened LDB, and the DEF file for the core represented by the currently opened LDB. If you only have core-level DEF files, you can manually add chip-mapped core instance information.

When run, the command extracts the instance information for the core represented by the LDB from the top-level DEF file(s) and stores this information in the LDB. This makes the LDB instance-aware, which is a requirement for hierarchical layout-aware diagnosis.

This command enables you to store core instance information from multiple SoC designs in the same LDB, which is helpful when the same core is used in multiple designs.

See “[Diagnosis for Hierarchical Design](#)” in the *Tessent Diagnosis User's Manual* for more information.

Arguments

- **-def** *list_of_DEF_files*
A switch and string pair that specifies a space-separated list of top-level DEF files that contain placement and orientation information for each core.
- **-deflist** *tcl_list*
A switch and string pair that specifies a Tcl list of top-level DEF files that contain placement and orientation information for each core.

- `-design design_name -die_area {die_area} -instance instance -placement {x y} -orientation orientation`

A series of switches that must be specified together. Use these switches to manually add the instance information for a core to an existing LDB. You must specify separate `add_layout_core_information` commands for each core you want to manually add.

`-design top_design_name`: The name of the top module of the design.

`-die_area {die_area}`: Four integers that specify the X,Y coordinates of the core with origin at 0,0. The first and second integers specify the bottom-left corner of the core, and the third and fourth integers specify the top-right corner of the core.

`-instance instance`: The core instance name.

`-placement {x y}`: Integers that represent the x, y placement of the specified core in the top-level DEF, where x and y indicate the bottom right corner of the core.

`-orientation orientation`: A string that specifies the orientation of the core instance, where the possible choices are: { N | W | S | E | FN | FW | FS | FE }.

Examples

The following example adds two core instances of coreA to an existing LDB.

```
add_layout_core_information top_chip -die_area {-4000 -4000 20000000 40000000} \  
-instance cpu_coreA -placement {2000 2000} -orientation N
```

```
add_layout_core_information top_chip -die_area {-2000 -2000 10000000 20000000} \  
-instance cpu_coreA -placement {50 100} -orientation FS
```

[report_layout_core_information](#)

add_lfsr_connections

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Connects an external pin or an internal pin to a Linear Feedback Shift Register (LFSR).

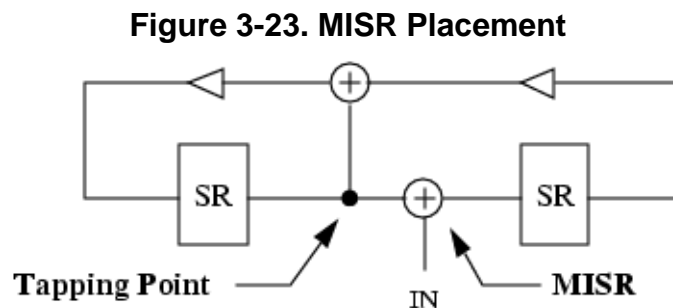

Usage

add_lfsr_connections *pin_pathname lfsr_name position...*

Description

The `add_lfsr_connections` command connects a core logic pin to an LFSR. You specify this pin with the `pin_pathname` argument. LFSR bit positions have integer numbers, where 0 indicates the least significant bit position. The tool assumes that the output of the 0 bit position connects to the input of the highest bit position. If you select multiple bits of a Pseudo-Random Pattern Generator (PRPG) for the `position` argument, the tool assumes they are all exclusive-ORed together to create the value for the pin.

If you determine that multiple pin names must connect to a bit position of a Multiple Input Signature Register (MISR), you must issue a separate `add_lfsr_connections` command for each pin. The tool assumes the pins are all exclusive-ORed together to create the value for the next MISR input. The tool also assumes that the physical placement of the MISR connections is after the tapping points as shown in [Figure 3-23](#).

You can use the `report_lfsrs` command to display all the LFSRs with their current values and tap positions.

Arguments

- ***pin_pathname***
A required string that specifies the pin pathname (`<instance pathname>/<pinname>`) of the core logic pin that you want to connect to the LFSR specified by `lfsr_name`.
- ***lfsr_name***
A required string that specifies the name of the LFSR to which you want to connect the `pin_pathname`.

- *position*

A required repeatable integer that specifies the bit positions of the *lfsr_name* at whose outputs you want to place connections. A bit position is an integer number, where 0 indicates the least significant bit position. The tool assumes the output of the 0 bit position connects to the input of the highest bit position.

Examples

The following example connects an LFSR to a scan-in pin and another LFSR to a scan-out pin:

```
add_lfsrs lfsr1 prpg 5 10 -serial -in
add_lfsrs misr1 misr 5 15 -both -out
add_lfsr_taps lfsr1 1 3
add_lfsr_taps misr1 1 2
add_lfsr_connections scan_in.1 lfsr1 2
add_lfsr_connections scan_out.0 misr1 3
```

Related Topics

[add_lfsrs](#)

[add_lfsr_taps](#)

[delete_lfsr_connections](#)

[report_lfsr_connections](#)

add_lfsr_taps

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Adds the tap configuration to a Linear Feedback Shift Register (LFSR) or a PRPG of type cellular automata (CA).

Usage

`add_lfsr_taps lfsr_name position...`

Description

The `add_lfsr_taps` command sets the tap configuration of an LFSR. LFSR bit positions have integer numbers, where 0 indicates the least significant bit position. The tool assumes the output of the 0-bit position connects to the selected tap points and that the 0-bit position cannot itself be a tap point.

If the LFSR is defined as a CA, the tap positions define the position of the self-feedbacks cells (those CA cells defined using rule 150). At least one tap must be defined; otherwise, the consistency check of the PRPG issues an error message.

You can use the `report_lfsrs` command to display all of the LFSRs with their current values and tap positions. You can change the default setting of the `tap_type` switches by using the `set_lfsrs` command.

Arguments

- ***lfsr_name***
A required string that specifies the name of the LFSR on which you want to place the taps.
- ***position***
A required, repeatable integer that specifies the bit positions of the *lfsr_name* at whose outputs you want to place the taps or, for CAs, the bit positions of the self-feedback cells.

Examples

Example 1

The following example places taps on the newly-added LFSRs:

```
add_lfsrs lfsr1 prpg 5 10 -serial -in
add_lfsrs misr1 misr 5 15 -both -out
add_lfsr_taps lfsr1 1 3
add_lfsr_taps misr1 1 2
```

add_lfsr_taps

Example 2

The following example defines a 32-bit PRPG with self-feedback cells at positions 3, 7, 12, 15, 23, 25, and 30:

```
add_lfsrs my_prpg prpg 32 FFFFFFFF -CA  
add_lfsr_taps my_prpg 3 7 12 15 23 25 30
```

[report_lfsrs](#)

[set_lfsrs](#)

add_ifsrs

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Adds LFSRs for use as PRPGs or MISRs.

Usage

```
add_ifsrs lfsr_name {Prpg | Misr} length seed [-Both | -Serial | -Parallel]
          [-Out | -In | -Ca [-INCRement_step value]]
```

Description

The `add_ifsrs` command defines LFSRs, which the tool uses as PRPGs, to create pseudorandom values for the BIST patterns or as MISRs to compact responses.

You specify the LFSR's shift technique by using one of the following `shift_type` switches: `-Both`, `-Serial`, or `-Parallel`. You specify the placement of the exclusive-OR taps by using one of the following `tap_type` switches: `-Out` or `-In`; or you specify the type of LFSR as cellular automata using the `tap_type` switch `-Ca`. You can change the default setting of the `shift_type` and `tap_type` switches by using the [set_ifsrs](#) command.

Arguments

- ***lfsr_name***
A required string that specifies the name that you want to assign to the LFSR. Note that you cannot use the keyword "all" for this name.
- **Prpg**
A literal that indicates the LFSR functions as a PRPG.
- **Misr**
A literal that indicates the LFSR functions as a MISR.
- ***length***
A required integer, greater than 1, that specifies the number of bits in the LFSR.
- ***seed***
A required, right-justified, hexadecimal number, greater than 0, that specifies the initial state of the LFSR.
- **-Both**
An optional switch specifying that the LFSR shifts both serially and in parallel. This is the default unless you change it with the `set_ifsrs` command.
- **-Serial**
An optional switch specifying that the LFSR shifts serially the number of times equal to the length of the longest scan chain for each scan pattern.

- **-Parallel**
An optional switch specifying that the LFSR parallel shifts once for each scan pattern. The following lists the three *tap_type* switches of which you can only choose one.
- **-Out**
An optional switch specifying that the exclusive-OR taps reside outside the register path. This is the default unless you change it with the `set_lfsrs` command.
- **-In**
An optional switch specifying that the exclusive-OR taps reside in the register path.
- **-CA**
An optional switch specifying that the PRPG is of type cellular automata. This switch is only valid if the LFSR type is specified as **Prpg**.
- **-INCrement_step value**
An optional switch that specifies the number of times the PRPG is advanced for each shift cycle. The *value* argument is a required integer.

Examples

Example 1

The following example defines an LFSR to be a PRPG and another LFSR to be a MISR:

```
add_lfsrs lfsr1 prpg 5 10 -serial -in
add_lfsrs misr1 misr 5 15 -both -out
add_lfsr_taps lfsr1 1 3
add_lfsr_taps misr1 1 2
```

Example 2

The following example defines an LFSR to be a PRPG without a phase shifter:

```
add_lfsrs my_prpg prpg 24 FFFFFFF -CA
add_lfsr_taps my_prpg 3 7 12 15 23
add_lfsrs connection scanin_1 my_prpg 0
add_lfsrs connection scanin_2 my_prpg 1
...
add_lfsrs connection scanin_24 my_prpg 23
```

Example 3

The following example defines an LFSR to be a PRPG with a phase shifter:

```
add_lfsrs my_prpg prpg 24 FFFFFFF -CA
add_lfsr_taps my_prpg 3 7 12 15 23
add_lfsr_connections scanin_1 my_prpg 0 3 5
add_lfsr_connections scanin_2 my_prpg 1 7 11
...
add_lfsr_connections scanin_24 my_prpg 9 15 23
```

Example 4

The following example defines an LFSR to be a PRPG and specifies to advance the PRPG eight times for each shift cycle.

```
add_ifsrs my_prpg prpg 24 FFFFFFF -CA -inc 8
add_ifsr_taps my_prpg 3 7 12 15 23
add_ifsrs connection scanin_1 my_prpg 0
add_ifsrs connection scanin_2 my_prpg 1
...
add_ifsrs connection scanin_24 my_prpg 23
```

add_lists

Context: dft -edt, patterns -scan

Mode: analysis

Adds pins to the list of pins on which to report.

Usage

add_lists *pin_pathname*...

Description

The add_lists command enables you to create and add to a list of pins that the tool reports on during simulation.

In “dft -edt” context, you cannot report values on gates in the EDT logic with this command because values inside the EDT logic are not always accurate.

Tip

 This command is a useful debugging aid, as it provides a way to check the values simulated for specific output pins of cells within the design.

To list all the pins on which the tool currently reports during simulation, use the [report_lists](#) command. To turn off reporting of a pin’s simulation values, use the [delete_lists](#) command. To direct the tool to write the pins’ simulation values to a file instead of displaying them on screen, use the [set_list_file](#) command.

When switching to Setup mode, the tool discards all pins from the report list.

Note

 Multiprocessing does not support the add_lists command. If you use this command in distributed mode, the tool deactivates distribution of simulation, which may result in increased run time. When this occurs, or if you use the add_processors command after you have run the add_lists command, the tool reports the following warning:

```
// Warning: The use of the add_lists command prevents the use of
//           distribution and multithreading during simulation, which may
//           have a noticeable effect on performance.
```

Note

 The add_lists command is not supported in the diagnosis context and is automatically deactivated. As a result, the tool does not report any simulation values on pins that were added using the add_lists command.

Arguments

- *pin_pathname*

A required, repeatable string that specifies the output pins on which to report during good or faulty machine simulation.

Examples

The following example writes to the file, *pinlist_goodsim.txt*, the values simulated for two output pins during simulation of an external pattern source:

```
set_system_mode analysis  
read_patterns pattern1  
add_lists /i_1006/o /i_102/o  
set_list_file pinlist_goodsim.txt -replace  
simulate_patterns
```

The following shows the format of the resulting list file: the first column lists the pattern index of each pattern simulated, the second column shows the value simulated on each monitored pin for each pattern. Note that the pattern index refers to the simulated parallel patterns rather than the effective patterns that are stored after ATPG.

```
//          /i_1006/o  
//          | /i_102/o  
//          ||  
//          ||  
//-----  
//      0  11  
//      1  10  
//      2  00  
//      3  10  
//      4  01  
//      5  01  
...  
...
```

Notice that in analysis system mode, the report shows the good value of the pin. The tools also shows the values at each test pattern.

add_lists

The following is example list file content for the same two pins when simulated in analysis system mode:

```
//          /i_1006/o
//          | /i_102/o
//          ||
//          ||
//-----
//          0 11
//          0 0- { /i_1006/o@0 }
//          1 10
//          1 0- { /i_1006/o@0 }
//          2 00
//          2 1- { /i_1006/o@1 }
//          3 10
//          3 0- { /i_1006/o@0 }
//          4 01
//          4 1- { /i_1006/o@1 }
//          5 01
//          5 1- { /i_1006/o@1 }
...

```

The report now includes two lines of information for each pattern simulated. The first line shows the good machine value of each pin as before. The second line shows the faulty value of each pin if different from the good value (a “-” indicates the faulty value was the same as the good value). Inside the “{}” is the fault site and its faulty machine stuck-at value the tool simulated to produce the faulty machine results.

[set_list_file](#)

add_loadboard_loopback_pairs

Context: patterns -ijtag, -scan, -scan_diagnosis, -scan_retargeting

Modes: setup

Prerequisites: Design must be elaborated prior to using this command.

Creates a loopback connection from specified output ports to specified input ports.

Usage

```
add_loadboard_loopback_pairs -inputs {input_object_spec} -outputs {output_object_spec}  
    [-ac_delay_to_z ac_delay_to_z]
```

Description

This command creates a loopback connection from specified output ports to corresponding specified input ports. Loopback connections that are specified on compatible ICL ports are also added to the ICL data model during the next system mode transition into analysis mode. The following ICL port pairs are compatible with loopback connections: ScanOutPort to ScanInPort, DataOutPort to DataInPort and ToClockPort to ClockPort. An `ac_delay` time can be specified for the connections. This command provides direct connections of the DC and the CouplingCapacitor connections in the simulation testbenches of custom pattern (using `open_pattern_set`, `close_pattern_set`, and `write_patterns`).

Arguments

- **-inputs** {*input_object_spec*}
 - **-outputs** {*output_object_spec*}
 - **-ac_delay_to_z** *ac_delay_to_z*
- A required switch and string pair that specifies the input ports for a loopback connection. The *input_object_spec* string can specify one or more input ports that get paired with an output port specified in the **-outputs** *output_object_spec* switch. If the input port count does not match the output port count, the tool issues an error.
- A required switch and string pair that specifies the output ports for a loopback connection. The *output_object_spec* string can specify one or more output ports. The output ports specified get paired with an input port specified in the **-inputs** *input_object_spec* switch. If the output port count does not match the input port count, the tool issues an error.
- An optional switch and value pair that specifies the ac-delay-to-z value for all the loopback connections made in by this command. The value must be a valid time specification such as 10ns. This value triggers the creation of a coupling capacitor that tri-states (Z) the signal going back to the input after the amount of time on each level transition of the output signal.

Examples

This example shows how this command is used to create a loopback pairs between two outputs and inputs. An `ac_delay` of 10ns is specified. The first output, `dout[5]`, listed in the `-outputs` switch is connected to the first input, `din[4]`, listed in the `-inputs` switch:

```
add_loadboard_loopback_pairs -inputs {din[4] ue} -outputs {dout[5] dout[0]} \  
-ac_delay_to_z 10ns  
report_loadboard_loopback_pairs
```

```
-----  
Inputs  Outputs  AC Time to Z  
-----  
din[4]  dout [5]   10ns  
ue      dout [0]   10ns  
-----
```

```
write_patterns pat.v -pattern_sets pat1 -verilog
```

The following statements are added to the Verilog file.

```
wire to_din_4_;  
assign to_din_4_ = \din[4] ;  
CouplingCapacitor #(10.000000) din_4__CC_INST(.in(\dout [5] ),  
.out(to_din_4_));  
  
wire to_ue;  
assign to_ue = ue;  
CouplingCapacitor #(10.000000) ue_CC_INST(.in(\dout [0] ), .out(to_ue));
```

add_misrs

Context: patterns -scan

Mode: setup, analysis

Specifies the MISR structure and initial seed.

Usage

```
add_misrs misr_name -size integer [-seed hexadecimal] [-taps index...]
```

Description

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

This command is included in the LogicBIST fault simulation dofile to describe the MISR logic synthesized.

Arguments

- *misr_name*
A required string that specifies the name of the MISR. The *misr_name* is subsequently used by the tool for referring to this MISR for specifying connections from scan chains, and in reporting.
- -size *integer*
A required switch and integer that specifies size of the MISR.
- -seed *hexadecimal*
An optional switch and hexadecimal number pair that specifies the initial seed. Use this command if you intend on performing fault simulation with a different starting MISR seed.
- -taps *index*
An optional switch and repeatable integers that specifies the tap points for the MISR feedback network. The tap index starts from 1 to be consistent with the decompressor used as a PRPG in the LogicBIST mode and associated decompressor commands.

Examples

This example shows the add_misrs command in context patterns -scan, mode setup. This example adds a 24-bit MISR named “misr” with initial seed of all 0-s:

```
add_misrs misr -size 24 -seed 000000 -taps 21 22 24
```

add_nofaults

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Places nofault settings either on pin pathnames, pin names of specified instances, or modules.

Usage

```
add_nofaults {modulename ... -Module [-PIN module_pin_pathname ...] |  
  object_expression ... [-PIN | -Instance]} [-Stuck_at {01 | 0 | 1}] [-Keep_boundary]} | -Wire  
  [-VERBose] [(> | >>).file_pathname]
```

Description

By specifying pathnames of pins, instances, or modules while in Setup mode, the add_nofaults command places a nofault setting either on the specific pins or on boundary and internal pins of the instances or modules. All added nofault pin pathnames are in the user class.

Note

 All switches except -Wire are valid only before flattening. The -Wire switch is valid only after flattening.

The -Stuck_at switch applies to either stuck-at faults or transition faults. For the latter, you specify 0 for “slow-to-rise” and 1 for “slow-to-fall” transition faults. If you do not specify a value, then the tool places a nofault setting on both stuck-at (transition) values. If you add faults with the add_faults command after you issue the add_nofaults command, the specified pin pathnames or boundary and internal pins of instances or modules cannot be sites for those added faults.

Note

 When you add nofault settings, the tool deletes the flattened simulation model if it exists. This removes information you added after model flattening, such as ATPG functions. To avoid losing this information or having to wait for the tool to flatten the design again, add nofault settings prior to model flattening.

Arguments

- ***modulename***
A repeatable string that specifies the name of a module to which you want to assign nofault settings. You must include the -Module switch when you specify a module name.
- **-Module**[-PIN *module_pin_pathname* ...]
A switch that specifies to interpret the ***modulename*** argument as a module pathname. All instances of the module are affected. You can use the asterisk (*) and question mark (?) wildcards for the ***modulename*** argument, and the tool adds the nofault for all matching modules or library models.

When you follow the -Module switch with the optional -PIN switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given module name and adds nofaults for every pin specified in module_pin_pathname list.

- ***object_expression***

A string representing a list of pathnames of instances or pins for which you want to assign nofault settings. You can use regular expressions, which may include any number of asterisk (*) and question mark (?) wildcard characters.

Pin pathnames must be Tessent Cell library cell instance pins, also referred to as design level pins. If the object expression specifies a pin within an instance of a Tessent Cell library model, the tool ignores it. By default, pin pathnames are matched first. If a pin pathname match is not found, the tool next tries to match instance pathnames. You can force the tool to match only pin pathnames or only instance pathnames by including the -Pin or -Instance switch after the *object_expression*.

- -PIN

An optional switch that specifies to use the preceding object expression to match only pin pathnames; the tool then assigns nofault settings to all the pins matched.

- -Instance

An optional switch that specifies to use the preceding object expression to match only instance pathnames; the tool then assigns nofault settings to all boundary and internal pins of the instances matched (unless you use the -Keep_boundary switch).

- -Stuck_at 0 | 0 | 1

An optional switch and literal pair that specifies to which stuck-at or transition values you want to assign a nofault setting. The choices are as follows:

0 — A literal that specifies to place a nofault setting on both the “stuck-at-0” and “stuck-at-1” faults for stuck-at faults; or on both the “slow-to-rise” and “slow-to-fall” faults for transition faults. This is the default.

0 — A literal that specifies to place a nofault setting on only the “stuck-at-0” faults for stuck-at faults; or on only the “slow-to-rise” faults for transition faults.

1 — A literal that specifies to place a nofault setting on only the “stuck-at-1” faults for stuck-at faults; or on only the “slow-to-fall” faults for transition faults.

- -Keep_boundary

An optional switch that specifies to apply nofault settings to the inside of the specified instance/module, but permit faults at the boundary pins of these instances/modules. This option does not apply to nofaults on pin pathnames.

- -Wire

A switch that specifies for the tool to no-fault a cone of logic fanning out from a stem forward into a single wire gate. The tool no-faults the entire cone of logic between the stem

and the wire gate, but not the stem or the output of the wire gate. There must be no other fanout from this cone of logic. This switch is valid only after flattening.

Note

 This switch affects all qualifying logic cones.

- **-VERbose**

By default when you specify wildcard characters for instance (-INstance) or pin (-PIN) names, the tool outputs a summary message similar to the following:

```
// Note: Adding nofaults for 330 fault sites.
```

When you specify the optional -VERbose switch, then the tool outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the > or >> redirection operators.

If you use actual instance or pin names instead of wildcards, then this switch has no effect.

- **> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- **>> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

The following example defines nofault settings for all the pins in a particular instance, so when you add all faults to the circuit for an ATPG run, the tool does not place faults on the pins of that instance:

```
add_nofaults i_1006 -instance  
set_system_mode analysis  
create_patterns
```

add_nonscan_instances

Context: dft -no_rtl, dft -rtl, dft -scan, dft -test_points

Mode: setup, analysis

Sets a user-specified is_non_scannable attribute on the specified design objects.

Usage

Context: dft -scan, dft -test_points, dft -no_rtl

```
add_nonscan_instances { -INStances instance_spec | -Modules module_spec |  
-scan_elements scan_element_spec | -Control_signals pin_spec | -All  
-unmapped_flop_cells} [-force]
```

Context: dft -rtl

```
add_nonscan_instances { -INStances instance_spec | -Modules module_spec |  
-scan_elements scan_element_spec | -Control_signals pin_spec |  
-rtl_reg net_spec | -All } [-force]
```

Description

Sets a user-specified is_non_scannable attribute on the specified design objects, thus excluding them from the scan insertion process.

The add_nonscan_instances command sets the user-specified is_non_scannable attribute on the specified instances, all sequential cells within the instances of the specified modules, the specified scan elements, the instances controlled by the specified control signals, or all instances.

Also, the tool does not perform the scannability rule checks on non-scan instances.

When adding non-scan instances with control signals, the tool adds all sequential instances controlled by the control signals to the non-scan instance list. Control pins can be any clock, set, or reset signal (primary input) that controls the contents of sequential instances. You can use the [report_control_signals](#) command to see the pins that control the sequential instances in the design.

If TIE0 and TIE1 non-scan cells are scannable, they are considered for scan. However, if these cells are used to hold off sets and resets of other cells so that another cell can be scannable, you must use this command to make them non-scan.

The add_nonscan_instances command may invalidate data from other analysis stages. This command should be used before any X-bounding analysis, wrapper analysis, or scan chain analysis. If you have already completed any of these steps when you issue the add_nonscan_instances command, it results in an error. You can use the -force switch to override it, in which case the results of X-bounding analysis, wrapper analysis and scan chain analysis is reset and you must repeat them.

Arguments

- **-INStances** *instance_spec*

An optional switch and value pair that causes the tool to ignore the specified instances during scan insertion. The *instance_spec* can be a Tcl list of one or more instances or a collection of one or more instances. If the instance is hierarchical, then all instances beneath it are also flagged as non-scan.

- **-Modules** *module_spec*

An optional switch and value pair that causes the tool to ignore all sequential cells within the instances of the specified modules during scan insertion. The *module_spec* can be a Tcl list of one or more modules or a collection of one or more modules. Note: module may specify the name of a Verilog module, or a Tessent library model.

- **-scan_elements** *scan_element_spec*

An optional switch and value pair that causes the tool to explicitly ignore the specified scan elements during scan insertion. The *scan_element_spec* can be a Tcl list of one or more scan elements or a collection of one or more scan elements.

Note

In analysis mode, this option is only available for leaf scan elements that are not part of a scan segment of a scan chain.

- **-Control_signals** *pin_spec*

An optional switch and value pair that causes the tool to ignore the instances controlled by the specific control signals. The *pin_spec* can be a Tcl list of one or more pins or a collection of one or more pins. You can only use the **-Control_signals** option in analysis mode.

- **-rtl_reg** *net_spec*

An optional switch and value pair that specifies a Tcl list of one or more net names or a collection of one or more net objects. During quick synthesis, if the net ends up being synthesized to a flip-flop, the net ends up being directly connected to the Q pin of a DFF cell. The `is_non_scannable` attribute value is automatically transferred to the DFF cell instance. The `is_non_scannable_reason` attribute for these DFT cell instances returns `user_specified_from_net`. This switch is only available in the `dft -rtl` context (with no sub-contexts). Use this switch when you want to declare an RTL register to be treated as non-scannable during DRC. You cannot specify the `add_nonscan_instances` command on the DFF cell instances directly because they do not exist before the quick synthesis has happened when going from setup to analysis mode.

- **-All**

An optional switch that marks every scan cell in the design as a non-scan cell. When you issue the command with the **-All** switch, the tool completely clears the list of targeted cells, and you can then manually select an arbitrary subset of target cells using the [add_scan_instances](#) command.

add_nonscan_instances

- **-unmapped_flop_cells**
An optional switch that marks every flop cell not already mapped to a scan cell in the design as a non-scan cell.
- **-force**
An optional switch that directs the tool to forcefully issue the `add_nonscan_instances` command. In order to avoid using invalidated data, the tool resets the results of any X-bounding analysis and wrapper analysis and delete all the scan modes and scan chain families. It is recommended that you re-run X-bounding and wrapper analysis and set the scan modes and scan chain families as needed after you issue the `add_nonscan_instances` command.

Examples

Example 1

The following example specifies that the tool ignore the sequential `i_1006` instance when identifying and inserting the required scan circuitry:

```
add_nonscan_instances -instances i_1006
```

Example 2

The following example clears all previously identified scan cells and then adds two instances to the list of scan cells to be stitched:

```
add_nonscan_instances -all  
add_scan_instances -instances i_1006 i_1007  
insert_test_logic
```

Related Topics

add_notest_points

Context: dft -scan, dft -test_points

Mode: setup, analysis

Prevents test logic insertion in the specified regions.

Usage

```
add_notest_points [-Control_only] [-OBserve_only]
    {pin_pathname... | instance_pathname... | instance_expression} | -Path filename
```

Description

The `add_notest_points` command is used to mark specific regions of the design to be excluded when inserting test logic (control points, observe points, fixing bidirectionals, set/reset, x-bounding and clock lines). This command is maintained to provide backward compatibility with previous versions of the tool, but the `no_control_point` and `no_observe_point` attributes actually provide a more flexible mechanism for accomplishing this task.

Internally, the `add_notest_points` command sets the `no_control_point` and `no_observe_point` attributes to `True` for the specified `pin_pathname`, `instance_pathname`, or `instance_expression`. When an instance is specified, the attribute is set only for that specific instance and not for any child instances because this is automatically covered by inheritance.

If you specify a path file that contains delay paths, the tool marks each gate pin in the path by setting the `no_control_point` and `no_observe_point` attributes on each gate pin. This prevents control and observation points from being added to a critical path and thus prevents increasing the load on any of these gates in that path. The format of the file is the same as the file loaded with the `read_fault_sites` command. For more information on the format, refer to “[The Path Definition File](#)” in the *Tessent Scan and ATPG User’s Manual*.

The `report_notest_points` command displays all the pins in this list or can list the defined critical paths.

Arguments

- `-Control_only`
An optional switch that specifies that no control points are added in the specified regions.
- `-OBserve_only`
An optional switch that specifies that no observe points are added in the specified regions.

Note

 By default, this command prevents the insertion of both control and observe points.

- ***pin_pathname***

A required, repeatable string that lists the pins that you do not want to use for insertion of controllability and observability.

- ***instance_pathname***

A repeatable string that lists the instances whose pins you do not want to use for controllability and observability insertion. All pins within that (hierarchical) instance are added to the list of pins that should be excluded from consideration.

- ***instance_expression***

A string representing a list of instances within the design. The string *instance_expression* is defined as:

```
{ string | string * } ...
```

The asterisk (*) is a wildcard that matches many instances in a design. Any expression that does not contain an asterisk (*) matches exactly zero or one instance.

This argument does not support pathnames to objects below the instance level of a Tessent Cell library model. You can use a pathname expression to select several instances and the tool then runs `add_notest_points` for all the pins on those instances; but if the expression specifies a location below the instance level of a Tessent Cell library model, the tool reports an error message.

- ***-Path filename (dft -test_points context only)***

A switch and filename pair that specifies the pathname to a file that contains critical path information. For more information on the format of the file, refer to “[The Path Definition File](#)” in the *Tessent Scan and ATPG User’s Manual*.

Examples

The following example specifies output pins that the tool cannot use for testability insertion:

```
add_notest_points i_1006/o i_1008/o i_1009/o
```

Related Topics

[delete_notest_points](#)

[set_test_point_insertion_options](#)

[report_notest_points](#)

add_observe_points

Context: dft -test_points

Mode: setup, analysis

Specifies user-defined observe points during test point insertion.

Usage

```
add_observe_points -location pin/port_spec  
    [-clock pin/port_spec]  
    [-enable pin/port_spec]
```

Description

Specifies user-defined observe points during test point insertion.

Arguments

- **-location** *pin/port_spec*
A required string that specifies the pathname to the observe point location where *pin/port_spec* can be a Tcl list of one or more pins/ports or a collection of one or more pin/port objects.
- **-clock** *pin/port_spec*
An optional switch and string pair that specifies the path name of the clock signal used to clock the observe point. This can be a collection or list, but should have only one element.
- **-enable** *pin/port_spec*
An optional switch and string pair that specifies the path name of an existing net used to enable the observe point. This can be a collection or list, but should have only one element.

If you want to specify the default enable signal for the automatically identified observe points instead of manually adding each enable signal, use the [set_test_point_insertion_options](#) command as follows:

```
set_test_point_insertion_options -observe_points_enable
```

Examples

Example 1

The following example adds two observe points, and specifies the new scan cell model used to observe the inserted test points:

```
add_observe_points -location ss1/ix348/Z
```

```
add_observe_points -location ss1/ix302/Z
```

Example 2

The following example specifies the path names of existing nets that are to be used to enable the control points and observe points respectively. Then it adds a control point and an observe point, and proceeds to insert the test points into the netlist:

```
set_test_point_insertion_options -control_point_enable cp_enable \  
    -observe_point_enable op_enable  
  
add_control_points -location jtc/i1216/OUT -type and  
add_observe_points -location jtc/i1645/OUT  
  
...  
set_system_mode analysis  
  
...  
insert_test_logic
```

add_output_masks

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Ignores any fault effects that propagate to the primary output pins you name.

Usage

add_output_masks *primary_output...* | **-All**

Description

patterns -scan Details

The tool uses primary output pins as the observe points during the fault detection process. When you mask a primary output pin, you inform the tool to mark that pin as an invalid observation point during the fault detection process. This command enables you to flag primary output pins that do not have strobe capability. The tool classifies the faults whose effects only propagate to that observation point as ATPG_untestable (AU).

dft -scan Details

The tool uses primary output pins as the observe points during the scan identification process. When you mask a primary output pin, you inform the tool to mark that pin as an invalid observation point during the identification process.

There are specific design practices that mask specific primary output pins in order to group the sequential elements associated with those primary outputs (for example, if you are using wrapper chains). For more information on wrapper chains, refer to “[About Wrapper Chains](#)” in the *Tessent Scan and ATPG User’s Manual*.

You can set a default mask for all output and bidirectional pins using the [set_output_masks](#) command. You can add a hold value to a default mask with the add_output_masks command, or remove a hold value using the [delete_output_masks](#) command. To turn off the default masks for all output pins, you must use the [set_output_masks](#) command with the Off literal.

When you use the add_output_masks command in the dft -scan context, the wrapper analysis for that pin is excluded.

Note

 The pin constraints added when you use this command can be deleted using the delete_output_masks command. Pin constraints added in setup mode cannot be deleted in analysis mode and vice versa.

Arguments

- *primary_output*
A repeatable string that specifies the name of the primary output pin you want to mask.
- **-All**
A switch that specifies to mask all primary output pins.

Examples

The following example specifies the primary output pins that do not have the strobe capability on the hardware tester:

```
add_output_masks qb1 qb2 qb3
```

add_pattern_trigger

Context: patterns -silicon_insight

Mode: all modes

Adds a trigger for additional equipment for measurement at a specific pattern location. This command applies only to OpalKelly adapters using smart mode.

Usage

add_pattern_trigger *pattern_name* -vector_address *vector_address* [-type *type*]

Arguments

- *pattern_name*
A required string that specifies the name of the pattern in which to add the trigger.
- -vector_address *vector_address*
A required switch and nonnegative integer that specifies the vector address for the trigger. For XEM6310, the pin position is AB9. For XEM8350, the pin position is AJ39.
- -type *type*
An optional switch and string that specifies the type of the trigger. This describes the waveform on the trigger pin. The legal value for the type is “pulse”.

add_primary_inputs

Context: all contexts

Mode: setup

Adds a primary input (PI) also known as an input pseudo_port to the specified pins or nets.

Usage

```
add_primary_inputs pin_or_net_pathname... [-pseudo_port_name user_name]  
[-silent]
```

Description

Adds an input pseudo_port to the specified nets or pins. This command also designates the pseudo_port as user-class primary inputs (PI) rather than system-class PIs described in the original netlist. By default, the tool appends the names of these created pseudo ports with suffix “_pport”. This is done to distinguish the pseudo port from the internal pin path name and avoid creating two gates with the same name.

If -pseudo_port_name *user_name* is specified, then the pseudo port name is the *user_name* as is. No “_pport” suffix is added.

When you issue the command, the tool disconnects the original drivers of the net such that the added PI becomes the only driver of the pin or net. The tool omits these PIs from the top-level interface when saving patterns.

Note

 The tool does not fault PIs created with this command. This enables interchange of fault lists between runs of the tool across different modes where you may have used different cut points.

When you use the [write_patterns](#) -Mode_internal switch when saving serial or parallel simulation patterns, the test bench still forces the internal nodes on *pin_or_net_pathname* even though the corresponding PIs are not included in the top-level interface. When you save the patterns using the -Mode_external switch, the test bench does not force those internal nodes. In this case, unless the circuit generates values on the internal nodes corresponding to what ATPG assumed was forced on the corresponding PIs, you may get simulation mismatches.

Use the -pseudo_port_name switch to specify a list of internal pin pathnames to connect to a single, new primary input pin. You can display the user-class, system-class, or full-class PIs by using the [report_primary_inputs](#) command.

Arguments

- ***pin_or_net_pathname***
A required, repeatable string that specifies the pathname of a pin or net to which you want to add a primary input. The *pin_or_net_pathname* may include any number of asterisk (*) and question mark (?) wildcard characters in a name.
- **-pseudo_port_name *user_name***
An optional switch and string pair that specifies the name for a new primary input pin name that drives all the internal pins specified with the *pin_or_net_pathname* argument. The *user_name* must be a simple name that begins with an alpha character and can contain only alphanumeric characters and underscore characters ('_'). Wildcards are not permitted.
- **-silent**
An optional switch that suppresses the transcription of notes the tool issues.

Examples

Example 1

The following example adds two new primary inputs to the circuit and places them in the user class of primary inputs:

```
add_primary_inputs indata2 indata4
```

Example 2

The following examples demonstrate various uses of the `add_primary_inputs` command:

```
SETUP> add_primary_inputs final_carry/A0 // cell input  
// Warning: Primary input 'final_carry/A0_pport' is added at pin  
// '/final_carry/A0'  
  
SETUP> add_primary_inputs final_carry/Y // cell output  
// Warning: Primary input 'final_carry/Y_pport' is added at pin  
// '/final_carry/Y'  
  
SETUP> add_primary_inputs ha1/a // module input  
// Warning: Primary input 'ha1/a_pport' is added at pin '/ha1/a'  
  
SETUP> add_primary_inputs ha1/s // module output  
// Warning: Primary input 'ha1/s_pport' is added at pin '/ha1/s'  
  
SETUP> report_primary_inputs -class user  
USER:      '/ha1/s_pport' (internal pin)  
USER:      '/ha1/a_pport' (internal pin)  
USER:      '/final_carry/Y_pport' (internal pin)  
USER:      '/final_carry/A0_pport' (internal pin)
```

Example 3

The following example adds a PI to the net originally driven by the output of a NAND gate, disconnecting the output of the NAND from the net. This happens within the tool only; the tool does not modify the original source netlist.

```
set_gate_level primitive  
create_flat_model  
report_gates /ix157/Y  
  
// /ix157 (94) NAND  
// A0 I 25-/reg_0_/Q  
// A1 I 33-/reg_1_/Q  
// Y O 142-/d_2_mult_0_/A1  
  
add_primary_inputs /ix157/Y  
report_gates /ix157/Y  
  
// /ix157 (95) NAND  
// A0 I 26-/reg_0_/Q  
// A1 I 34-/reg_1_/Q  
// Y O
```

Example 4

The following example connects internal nets “xyz/abc/pina xyz/def/pina xyz/ghi” to a single, new primary input and disconnects the original drivers of the nets, making the added primary input the only driver of the nets. This is the default behavior. The name of the new primary input pin is “group_pi”.

```
add_primary_inputs xyz/abc/pina xyz/def/pina xyz/ghi -pseudo_port_name group_pi
```

add_primary_outputs

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Adds primary outputs (PO) to the specified net.

Usage

```
add_primary_outputs pin_or_net_pathname... [-pseudo_port_name user_name]  
[-silent]
```

Description

The `add_primary_outputs` command adds an additional primary output to each specified pin or net. Once added, the tool defines them as user-class primary outputs. These primary outputs are not added to the top-level interface when saving mode_external patterns, such as STIL and WGL.

Note

 The tool does not fault POs created with the `add_primary_outputs` command. This enables interchange of fault lists between runs of the tool across different modes where you may have used different cut points.

The tool defines the primary outputs described in the original netlist as system class primary outputs. You can display the user class, system class, or full classes of primary outputs using the [report_primary_outputs](#) command.

Arguments

- *pin_or_net_pathname*
A required, repeatable string that specifies the pin or net to which you want to add primary outputs. The *pin_or_net_pathname* may include any number of asterisk (*) and question mark (?) wildcard characters in a name.
- `-pseudo_port_name` *user_name*
An optional switch and string pair that specifies the name for a new primary output pin name that is driven by the internal pin specified with the *pin_or_net_pathname* argument. The *user_name* must be a simple name that begins with an alphabetic character and can contain only alphanumeric and underscore characters ('_'). Wildcards are not valid.
- `-silent`
An optional switch that suppresses the transcription of notes the tool issues.

Examples

The following example adds a new primary output to the circuit and places it in the user class of primary outputs:

```
add_primary_outputs outdata1
```

add_processors

Context: unspecified, dft -edt, patterns -scan

Mode: setup, analysis, insertion (dft -edt context only)

Enables the tool to run multiple processors in parallel on multiple machines to reduce runtime.

Usage

add_processors {*hostname*[:{*cpus* | MAXcpu}]}...

Description

The add_processors command enables the tool to use multiple processors simultaneously on specified host machines when running multiprocessing commands for ATPG or fault simulation. Remote processes can be created on the primary host and on other hosts. Each process, whether on the primary or secondary host, can optionally use multiple processors through multithreading.

For more information, refer to “[Multiprocessing for ATPG and Simulation](#)” in the *Tessent Scan and ATPG User’s Manual*.

Running multiple processes in parallel can sometimes reduce runtime significantly, especially for large designs. Be sure to load your design in the tool before using the add_processors command. By doing this, the tool more accurately estimates memory requirements for the added processes.

Typically, the tool runs as a single primary process. When you make additional processors available with the add_processors command, there exists a single primary process. The tool then starts additional secondary processes and adds additional processors (threads) to existing processes. This enables parallel running and coordination of communication between all processors.

Multiprocessing commands that use remote processes alert you with a message when the design is being sent to remote processors. This message may not appear during subsequent commands if the remotes have already received the design and you have issued no commands in the interim that would affect the information received. There is currently a limit of 1024 processors per add_processors command.

Tip

 To stop the command from waiting any longer for requested remote processes not yet received, and proceed with those it has, use the Control-C key sequence.

Arguments

- *hostname*

A required, repeatable string or literal that specifies a host machine or job scheduler that the tool can use for remote processes.

The hostname choices are as follows:

machine_name — A string that specifies a host machine by its network name.

LOCALHOST — A literal that specifies to use the machine you invoked the tool on as the host machine.

IPaddress — A string that specifies a host machine by its IP address.

LSF — A literal that specifies to use available Load Sharing Function (LSF) host machines.

SGE — A literal that specifies to use available Sun Grid Engine (SGE) host machines.

GENERIC — A literal that specifies to use a host machine as determined by a custom job scheduler. This option requires that you first issue a [set_multiprocessing_options](#) command with the `generic_scheduler` argument to inform the tool how to launch the custom job scheduler.

Note

 When you add SGE or LSF remote hosts with the `add_processors` command, the tool estimates the available host memory and swap space needed for the remotes based upon the current memory usage of the tool and the number of requested processors. The tool includes these requirements in its requests for processors from the grid system. For this reason, it is best that you specify any setup commands that may have significant effects on memory usage (such as leaving setup mode and reading SDC and SDF files) prior to using the `add_processors` command. In the Tessent Shell tool, the design should be loaded before adding remote processors.

Note

 The use of job schedulers requires certain environment prerequisites to be satisfied before you invoke the tool. See “[Multiprocessing Requirements](#)” in the *Tessent Scan and ATPG User’s Manual* for more information.

- `{cpus | MAXcpu}`

A colon (:) followed by a positive integer or the `MAXcpu` keyword allows you to optionally specify the number of processors to use on the specified host machine or through a job scheduler. You can specify up to 32 processors per host. The tool gives a warning if you specify 0 processors.

If you specify a positive integer, the tool adds that number of processors.

If using a job scheduler, the tool uses as many processors as the scheduler provides in the time allotted. The time allotted is determined by the setting of the `scheduler_timeout` variable, which you can change using the [set_multiprocessing_options](#) command.

If you specify the `MAXcpu` keyword, the tool automatically determines the number of physical processors on the specified host and adds enough additional processors to bring the total number of running processors on that host up to the number of physical processors. The default for the LSF scheduler is 8 processors while the default for all others is 1 processor.

Note

 The MAXcpu keyword does not apply to grid scheduling or generic scheduling. The tool's cpu calculations are based on currently running processors without considering other remote processor specifications on the same command line. For example, if you use the MAXcpu keyword twice in the same command for a given host, the number of remote processors on that machine could exceed the number of available processors.

Examples

Example 1

The following example adds processors to the primary host, which increases the thread count instead of adding additional remotes (unless multithreading has been turned off with the `set_multiprocessing_options` command):

```
add_processors localhost:4 ;  
# adds 4 threads to the primary process for a total thread count of 5  
  
// Adding 4 threads to birdeye (primary process)  
// Primary process with 5 threads running.  
  
report_processors  
  
// hosts          threads  arch      CPU(s)    %idle    free RAM  process size  
// -----  
// birdeye (primary)      5  x86-64  8 x 2.9 GHz    89%    113.91 MB  232.56 MB  
// Primary process with 5 threads running.
```

Example 2

The following example starts a distributed remote process on the remote host “odin” that runs with four total threads. The `add_processors` command normally starts only one process per remote host, and adds additional processors (to primary or secondary host) as additional threads. (Exception: If multithreading is turned off with the `set_multiprocessing_options` command, `add_processors` creates multiple single-threaded remotes.)

```
add_processors odin:4  
  
// Adding 4 threads to odin (new secondary process)  
// Primary process with 1 thread and 1 secondary process with 4 threads running  
/ (5 total threads).
```

add_read_controls

Context: `dft -edt`, `dft -scan`, `dft -test_points`, `patterns -scan`, `patterns -scan_retargeting`, `patterns -scan_diagnosis`

Mode: setup

Specifies the off-state value for specified RAM read control lines.

Usage

`add_read_controls {0 | 1} pin_pathname...`

Description

The `add_read_controls` command defines the circuit read control lines and assigns their off-state values. The off-state value of the pins or ports that you specify must be sufficient to keep the RAM outputs stable. The following are considerations for using this command:

- When the read control is already added as a clock, there is no need to also use `add_read_controls` for that port. This is the typical case, which means that for most usage it is unnecessary to explicitly use the `add_read_controls` command.
- If you want to have NR (non-clock) timing for read control lines that drive level-sensitive RAMs, you must add the read control using the `add_read_control` command; otherwise, the read control cannot pass DRC. NR timing for read control is not common.
- If a port drives the clock port of an edge-triggered RAM, the tool automatically infers that the port is a clock and adds it to the clock list. This is regardless of whether you added the port as a read control or not. For clocks that the tool infers, you must ensure that your timeplate includes the waveform for the newly defined clock.

Arguments

- **0 | 1**
A required literal that specifies 0 or 1 as the off-state value for the RAM read control lines.
- ***pin_pathname***
A required, repeatable string that specifies the pins or ports you want to designate as RAM read control lines, and to which you are assigning the given off-state value.

Examples

The following example assigns an off-state value of 0 to two read control lines, `r1` and `r2`:

```
add_read_controls 0 r1 r2
set_system_mode analysis
create_patterns
```

[report_read_controls](#)

add_register_value

Context: all contexts

Mode: setup

Creates a static or dynamic variable through which you specify a register identifier, *value_name*, and, optionally, the state string, *value_string*.

Usage

```
add_register_value value_name {[value_string [-Dynamic]  
  [-Radix {Binary | Decimal | Octal | Hexadecimal}] {-Width integer} |  
  {-Pattern_count {SCan_test | CHain_test | ALI}}}  
  [-LSB_shifted_first] [-INput_pin_inversion] [-OUtput_pin_inversion]
```

Description

When you specify a *value_string*, the variable is static by default unless you use the -Dynamic switch.

See “[Serial Register Load and Unload for LogicBIST and ATPG](#)” in the *Tessent Shell User’s Manual* for complete information.

Arguments

- *value_name*
A required string that specifies register value variable. The variable holds a value to load into the register. The register value variable is used in the procedure file to load the value into a register through the data input pin.
- *value_string*
An optional state string whose default radix is binary. You can specify Z or X values in addition to numerical values appropriate for the radix. When you specify a *value_string*, the variable is static by default unless you use the -Dynamic switch. You cannot specify a *value_string* when you use the -Pattern_count switch.
- -Dynamic
An optional switch that forces the variable to be dynamic when you provide an optional *value_string*. By default, when you provide a *value_string*, the variable is static.
- -Radix {Binary | Decimal | Octal | Hexadecimal}
An optional switch and literal that specifies the radix of the *value_string*. If you specify the -Radix switch, then you must specify the register width using the -Width switch.
- -Width *integer*
A switch and integer pair that specifies the register width. When defining a dynamic variable, you must use this switch.

add_rtl_to_gates_mapping

Context: all contexts

Mode: setup

Adds name-mapping rules for RTL to post-synthesis/post-layout name mapping.

Usage

```
add_rtl_to_gates_mapping [-register_name_prefix register_name_prefix]  
    [-register_name_suffix register_name_suffix ] |  
    [-instance_name_map_list string_pair_list]  
    [-port_name_map_list [port_name_mappings]  
    [-port_name_substring_map_list port_name_substring_mappings]
```

Description

This command enables adding extra name-mapping rules for RTL to post-synthesis/post-layout name mapping.

During the flow from RTL to the final gate-level netlist, the tool stores a number of files, for example, TCDs (Tessent Core Description), ICL files, and so forth. These files contain design instance path names, RTL register instance path names, and complex port names. During synthesis and layout, the RTL register names are mapped to flip-flop instances, the design hierarchy may be altered through grouping or ungrouping of various hierarchy levels, and complex port names are mapped to one-dimensional ports. To handle the renaming, the tool performs name mapping to find the objects in the netlist using the names they had in the RTL. By default, the tool is configured to handle most common name-mapping cases. If the default name-mapping rules are not sufficient, you must provide additional name-mapping rules using the `add_rtl_to_gates_mapping` command. You typically do not need to adjust the mapping rules unless you used “`ungroup -simple_names`” during synthesis as shown in the example below.

You use the following commands and switches to return a collection of pins, ports, or instances that use the RTL post-synthesis/post-layout name mapping:

- `get_instances -match_rtl_reg`
- `get_instances -use_path_matching_options`
- `get_pins -use_path_matching_options`
- `get_ports -use_path_matching_options`
- `get_ports -of_icl_ports`
- `get_pins -use_path_matching_options`

Arguments

- `-register_name_prefix` *register_name_prefix*
An optional switch and string pair that specifies a prefix to be applied before the first component of an RTL register name when performing introspection with the “`get_instances -match_rtl_reg`” command. The tool applies the same default matching rules described in the `get_pins` and `get_ports` commands.
- `-register_name_suffix` *register_name_suffix*
An optional switch and string pair that specifies a suffix that is applied after the first component of an RTL register name when performing introspection with the “`get_instances -match_rtl_reg`” command. The tool applies the same default matching rules described in the `get_pins` and `get_ports` commands.

The two preceding options are applied using the following name mapping rule:

```
<prefix>%name<suffix>{ [%d] }{ .%name{ [%d] } }
```

The elements of this syntax are:

```
<prefix>          - The value of the -register_name_prefix option.  
<suffix>          - The value of the -register_name_suffix option.  
<%name>           - A placeholder for a component name of a register name.
```

`{.%name{[%d]}}` - The component names and associated indices that follow the root name. The braces (`{}`) indicate that this portion of the rule maps to zero or more components of a register name.

The tool applies this name mapping rule to the name patterns of all invocations of the `get_instances` command that use the `-match_rtl_reg` option. After the tool transforms the name pattern with the name mapping rule, it matches it against the names in the netlist as described in “[Default Matching Rules for the `get_pins`, `get_ports`, and `get_instances -match_rtl_reg` Commands](#)” in the *Tessent Shell User’s Manual*.

The following default register name mapping rules are supported:

```
%name_reg{ [%d] }{ .%name{ [%d] } }  
rtlcreg_%name{ [%d] }{ .%name{ [%d] } }
```

You can apply both the prefix and suffix options in the same mapping rule. For example, given the following commands:

```
(1) add_rtl_to_gates_mapping -register_name_prefix "AAA_"  
(2) add_rtl_to_gates_mapping -register_name_suffix "_BBB"  
(3) add_rtl_to_gates_mapping -register_name_prefix "AAA_" \  
    -register_name_suffix "_BBB"
```

Rule 1 matches “`AAA_<registername>`”, and rule 2 matches “`<registername>_BBB`”. Rule 3 is needed to match “`AAA_<registername>_BBB`”.

Note

-  You cannot add prefixes and suffixes as regular expressions. The tool does not support wildcards in prefixes and suffixes.
-

- `-instance_name_map_list string_pair_list`

An optional switch and string pair list that specifies instance name-mapping rules. By default, you do not need to specify mapping because the tool already maps constructs such as “corea_i1/coreb_i1” to “\corea_i1/coreb_i1” and “corea_i1_coreb_i1”. Even a hierarchy path that is part of a generated block, such as “b1.b2[3].u2”, is automatically mapped to “\b1.b2[3].u2” and “b1_b2_3_u2”. If you used “`ungroup -simple_name`” to ungroup coreb_i1 into corea_i1, you must specify a mapping from “corea_i1/coreb_i2” to “corea_i2” as shown in the following example.

Note

-  You cannot use this option to specify name mapping for SystemVerilog interface instances.
-

- `-port_name_map_list port_name_mappings`

An optional switch and string pair list that specifies port name-mapping rules. The first name in a pair is the RTL or gate name that is to be mapped. When the introspection command is “`get_ports -of_icl_ports`” or “`get_pins -of_icl_pins`,” the first name must exactly match either the `tessent_design_gate_ports` or the `tessent_design_rtl_ports` attribute of the ICL object. When the introspection command is “`get_ports -use_path_matching_options`” or “`get_pins -use_path_matching_options`,” the first name must be an exact match with the port name argument or, in the case of `get_pins`, the pin name argument’s leaf name.

The second name in a pair is the new gate name to be looked up in the netlist. It must be an exact match with a port name in the netlist; that is, the default mapping rules described in “Default Matching Rules for the `get_pins`, `get_ports`, and `get_instances -match_rtl_reg` Commands” in the *Tessent Shell User’s Manual* are not applied when you use this option. Both names are complete bit-select port names, not components of a port name. Provide the mapping pair list as a flat list as follows:

```
{<name_to_be_mapped_1> <new_netlist_name_1>  
 <name_to_be_mapped_2> <new_netlist_name_2> ...  
 <name_to_be_mapped_n> <new_netlist_name_n>}
```

The number of names in the list must be an even number.

- `-port_name_substring_map_list port_name_substring_mappings`

An optional switch and string pair list that specifies substring mapping to be applied to the name being introspected. That name may be the value of the `tessent_design_gate_ports` or the `tessent_design_rtl_ports` attribute of the ICL object specified in a “`get_ports -of_icl_ports`” or “`get_pins -of_icl_pins`” command. Otherwise, it is the port name argument

of a “get_ports -use_path_matching_options” command or the leaf name of the pin name argument of a “get_pins -use_path_matching_options” command.

The option takes a list of substring pairs. If the first substring in a pair appears in the name being introspected, then all substring occurrences are replaced with the second substring in the pair. All substring pairs are applied to the name. At that point, the new name lookup occurs in the netlist. If the name is not found, the default mapping rules are applied as described in “Default Matching Rules for the get_pins, get_ports, and get_instances -match_rtl_reg Commands” in the *Tessent Shell User’s Manual*.

Provide the substring mapping pair list as a flat list as follows:

```
{<substring_to_be_replaced_1> <substring_replacement_1>  
 <substring_to_be_replaced_2> <substring_replacement_2> ...  
 <substring_to_be_replaced_n> <substring_replacement_n>}
```

Examples

Example 1

This example specifies whether objects within instance coreb_i1 were ungrouped into their parent instance corea_i1 using the “ungroup -simple_name” command by using add_rtl_to_gates_mapping command. The report_rtl_to_gates_mapping command invocation shows the added mapping. As described above, you typically never need to add mapping unless you have used the “ungroup -simple_name” command with your synthesis tool.

```
add_rtl_to_gates_mapping -instance_name_map_list {corea_i1/coreb_i1 corea_i1}
```

```
report_rtl_to_gates_mapping
```

```
// Index Register Name Prefix Register Name Suffix  
-----  
1  
2 rtlcreg_  
3  
// Index Original instance name Mapped instance name  
// -----  
// 1 corea_i1/coreb_i1 corea_i1
```

Example 2

This example maps the RTL design name of a port bit to the corresponding netlist name by using the add_rtl_to_gates_mapping command with the -port_name_map_list option. The default mapping rules are sufficient to perform needed mappings in most cases. This command

enables you to create a mapping when the default rules are unable to find a match. Consider the following design:

```
package defs;
  typedef struct packed {
    logic [1:0] joe;
    logic sam;
  } my_type1;
endpackage

module core (input defs::my_type1 clka);
  ...
endmodule
```

The clka port has three bits:

```
clka.joe[1]
clka.joe[0]
clka.sam
```

After renaming clka to clkz in Genus, the following appears in the netlist:

```
module core (\clkz[sam] , \clkz[joe] );
input \clkz[sam] ;
input [1:0] \clkz[joe] ;
...
endmodule
```

If the three bits of clka are ICL ports, you must provide mappings from the RTL name clka to the gate name clkz in the gate-level flow. These mappings must be at the bit level:

```
add_rtl_to_gates_mapping -port_name_map_list \
{{clka.joe[1]} {\clkz[joe] [1]} {clka.joe[0]} {\clkz[joe] [0]} \
{clka.sam} {\clkz[sam] }}
```

You must run this command before elaborating the design.

When you elaborate the design with “set_current_design core”, the tool uses these mappings to update the tessent_design_gate_ports attributes of the ICL ports clka[2], clka[1], and clka[0]. The three updated attribute values are as follows:

```
\clkz[joe] [1]
\clkz[joe] [0]
\clkz[sam]
```

To introspect the design port corresponding to the ICL port clk1[1], use the following commands:

```
set port1 [get_icl_ports clka[1] -of_modules core]  
get_ports -of_icl_ports $port1
```

The tool uses the tessent_design_gate_ports attribute of the ICL port (which is updated during set_current_design) to look up the corresponding design port in the netlist.

You can also perform the introspection with the following command:

```
get_ports clka.joe[0] -use_path_matching_options
```

The tool uses the mappings provided by the `add_rtl_to_gates_mapping` command to map the given name to the corresponding netlist name and look up the design port in the netlist.

Example 3

This example maps a substring in your RTL design name to a replacement substring by using the `add_rtl_to_gates_mapping` command with the `-port_name_substring_map_list` option. You may need to do this if you made such a replacement in your synthesis tool. Consider the following design:

```
module core( input joezz, input johnzz);  
...  
endmodule
```

After you replace all occurrences of “zz” with “yy”, the following appears in the netlist:

```
module core(joeyy, johnyy);  
  input joeyy;  
  input johnyy;  
  ...  
endmodule
```

If `joezz` and `johnzz` are ICL ports, you must provide a substring mapping that maps all occurrences of the substring “zz” to “yy” in the gate-level flow:

```
add_rtl_to_gates_mapping -port_name_substring_map_list {zz yy}
```

You must run this command before elaborating the design.

During elaboration of the design with the “`set_current_design core`” command, the tool updates the `tessent_design_gate_ports` attributes of the ICL ports `joezz` and `johnzz` with that mapping.

```
joeyy  
johnyy
```

To introspect the design port corresponding to the ICL port `joezz`, use the following commands:

```
set port1 [get_icl_ports joezz -of_modules core]  
get_ports -of_icl_ports $port1
```

The tool uses the `tessent_design_gate_ports` attribute of the ICL port (which is updated during `set_current_design`) to look up the corresponding design port in the netlist.

You can also perform the introspection with the following command:

```
get_ports joezz -use_path_matching_options
```

The tool uses the mappings provided by the `add_rtl_to_gates_mapping` command to map the given name to the corresponding netlist name and look up the design port in the netlist.

add_scan_chains

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Prerequisites: You must define the scan chain group with the add_scan_groups command prior to using this command.

Specifies a name for a pre-existing scan chain within the design.

Usage

```
add_scan_chains [-Internal | -Load_only] {chain_name group_name input_pin output_pin}...
```

For “dft -edt” context

```
add_scan_chains [-Internal] {chain_name group_name input_pin output_pin}...
```

Description

The add_scan_chains command defines a scan chain that exists in the design. A scan chain references the name of a scan chain group, which you must define prior to issuing this command.

A pre-existing scan chain is a serially connected set of scan cells that has been stitched together in a previous scan insertion operation, or that you created manually. In order for the tool to be able to correctly insert scan elements in the remainder of the design or to run rules checking on existing scan circuitry, you need to notify the tool of this circuitry, so it can treat those elements in the chain differently than the elements in the rest of the design.

When you use this command to notify the tool of a pre-existing scan chain, “dft -scan” context removes the scan cells in the scan chain from the eligible scan elements list. Because the tool removes the scan cells in the scan chain from the scan candidate list, the rules checker does not perform the usual scannability checks on those scan cells. However, the rules checker does perform additional rules checking based on the declaration of pre-existing scan elements that pertain to the checking of the validity and the operation of that scan chain.

If the design does have a pre-existing scan chain that you declare with the add_scan_chains command, you need to provide information on the operation of that scan chain in a test procedure file.

Arguments

- ***chain_name***
A required repeatable string that specifies the name of the scan chain to add to the specified scan group.
- ***group_name***
A required repeatable string that specifies the name of the scan chain group to add the specified scan chain to.

- ***input_pin***
A required repeatable string that specifies the input pin of the specified scan chain.
- ***output_pin***
A required repeatable string that specifies the output pin of the specified scan chain.
- **-Internal**
An optional switch that defines internal scan chains.

Note

 The **-Internal** switch specifies compressed scan chains when using Tessent TestKompress with EDT logic. Do not use it to define uncompressed scan chains (chains connected directly to a primary input and primary output and not driven by or observed through the Tessent TestKompress logic). See the “[Scan Chain Insertion](#)” section in the *Tessent TestKompress User’s Manual*.

- **-Load_only** (Not supported in the hybrid TK/LBIST flow)
An optional switch that specifies the definition of a load-only scan chain, which is an uncompressed scan chain with the following properties:
 - The scan input is a primary input.
 - The scan output is an internal pin that is specified only to enable scan chain tracing.

A load-only scan chain does not need to be unloaded, which saves chip-level pins and scan data. You can specify a load-only scan chain for special cases such as on-chip clock controllers that only need to be loaded but do not need to be unloaded.

The tool automatically adds OX constraints on all cells of the load-only scans that are not also in observable scan chains, using the cell masking mechanism, because those cells are not unloaded and observed. In the generated patterns or mode_external test bench, the internal scan chain outputs are ignored. These chains can be added with other normal scan chains, EDT blocks, or both. However, the load-only chains must be uncompressed and loaded only from ports, not a decompressor.

Note

 This switch does not support mapping EDT patterns to single bypass chain mode. Also, just like normal uncompressed chains, load-only uncompressed chains should not be added during the EDT IP phase.

Examples

Example 1

The following example defines two scan chains (chain1 and chain2) that belong to the scan group (grp1):

```
add_scan_groups grp1 atpg.testproc  
add_scan_chains chain1 grp1 si1 so1  
add_scan_chains chain2 grp1 si2 so2
```

Example 2

The following example shows add_scan_chains commands similar to those Tessent TestKompress would write in the *_edt.dofile dofile, during the IP Creation Phase, for the two scan chains of the preceding example. By default, the top level module name “/my_design” is prefixed to the pin names.

```
add_scan_groups grp1 *_edt.testproc  
add_scan_chains -internal chain1 grp1 /my_design/si1 /my_design/so1  
add_scan_chains -internal chain2 grp1 /my_design/si2 /my_design/so2
```

add_scan_groups

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies a group name for a set of pre-existing scan chains in a design.

Usage

```
add_scan_groups {group_name test_procedure_filename}...
```

Description

Specifies a group name for a set of pre-existing scan chains in a design. Only one group name can be specified per session.

If the design has pre-existing scan chains, those scan chains must belong to a scan group. The `add_scan_groups` command also specifies the corresponding test procedure file for that scan group. A sequence of procedures in the test procedure file defines the operation of the scan chains within a scan group. The scan group must have a corresponding test procedure file.

When needed, you can also use the `add_scan_groups` command to provide initialization values for non-scan memory elements. If the design does not have pre-existing scan chains and you need to initialize some non-scan memory elements for scannability checking, you can specify “dummy” as the `group_name` along with a `test_procedure_filename`. Then, within the test procedure file, you can use the optional `test_setup` procedure to initialize the non-scan memory elements. For complete information, see “[Test Procedure File](#)” in the *Tessent Shell User’s Manual*.

As a result, in `dft -scan` context, the tool models the non-scan memory elements as a TIE1 or TIE0.

Note

You must also define these same elements as non-scan using the [add_nonscan_instances](#) command.

Arguments

- ***group_name***
A required string that specifies the name of the scan chain group that you want to add to the system.
- ***test_procedure_filename***
A required string that specifies the name of the test procedure file that contains the information for controlling the scan chains in the specified scan chain group.

Examples

The following example defines a scan chain group, `group1`, which loads and unloads a set of scan chains, `chain1` and `chain2`, by using the procedures in the test procedure file, `atpg.testproc`:

```
add_scan_groups group1 ../data/atpg.testproc  
add_scan_chains chain1 group1 indata2 testout2  
add_scan_chains chain2 group1 indata4 testout4
```

Contents of `atpg.testproc` file:

```
timeplate gen_tp1 = force_pi 0 ;  
  measure_po 100 ;  
  pulse clk_ 200 100;  
  pulse tck 200 100;  
  pulse shift_clock 200 100;  
  pulse reset 200 100;  
  pulse refclk 200 100;  
  pulse ramclk 200 100;  
  period 400 ;  
end;  
  
procedure shift = scan_group grp1 ;  
  timeplate gen_tp1 ;  
  cycle = force_sci ;  
  measure_sco ;  
  pulse shift_clock ;  
  end;  
end;  
  
procedure load_unload = scan_group grp1 ;  
  timeplate gen_tp1 ;  
  cycle = force_clk_ 0 ;  
  force reset 0;  
  force ramclk 0 ;  
  force scan_enable 1 ;  
  end ;  
apply shift 16;  
end;  
  
procedure test_setup = scan_group grp1;  
  timeplate gen_tp1;  
  cycle = force test_logic_reset 1;  
  end;  
  cycle = force test_logic_reset 0;  
  end;  
end;
```

add_scan_instances

Context: dft -scan, dft -test_points

Mode: setup

Adds specified instances to the scannable instance list.

Usage

add_scan_instances **-INStances** *instance_spec* | **-Modules** *module_spec*

Description

When inserting scan chains, the add_scan_instances command ensures that the tool includes specific sequential instances in the scan list. The tool generates the scan list during the scan identification process. If the specified instance does not pass the rules checking process, it is not included in the identified scan list.

You can use the [delete_scan_instances](#) command to remove the exception status that you have attached to an instance with the add_scan_instances command. In this case, although the instance is converted back into a non-scan instance, the effects of its previous unknown state on downstream instances is not reset.

Note

 The add_scan_instances command can be used to override the default behavior for the S4 rule (when handling is set to Note), which forces cells with S4 violations to remain non-scan. Likewise, the add_scan_instances command can override the behavior of the S7 rule when its handling is set to Warning, which forces cells with S7 violations to remain non-scan. This provides a mechanism to override the S4 and S7 rule behavior for specific cells.

Arguments

- **-Instances** *instance_spec*

An optional switch and value pair that causes the tool to ignore the specified instances during scan insertion. *instance_spec* can be a Tcl list of one or more instances or a collection of one or more instances. If the instance is hierarchical, then all instances beneath it are also flagged as non-scan.

- **-Modules** *module_spec*

An optional switch and value pair that causes the tool to ignore all instances within the specified modules during scan insertion. *module_spec* can be a Tcl list of one or more modules or a collection of one or more modules. Note: module may specify the name of a Verilog module, or a Tessent library model.

Examples

The following example adds two sequential instances to the identified scan list and then runs the scan identification process.

```
add_scan_instances -instances i_1006 i_1007  
add_scan_mode int_mode -chain_count 10  
analyze_scan_chains  
insert_test_logic
```

[-si_pipelining { wrapper_chains_only | all_chains | off } ]  
[-si_pipelining_type { non_scan_flop | holding_scan_flop } ]
```

Description

Use this command to specify a chain scan mode, which defines one or more scan chains. Chain configurations specific to each scan mode are achieved by multiplexing scan path at certain inflection points computed by the scan insertion tool.

Arguments

- ***name***

A required string that uniquely describes the scan mode. When using DFT signals, if the specified scan mode name corresponds to the name of a DFT scan mode signal name, then the command implicitly infers both the type (-type) and the enable signal (-enable_dft_signal) for the mode; if the specified scan mode name does not match the name of a DFT scan mode signal, then you must specify the enable signal using the option “-enable_dft_signal” and the command implicitly infers the mode type (-type) from it.

- -chain_length { *integer* | unlimited }

An optional integer that specifies the target length of scan chains for a particular mode. By default, the tool imposes no limit (unlimited) on the chain length. The minimum scan chain length is 1.

- -chain_count { *integer* | unlimited }

An optional integer that specifies the number of scan chains that should be constructed for the specified mode. By default, the chain count is set to the number of connections specified with the -si/so_connections or by the number of pins of the EDT controller(s) specified with the -edt_instances option, otherwise if the latter options were not used, then no limit (unlimited) is imposed on the chain count.

- -type { internal | external | unwrapped }

An optional string and literal pair that specifies the type of scan mode. A mode of type external only considers wrapper scan elements in its default population, whereas internal and unwrapped modes consider all scan elements. For more information, see “[Unwrapped Cores Versus Wrapped Cores](#)” in the *Tessent Scan and ATPG User’s Manual*.

- -associate_chains *obj_spec*

An optional value that specifies a list of existing chains to associate in this mode but not included for scan distribution. It defaults to all usable existing chains when the mode type is “internal” or “unwrapped”, or to wrapper usable existing chains when the mode type is “external”.

Only scan_element objects with a state “usable” get added to a population; accordingly, it may be necessary to explicitly set the “active_child_scan_mode” attribute to specific child mode values to include the existing chains in a scan mode population.

This switch enables you to associate a specific subset of usable existing chains (or even an empty subset) with a scan mode instead of all the usable ones ([get_scan_elements -type chain]). You must include all existing chains of a mode connected to a given EDT controller when you use -associate_chains. Also, never include EDT segments/chains from different child modes in the same parent scan mode.

By default, the tool automatically associates usable existing chains to every “internal” or “unwrapped” mode, but only associates wrapper existing chains to “external” modes.

- `-include_chain_families obj_spec`

An optional value that specifies a list of chain families to include in this mode. It defaults to all chain families if no “`-include_`” option is specified.
- `-include_elements obj_spec`

An optional value that specifies a list of scan elements to include in this mode. It defaults to all scan elements if no “`-include_`” option is specified.
- `-enable_connections obj_spec`

An optional value that specifies one or more top-level port(s) or existing pin(s) to enable this mode. By default, the tool creates a scan_mode enable port with a name of the form “`ts_stm%ds0`”, where %d corresponds to the mode’s numeric ID. If you specify more than one connection, you must specify the same set of connections for each defined mode, each requiring a unique enable_code; specify the latter explicitly using “`-enable_code <binary>`” or allow it to be implicitly assigned by the tool (`-enable_code auto`).
- `-enable_code { binary_string | auto }`

An optional value that specifies a binary number (for example, “00110”) to be explicitly used to decode this mode using the specified enable_connections. By default or when the value “auto” is supplied, the tool automatically assigns a unique code to decode this mode based on the total number of scan modes. Each mode must have a unique code that uses all of the specified connections, or the tool reports an error.
- `-enable_dft_signal string`

An optional value that specifies the name of a dft scan mode signal as defined with the command “`get_dft_signal <name> -usage scan_mode`” to enable this mode. The tool uses the scan mode type associated with the dft signal if the `-type` option was not specified, or checked for compatibility otherwise.
- `-si_timing { leading_edge | trailing_edge | any_edge }`

An optional string and literal pair that provides the ability to control the capture edge of the first scan cell in a chain. The tool inserts a lockup (re-timing) cell between the scan chain input pin and the first scan cell in chain to control the capture edge of the first cell as leading or trailing edge. No lockup cell is inserted if “any_edge” is provided as the argument. The default edge type is “leading_edge”.
- `-so_timing { leading_edge | trailing_edge | any_edge }`

An optional string and literal pair that provides the ability to control the change edge of the last scan cell in a chain for this scan mode. The tool inserts a lockup (re-timing) cell between the scan chain output pin and the last scan cell in chain to control the change edge of the last cell as leading or trailing edge. No lockup cell is inserted if “any_edge” is provided as the argument. The default edge type is “trailing_edge”.

- `-edt_instances obj_spec`

An optional value that specifies EDT instances to connect the scan chains to. When the tool detects core descriptions for the specified instances, it automatically sets the `-si/so_connections` to the instance's scan pins.

When you use this option, the tool automatically infers the `-chain_count` value to be the number of available scan connection(s) on the specified EDT controller(s), and reports a message, as follows:

```
// command: add_scan_mode int_mode -type internal -si_pipelining off -edt_instance
// {test[0][0].my_white/point_scalar_mult_rtl_tessent_edt_lbist_c2_inst}
// Reading core description file ./tsdb_outdir/instruments/
point_scalar_mult_rtl_edt_lbist.instrument/
point_scalar_mult_rtl_tessent_edt_lbist_c2.tcd
// Setting the chain count to the number of specified scan connections (50).
// Automatically inferring '-enable_dft_signal int_mode' from the specified scan
// mode name.
```

This inferred mode `chain_count` now also accounts for the EDT scan connections from families included in the mode, as follows:

```
// Increasing the chain count to 140 in order to account for chain family EDT scan
// connections (90)
```

- `-ssh_instance obj_spec [-ssh_chain_groups ssh_chain_group_list]`

Optional string and literal pair that enables you to identify a single ScanHost node instance for the `add_scan_mode` command. When the tool detects a core description for the specified instance, it automatically sets the `-si/so_connections` to the scan pins of the instance. Use this option when you want to create uncompressed scan chains and have them driven directly by the SSH. If you are creating compressed scan chains, connect them to the EDT instance using the `-edt_instances` switch and not directly to the SSH.

`-ssh_chain_groups ssh_chain_group_list` — specify one or more subsets of the ScanHost connections using the SSH chain group ID(s). All ScanHost connections are selected when no SSH chain group ID is specified. When there is more than one ChainGroup associated with an SSH, include all the ChainGroups to be included in the scan mode.

- `-si_connections obj_spec -so_connections obj_spec`

Optional string and literal pairs that specify SI/SO connections to existing pins or ports to be used first when connecting newly allocated scan chains. The specified values can be a Tcl list of one or more port/pin names, a collection of one or more pin/port objects, or a port/pin Verilog name (of a certain width). They may be existing top-level input port(s) for `-si_connections` and existing top-level output port(s) for `-so_connections`, or alternatively `-si_connections` may correspond to existing output pin(s) and `-so_connections` to existing input pin(s). By default, `-chain_count` is implicitly set to the number of `si/so_connections` specified; if this is not the required behavior, then you should also set an explicit `-chain_count`.

- `-si_associated_ports obj_spec -so_associated_ports obj_spec`
Optional string and literal pairs that specify existing top-level port(s) associated to the internal connections identified using `-si/so_connections`. These are used in the `.tcd` file to describe the scan ports of the chains at the core boundary.
- `-si/so_port_format format`
An optional string that specifies the port format. The default `si/so_port_format` is set to `"ts_%s_si/so[%d]"` when there are more than one scan mode, otherwise it defaults to `"ts_si/so[%d]"`. The mode placeholder `"%s"` gets replaced by the chain mode name, whereas the index placeholder `"%d"` gets substituted by the chain index. A precision number may be used when specifying the index placeholder, for example the format `"lsi_si%2d"` would cause port names such as `"lsi_si00"`, `"lsi_si01"` to be created. Note that leading zeros are inserted automatically when needed making `"%2d"` implicitly equivalent to `"%02d"`.
- `-port_index_start_value integer`
An optional integer that specifies the starting port index. The starting index is 0 by default, but can be overridden by this option.
- `-port_scalar_index_modifier integer`
An optional switch and integer that specifies the increment used between each chain port indices. The default is 1.
- `-attribute_set_for_chain_assembly { attribute_list }`
An optional switch used to specify one or more string attributes to control scan chain assembly. When you use this switch and specify several string attributes, the tool creates clusters for every value combination of the specified attributes. For example, assume that you have defined the following quadrant and testpoint_type name attributes, and that all scan elements are attributed accordingly:

```
>register_attribute \  
-name quadrant \  
-value_type string \  
-object_types scan_element \  
-enum { NE NW SE SW }  
  
>register_attribute \  
-name testpoint_type \  
-value_type string \  
-object_types scan_element \  
-enum { control observation }
```

Scan elements that are not test points are not assigned a `"testpoint_type"` attribute value, whereas all scan elements are assigned a `"quadrant"` attribute value. This implies that each scan element has one of the following attribute value combinations:

Table 3-16. Attribute Value Combinations

"quadrant" attribute value	"testpoint_type" attribute value
NE	control

Table 3-16. Attribute Value Combinations (cont.)

“quadrant” attribute value	“testpoint_type” attribute value

SE	--
SW	control
SW	observation
SW	--

Accordingly, you can specify a mode that creates separate scan chains for each of the above 12 attribute value combinations as follows:

```
>add_scan_mode foo \  
-attribute_set_for_chain_assembly { quadrant testpoint_type }
```

- `-single_attribute_set_chains { on | off }`

An optional switch and literal pair that restricts a scan chain to a single set of attribute values. The default is on.

- `-single_class_chains { on | off }`

An optional switch and literal pair that controls whether to mix wrapper and non-wrapper cells in a single chain. The default is off, which means the tool distributes wrapper and internal cells onto the same chains.

- `-single_clock_domain_chains { on | off }`

An optional switch and literal pair that restricts a scan chain to a single clock domain. The default is off.

- `-single_clock_edge_chains { on | off }`

An optional switch and literal pair that restricts a scan chain with flops having a single edge. The default is off.

- `-single_power_domain_chains { on | off }`

An optional switch and literal pair that restricts a scan chain to a single power domain using the built-in attribute “power_domain_name”. The default is off. For attribute details, see the

table “Built in Attributes on Scan Element (SE) Object Type” in the [Scan Element Object Type](#) section of the *Tessent Shell Reference Manual*.

- `-single_cluster_chains { on | off }`

An optional switch and literal pair that restricts a scan chain to a single cluster using the built-in attribute “cluster_name”. The default is on. For usage examples, see [Scan Mode](#) and [Scan Insertion for Unwrapped Core](#) sections in the *Tessent Scan and ATPG User’s Manual*. For attribute details, see the table “Built in Attributes on Scan Element (SE) Object Type” in the [Scan Element Object Type](#) section of the *Tessent Shell Reference Manual*.

- `-single_wrapper_type_chains { on | off }`

An optional switch and literal pair that specifies that “-single_class_chains ON” controls whether to mix input wrapper and output wrapper cells in the same chain. The default is off.

- `-lockup_cell_type { latch | flop }`

An optional switch and string that controls the type of lockup (re-timing) cell to use between timing-constrained scan elements of new scan chains. The default cell type is latch.

- `-si_lockup_cell_type { latch | flop }`

An optional switch and string that controls the type of lockup (re-timing) cell to use between the scan chain input pin and the first scan cell. The default cell type is latch.

- `-so_lockup_cell_type { latch | flop }`

An optional switch and string that controls the type of lockup (re-timing) cell to use between the scan chain output pin and the last scan cell. The default cell type is latch.

Note

By default, the tool adds a pipeline flop in front of the wrapper chains to facilitate launching a transition from the first scan cells in the wrapper chains.

- `-unused_edt_pin_handling { auto | insert_pipelining_flop | tie_compactor_input }`

An optional switch that selects how to handle unused EDT chain pins. Options are:

`insert_pipelining_flop` — inserts scan chains composed of a single pipelining flop.

`tie_compactor_input` — ties-off the EDT compactor.

`auto` — selects “insert_pipelining_flop” for EDT controllers with bypass chains, and “tie_compactor_input” for all other EDT controllers. This is the default.

- `-si_pipelining { wrapper_chains_only | all_chains | off }`

An optional switch and string that controls whether the tool inserts a pipelining flop at the beginning of each chain if the first scan element of the chain does not have the attribute “no_si_pipelining” set and is not an OCC segment. When set to `all_chains`, all scan chains get a pipelining flop. When set to `wrapper_chains_only`, the tool only adds pipeline flops at the beginning of chains that begin with a wrapper flop in internal or external mode. The default is `wrapper_chains_only`.

Input wrapper cells and output wrapper cells are held in shift during internal test and external test respectively, while the internal flops are capturing normally and able to launch a transition (that is, no need for pipeline). Therefore, when you select the “wrapper_chains_only” option, the tool only adds pipeline flops at the beginning of chains that begin with a wrapper flop, such that a mixed internal chain (with core and wrapper elements) only gets a si_pipeline flop if its first element is a wrapper scan element.

- `-si_pipelining_type {non_scan_flop | holding_scan_flop}`

An optional switch and string that controls whether to implement pipelining using a simple non-scan data flop or a holding flop constructed using a scan flop with its output connected to its data input. The default is `holding_scan_flop`.

The requirement for the holding pipeline comes from LOS (Launch-Off-Shift) patterns generated by TestKompress. A pipeline flop is usually added at the beginning of every chain so that it can be used to launch a transition. When generating LOS patterns, if you add a pipeline flop, you can get coverage for the LOS patterns, but the first flop always captures an X, which impacts compression. This may not affect coverage but is likely to impact pattern count. The addition of hold flops instead of simple pipeline flops at the beginning of scan chains helps prevent this issue.

add_scan_segments

Context: dft -scan, dft -test_points -no_rtl

Mode: setup

Adds one or more existing scan segment(s).

Usage

add_scan_segments *scan_segment_name*

```
[ -no_trace ] [ -length integer ] [ -on_module obj_spec ]  
-si_connections obj_spec -so_connections obj_spec  
-clock_pins obj_spec [ -clock_update_edges { leading | trailing }... ]  
-scan_enable_pins obj_spec [ -scan_enable_inversion { false | true }... ]  
[ -set_pins obj_spec [ -set_inversion { false | true }... ] ]  
[ -reset_pins obj_spec [ -reset_inversion { false | true }... ] ]  
[ -ste_pins obj_spec [ -ste_inversion { false | true }... ] ]
```

Description

Use this command to add one or more existing scan segment(s).

See [Pre-Existing Scan Segments](#) and [Scan Insertion for Wrapped Core](#) in the *Tessent Scan and ATPG User's Manual* for usage examples.

Arguments

- ***scan_segment_name***
A required string that specifies the name of a scan segment.
- **-no_trace**
An optional switch that specifies to skip tracing even if a scan segment procedure file was read in; it can only be set if `-length` is specified. Defaults to OFF.
- **-length *integer***
An optional integer that specifies the length of the scan segment; a non-null value is required if `-no_trace` is used.
- **-on_module *obj_spec***
An optional switch and value pair that specifies an anchor module from which port specifications are relative to. Defaults to the top module.
- **-si/so_connections *obj_spec***
A required switch and value pair that specifies connections to existing SI/SO pins or ports. The specified value can be a Tcl list of one or more port/pin names, a collection of one or more pin/port objects, or a port/pin Verilog name (of a certain width). The specified values corresponds to existing top-level input port(s) or output pin(s) for `-si_connections` and existing top-level output port(s) or input pin(s) for `-so_connections`.

- **-clock_pinsobj_spec**
A required switch and value pair that specifies a collection of list of pins. Once provided, the tool can perform S rule checks for the clocks from the scan segment boundary. The first and the last elements of the collection correspond to the clocks for the first and last scan cells of a scan segment. The intermediate elements correspond to the clocks for the remaining scan cells in the scan segment. If there is just one element, then the tool assumes that the scan segment is using one clock.
- **-clock_update_edges { leading | trailing }...**
A repeatable switch and literal pair that specifies a list of clock edges at which the scan cells are capturing or the output is changing (for example, LE or TE). It is a list of edges. The first and the last elements of the list correspond to the edges for the first and the last scan cells in a sub-chain. There is a no need to have more than two elements in the list. If there are more than two elements, the tool ignores them. If there is only one element, then the tool assumes the first and last scan cells to change at the same edge.
- **-scan_enable_pins obj_spec**
A required switch and value pair that specifies a collection or list of scan_en pins driving the scan segment.
- **-scan_enable_inversion { false | true }**
An optional switch and literal pair that specifies whether there is inversion in the scan_en pin between the cell and the segment container. It is a list of boolean values.
- **-set_pins obj_spec**
An optional switch and value pair that specifies a collection or list of set pins for the scan cells in an existing segment.
- **-set_inversion { false | true }**
An optional switch and literal pair that specifies whether it is an active high or low set pin. The argument returns a list of Boolean values. The number of elements should match the collection size of set pins.
- **-reset_pins obj_spec**
An optional switch and value pair that specifies a collection or list of reset pins for the scan cells in an existing segment.
- **-reset_inversion { false | true }**
An optional switch and literal pair that specifies whether it is an active high or low set pin. The argument returns a list of Boolean values. The number of elements should match the collection size of set pins.
- **-ste_pins obj_spec**
An optional switch and value pair that specifies a collection or list of scan test enable pins driving the scan segment.

add_scan_segments

- -ste_inversion { false | true }

An optional switch and literal pair that specifies whether it is an active high or active low scan test enable pin. The argument returns a list of Boolean values. The number of elements should match the collection size of set pins. The default is false.

add_schematic_callout

Context: all contexts

Mode: all modes

Add an informational callout to a Tessent Visualizer schematic window.

Usage

```
add_schematic_callout object_spec -message string [-collapsed] [-display window_name]
```

Description

Adds informational callouts with the specified message string to objects in a Tessent Visualizer schematic window.

The string can contain “\n” to break the message into multiple lines.

Arguments

- ***object_spec***
A Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, gate_pin, instance, or net objects.
- **-message string**
A required string that specifies the message to be displayed in the callout. The string supports the use of the newline character sequence “\n” to break the message into multiple lines.
- **-collapsed**
Add the callouts as collapsed. If the mouse pointer is hovered over the callout, a tooltip with the callout message is displayed.
- **-display *window_name***
An optional switch and literal that specifies the Tessent Visualizer schematic window in which to display the callout. The valid options for the *window_name* argument are as follows:
 - flat_schematic** — A literal that specifies the Flat Schematic window.
 - hierarchical_schematic** — A literal that specifies the Hierarchical Schematic window.By default, the callout is added to the Flat Schematic window.

Examples

Example 1

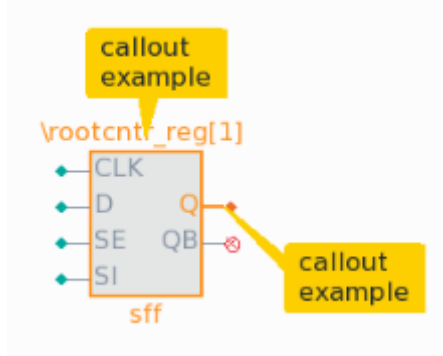

This example shows how to add a callout with the message:

```
callout
example
```

to a gate and a pin in the Hierarchical Schematic window:

```
add_schematic_callout { U_0/CSEEBlk/rootcncr_reg[1] U_0/CSEEBlk/rootcncr_reg[1]/Q } \  
-message "callout\nexample" -display hierarchical_window
```

Figure 3-24. Schematic Callouts

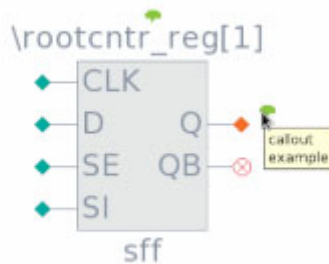

Example 2

This example shows the callouts from Example 1 added as collapsed.

```
add_schematic_callout { U_0/CSEEBlk/rootcncr_reg[1] U_0/CSEEBlk/rootcncr_reg[1]/Q } \  
-message "callout\nexample" -collapsed -display hierarchical_window
```

Figure 3-25. Schematic Callouts (Collapsed)

add_schematic_connections

Context: all contexts

Mode: setup, analysis

Displays design objects in the Tessent Visualizer schematic window and enables you to trace visually through the design.

Usage

```
add_schematic_connections object_spec {-to object_spec  
  | -forward {decision_point | end_point}  
  | -backward {decision_point | end_point}}  
  [-display {flat_schematic | hierarchical_schematic}]  
  [-distance_limit distance]  
  [-connections_limit max]  
  [-highlight color]
```

Description

Displays design objects in the Tessent Visualizer Flat or Hierarchical Schematic window and enables you to trace visually through the design.

Arguments

- *object_spec*
A Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, gate_pin, or net objects. This is the tracer starting point.
- -to *object_spec*
An optional Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, gate_pin, or net objects. This is the tracer target point when the tracer needs to find connectivity between pairs of design pins. The -to option is mutually exclusive to the -forward and -backward options.
- -forward {decision_point | end_point}
Trace forward from the starting pin(s) using the chosen strategy. The -forward option is mutually exclusive to the -to and -backward options.
- -backward {decision_point | end_point}
Trace backward from the starting pin(s) using the chosen strategy. The -backward option is mutually exclusive to the -to and -forward options.
- -distance_limit **int**
The threshold on hierarchy levels for tracing in the hierarchical schematic window (default: 100)
- -connections_limit **int**
The maximum number of connections to display (default: 100)

- -highlight *color*
One of none, green, blue, orange, yellow, red, pink, turquoise, or brown. “none” means to reset to the default color.
- -display *window_name*
An optional switch and literal that specifies the Tessent Visualizer schematic window in which to perform the tracing. The valid options for the *window_name* argument are as follows:
 - flat_schematic — A literal that specifies the Flat Schematic window.
 - hierarchical_schematic — A literal that specifies the Hierarchical Schematic window.By default, the callout is added to the Flat Schematic window.

Examples

This example shows how to trace forward from a pin to the path’s end point and highlight the nets on that path in red:

```
add_schematic_connections U_0/CSEEBlock/rootcntr_reg[1]/Q -forward end_point \  
-highlight red
```

add_schematic_objects

Context: all contexts

Mode: all modes

Displays provided objects in the specified Tessent Visualizer schematic window.

Usage

```
add_schematic_objects object_spec [-display {flat_schematic | hierarchical_schematic}] \  
[-highlight color]
```

Description

Displays provided objects in the specified schematic window, optionally highlighting them with one of the predefined colors. The command behavior for multiple objects is equivalent to issuing subsequent commands for each object, for example:

```
add_schematic_objects {a b c} -display flat_schematic
```

is equivalent to:

```
add_schematic_objects a -display flat_schematic  
add_schematic_objects b -display flat_schematic  
add_schematic_objects c -display flat_schematic
```

If the provided object is defined in the context of the flat model and the `-display` option is set to Hierarchical Schematic, an automated translation is applied if possible. If the object arrives from the hierarchical model and is to be displayed in the Flat Schematic window, an automated translation is applied if possible.

Arguments

- ***object_spec***

A Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, gate_pin, instance, or net objects.

- **`-display` *window_name***

An optional switch and literal that specifies the Tessent Visualizer schematic window in which to display the object. The valid options for the *window_name* argument are as follows:

`flat_schematic` — A literal that specifies the Flat Schematic window.

`hierarchical_schematic` — A literal that specifies the Hierarchical Schematic window.

By default, the object is added to the Flat Schematic window.

- **`-highlight` *color***

One of none, green, blue, orange, yellow, red, pink, turquoise, or brown. “none” means to reset to the default color.

Examples

```
add_schematic_objects { bsr_i1 bsr_i2 } -display hierarchical_schematic
```

add_schematic_path

Context: all contexts

Mode: all modes

Display the specified path in one of the Tessent Visualizer schematic windows.

Usage

```
add_schematic_path object_spec -direction {forward | backward} [-display window_name]  
[-highlight color]
```

Description

Displays the specified path in the Tessent Visualizer Flat or Hierarchical Schematic window.

Arguments

- ***object_spec***
A Tcl list or Tcl collection of one or more names of pin or gate_pin objects. Given lists of pins must represent existing connections in the hierarchical or flat data model.
- **-direction {*forward* | *backward*}**
A required switch and literal pair that specifies the direction of the path provided in *object_spec*.
- **-display *window_name***
An optional switch and literal that specifies the Tessent Visualizer schematic window in which to display the path. The valid options for the *window_name* argument are as follows:
 - flat_schematic** — A literal that specifies the Flat Schematic window.
 - hierarchical_schematic** — A literal that specifies the Hierarchical Schematic window.By default, the path is added to the Flat Schematic window.
- **-highlight *color***
One of none, green, blue, orange, yellow, red, pink, turquoise, or brown. “none” means to reset to the default color.

Examples

Example 1

This example shows how to add a path to the Flat Schematic window and highlight it with the default color:

```
add_schematic_path { U_0/CSEBlock/rootcntr_reg[1]/Q U_0/CSEBlock/U50/A0 } \  
-direction forward
```

Example 2

This example shows how to add two paths to the Hierarchical Schematic window and highlight them in yellow:

```
add_schematic_path { U_0/CSEEBlock/rootcntr_reg[1]/Q \  
U_0/CSEEBlock/U50/A0 U_0/CSEEBlock/U50/Y U_0/CSEEBlock/U49/A1 } \  
-direction forward -display hierarchical_window -highlight yellow
```

add_simdut_fault

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Injects a stuck-at-0 fault or a stuck-at-1 fault into the specified signal for SimDUT simulation.

Usage

```
add_simdut_fault -signal signal_name -fault [0 | 1]
```

Description

SimDUT uses the Verilog simulation capabilities to force the signal to 0 or 1. The Verilog capability has the following behavior: When you specify a pin pathname for the fault you want to inject, Verilog forces the associated signal to the specified value.

When you inject a fault at a specific pin pathname, SimDUT actually injects the fault at the whole net, not only on the specific pin. The fault acts like a fault injected on the upstream driver pin of the associated net. If you specify the input port of a cell and this port is attached to a net with fanout, then the fault acts like a fault injected on the driver port of that net.

When you run a test, SimDUT simulates the injected fault as if it were an actual defect in silicon, collects the simulated failing cycles, and returns the results.

You can run this command multiple times. When you specify a particular signal more than once, the last command that specifies the signal overrides all previous specifications. For example, if you first add a stuck-at-0 fault to signal A and later add a stuck-at-1 to signal A, SimDUT only adds the stuck-at-1 fault to signal A.

Arguments

- **-signal** *signal_name*

A required switch and string pair that specifies the name of a signal from the Verilog netlist. Refer to “[SimDUT Signal Naming Convention](#)” in *Tessent SiliconInsight User’s Manual for Tessent Shell* for more information

- **-fault** [0 | 1]

A required switch and literal that specifies the fault type as follows:

0 - Specifies stuck-at fault type SA0.

1 - Specifies stuck-at fault type SA1.

Examples

The following example injects an SA0 fault into the SIMDUT_TB.DUT_inst.memory00.q_a signal.

```
add_simdut_fault -signal SIMDUT_TB.DUT_inst.memory00.q_a -fault 0
```

add_simulation_context

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist.

Creates a new user-defined simulation context.

Usage

```
add_simulation_context context_name [-copy_from source_context_name] [-silent]
```

Description

The `add_simulation_context` command enables you to create a new user-defined simulation context in which the tool can perform simulation and introspection. Initially, the tool propagates tied values, such as power and ground, and then sets the remaining simulation values to X. The command automatically sets the new simulation context to be the current simulation context.

Arguments

- ***context_name***

A required string that specifies the name of the context. The ***context_name*** has to be different than one of the predefined context names listed in [Table 6-8](#) on page 2291.

- **-copy_from *source_context_name***

An optional switch and string that creates a new simulation context by copying an existing simulation context. Using this switch, you can bypass the initialization work done by the tool and build up a new simulation context. See “[Example 3](#)” on page 376.

- **-silent**

An optional switch that turns off the display of the message:

```
// 'sim_x' is the current simulation context.
```

Examples

Example 1

The following example shows how to create a new simulation context:

```
SETUP> add_simulation_context myContext
```

```
// 'myContext' is the current simulation context.
```

```
SETUP> get_simulation_context_list -user_defined
```

```
{myContext}
```

Example 2

The following example shows creates a new simulation context by generating an empty simulation context and subsequently copying another simulation context:

```
add_simulation_context $context  
copy_simulation_context -from $other_context  
set_current_simulation_context $context
```

Example 3

The following example illustrates using the `-copy_from` switch to create a new simulation context by copying an existing simulation context:

```
add_simulation_context $context -copy_from $other_context  
set_current_simulation_context $context
```

add_simulation_forces

Context: dft, patterns

Mode: setup, analysis

Prerequisite: The flat model must already exist.

Forces one or more *gate_pin* objects to the specified value(s).

Usage

```
add_simulation_forces obj_spec -values values
```

Description

The `add_simulation_forces` command forces the specified *gate_pin* object(s) to the specified force value(s) within the current simulation context. The actual simulation is not triggered until you issue the `simulate_forces` or `simulate_clock_pulses` command. If a specified *gate_pin* object has already been forced by an earlier `add_simulation_forces` command, and the tool has not yet simulated the previous force, the new force value overwrites the existing one in case of a conflicting value. Note that adding a simulation force also updates the *gate_pin* attribute named `simulation_value`.

This command is permitted only for user-defined simulation contexts.

Arguments

- ***obj_spec***
A required value that specifies one or more *gate_pin* objects.
- **-values *values***
A required switch and list of values, which specifies the force value applied to the specified *gate_pin* objects. *values* can be a Tcl list of values or a string of values.
The number of *values* must be one or must match the number of specified *gate_pin* objects. Valid values are: X, 0, 1, Z.
If only one value is specified, then the tool applies this value to all gates in the *gate_pin* collection.

Examples

The following example shows the effect of adding a force on a particular *gate_pin* object, and then triggering the tool to simulate that force:

```
ANALYSIS> set_current_simulation_context myContext
ANALYSIS> add_simulation_forces [get_gate_pins I1] -value 1
ANALYSIS> report_simulation_forces
```

Value	Object
1	I1

```
ANALYSIS> get_simulation_value_list [get_gate_pins I1]
```

```
{ x }
```

```
ANALYSIS> simulate_forces
```

```
ANALYSIS> get_simulation_value_list [get_gate_pins I1]
```

```
{ 1 }
```

add_synchronous_clock_group

Context: dft, dft -scan, dft -test_points, patterns

Mode: setup

Defines a set of clocks that are synchronous (compatible) with each other.

Usage

```
add_synchronous_clock_group {object_spec | -all} [-scope {capture | shift | all}]
```

Note

 Synchronous clock groups have no impact on scan chain analysis, scan insertion, test point identification, and EDT IP insertion (in the dft -test_points and dft -edt sub-contexts).

Description

You can define the set for shift, for capture, or for both. Clocks defined as synchronous during shift affect lockup latch insertion. Clocks defined as synchronous during capture primarily impact test point clock selection.

The add_synchronous_clock_group command can define specified interacting clocks as synchronous during capture cycles (that is, there is no clock skew between them). By specifying synchronous clocks explicitly, ATPG is permitted to pulse them at the same time to potentially reduce the generated test set size and improve test coverage.

The add_synchronous_clock_group command can also define a group of balanced clocks as synchronous during shift and load_unload cycles. This prevents DRC from issuing violations that apply to different shift clocks for elements that are clocked by the balanced clocks (for example, [T24](#)).

You can use “add_synchronous_clock_group -scope shift -all” to avoid inserting lockup cells between synchronous clock groups. This also permits the tool to create LE->TE chains.

Note

 Simulation mismatch errors are likely if you erroneously define clocks as synchronous that are not.

During MemoryBIST insertion, compatible memories including multi-port memories, can be assigned to the same memory controller. From a clocking perspective, memories are compatible when:

- All memory clock pins are connected to the same clock label.

OR

- Memory clock pins are connected to different clock labels, but are assigned to the same synchronous clock group and have the same frequency.

Compatible memories can be assigned to the same controller as long as all partitioning rules are met. If memories are assigned to a different controller, it can be for reasons other than their clock source.

Arguments

- ***object_spec***
A Tcl list or collection of pin or net objects.
- **-all**
A switch that specifies all defined clocks.
- **-scope {capture | shift | all}**
An optional argument and literal pair that specifies whether the clock groups are defined for capture, for shift, or for both. By default, groups are defined only for capture.

Examples

The following example creates clock groups from different sets of compatible clocks:

```
SETUP> report_clocks
```

```
User-defined Clocks (4):
```

```
=====
```

```
Sync and Async Source Clocks
```

```
=====
```

Name	Off State	Constraints	Internal
I1	0		No
I2	0		No
I3	0		No
I4	0		No

```
SETUP> add_synchronous_clock_group {I1 I2}
```

```
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Group
```

```
=====
```

```
// No.  Clocks (Labels)  Scope  
// ---  -  
// 1    I1                capture  
//      I2
```

```
SETUP> add_synchronous_clock_group {I3 I4}
```

```
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Groups
=====
// No.  Clocks (Labels)  Scope
// ---  -
// 1    I1                capture
//      I2
// 2    I3                capture
//      I4
```

```
SETUP> add_synchronous_clock_group -scope shift {I1 I2}
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Groups
=====
// No.  Clocks (Labels)  Scope
// ---  -
// 1    I1                capture
//      I2
// 2    I3                capture
//      I4
// ---  -
// 1    I1                shift
//      I2
```

Note

 For the following command, the capture clock group already exists. Therefore, the shift clock group is not created when it is specified with “-scope all”.

```
SETUP> add_synchronous_clock_group -scope all {I3 I4}
```

```
// Error: This user-defined synchronous clock group already exists in the
// scope of capture.
```

```
SETUP> report_synchronous_clock_groups

add_tied_signals

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Adds a value to floating signals or pins.

Usage

add_tied_signals {**0** | **1** | **X** | **Z**} *floating_object_name*... [-Pin]

Description

The add_tied_signals command assigns a specific value to not-clearly-defined floating signals or pins. If there are floating signals or pins in the design, a warning displays when you leave the setup mode. If you do not assign a specific value, the tool ties the signal or pin values to the default value. To change the default tied value, use the set_tied_signals command.

When you add_tied_signals or pins, the tool places them into the user class. When the netlist ties signals or pins to a value, the tool places them into the system class.

Note

 The tool does not tie a signal that is connected to bidirectional pins. For example, with a Verilog netlist that has a top level pin named Vdd of type “inout”, you cannot use “add_tied_signals 1 Vdd -pin” to tie Vdd high.

Arguments

- **0**
A literal that ties the floating nets or pins to logic 0 (low to ground).
- **1**
A literal that ties the floating nets or pins to logic 1 (high to voltage source).
- **X**
A literal that ties the floating nets or pins to unknown.
- **Z**
A literal that ties the floating nets or pins to high-impedance.
- *floating_object_name*
A required, repeatable string that specifies the floating nets or pins to which you want to assign a specific value. The tool assigns the tied value to all floating nets or pins in all modules that have the names you specify.

For pin names, you must include the -Pin switch on the command line; otherwise, the tool assumes the name is a net name.

add_tied_signals

- -Pin

An optional switch specifying that the *floating_object_name* argument that you provide is a floating pin name.

Examples

The following example ties all floating signals in the circuit that have the net names vcc and vdd, to logic 1 (tied to high):

```
add_tied_signals 1 vcc vdd
```

add_to_collection

Context: unspecified, all contexts

Mode: all modes

Adds objects to a base collection and returns the new collection without affecting the original base collection.

Usage

```
add_to_collection base_collection object_spec [-unique]
```

Description

By default, objects that exist in both the *base_collection* and the *object_spec* are duplicated in the resulting collection. You can use the `-unique` switch to remove duplicates.

Arguments

- *base_collection*
A required value that specifies the base collection to which objects are to be added. This base collection is copied to a new collection, and objects matching *object_spec* are added to the new collection. The *base_collection* can be an empty collection (empty string).
- *object_spec*
A required value that specifies a Tcl list of one or more object names, or a collection of one or more objects to add to the *base_collection*. The *object_spec* can be an empty collection (empty string). If *object_spec* is empty, the result is a copy of the base collection.
- `-unique`
An optional switch that removes duplicate objects from the resulting collection. By default, duplicate objects are not removed.

Examples

Example 1

The following example adds two collections, `a` and `b`, to create a new collection called `sum`.

```
set a [get_ports a*]  
set b [get_ports b*]  
set sum [add_to_collection $a $b]
```

Example 2

The following example creates a collection of all nets connected to pins of design instances matching `u1/myPrefix*`. Note that using the `-unique` option automatically removes duplicate nets.

add_to_collection

```
set sum ""
foreach_in_collection inst [get_instances u1/myPrefix* -of_type design] {
    set inputs [get_pins -of_instance $inst -direction input]
    set outputs [get_pins -of_instance $inst -direction output]
    set sum [add_to_collection $sum [get_fanins $inputs -stop_on net] -unique]
    set sum [add_to_collection $sum [get_fanouts $outputs -stop_on net] -unique]
}
```

Note

 This example could have used the [append_to_collection](#) command instead, which would have been more efficient because in this example, the intermediate collections are destroyed as soon as they are added.

add_wave_generator_pins

Context: all

Mode: all

Displays provided pin objects in the Tessent Visualizer Wave Generator tab.

Usage

add_wave_generator_pins *object_spec*

Description

A flat model must be available in order to use this command. If Tessent Visualizer is not started, the command automatically starts both server and client and opens the Wave Generator tab.

Arguments

- *object_spec*

A Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, or gate_pin objects.

Examples

```
add_wave_generator_pins {inst/clk inst/scan_en}
```

add_write_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Specifies the off-state value for specified RAM write control lines.

Usage

`add_write_controls {0 | 1} pin_pathname...`

Description

The `add_write_controls` command defines the circuit write control lines and assigns their off-state values. The off-state value of the pins or ports that you specify must be sufficient to keep the RAM outputs stable. The following are considerations for using this command:

- When the write control is already added as a clock, there is no need to also use `add_write_controls` for that port. This is the typical case, which means that for most usage it is unnecessary to explicitly use the `add_write_controls` command.
- If you want to have NR (non-clock) timing for write control lines that drive level-sensitive RAMs, you must add the write control using the `add_write_control` command; otherwise, the write control cannot pass DRC. NR timing for write control is not common.
- If a port drives the clock port of an edge-triggered RAM, the tool automatically infers that the port is a clock and adds it to the clock list. This is regardless of whether you added the port as a read control or not. For clocks that the tool infers, you must ensure that your timeplate includes the waveform for the newly defined clock.

Arguments

- **0 | 1**
A required literal that specifies 0 or 1 as the off-state value for the RAM write control lines.
- ***pin_pathname***
A required, repeatable string specifying the pins that are write control lines for the RAM and to which you want to assign an off-state value.

Examples

The following example assigns an off-state to two write control lines, w1 and w2:

```
add_write_controls 0 w1 w2
set_system_mode analysis
create_patterns
```

analyze_atpg_constraints

Context: dft -edt, patterns -scan

Mode: analysis

Checks the ATPG constraints you created for their satisfiability or mutual exclusivity.

Usage

```
analyze_atpg_constraints {-AUto | -ALL| [{pin_pathname | gate_id# | function_name}...  
[-Satisfy | -Exclusive]]} [-Bus]
```

Description

If you issue the `analyze_atpg_constraints` command without any arguments, the default is `-All`. When the command finishes, the tool displays a message that indicates whether the analysis passed, failed, or aborted the ATPG constraint analysis.

Note

 With EDT on, Tessent TestKompress support of this command is limited: it does not tell you if a constraint cannot be satisfied with EDT compression. It may also falsely report a constraint can be satisfied.

Arguments

The following lists the three methods for naming the objects for which you want to analyze the constraints. You can use any number of the three argument choices, in any order.

If you only specify an object name when you issue this command, by default, the tool performs the satisfiability (`-Satisfy`) analysis.

- `-Auto`

An optional switch that automatically tries to locate the atpg constraint that cannot be satisfied. The analysis checks to see if any single constraint cannot be satisfied, then reports each constraint that cannot be satisfied (given the current abort limit and other restrictions). Sometimes, each constraint can be satisfied by itself, but some set of constraints cannot all be satisfied. In this case, `-Auto` switch proceeds to a second analysis where it adds atpg constraints to a set to create a minimal set that can't be satisfied.

- `-ALL`

An optional switch that specifies for the tools to perform the ATPG analysis simultaneously for all the current ATPG constraints. If you do not specify an object name, this is the command default.

- `pin_pathname`

A repeatable string that specifies the pathname to the pin on which you are analyzing the constraints.

- **gate_id#**
A repeatable integer that specifies the gate identification number of the gate on which you want to analyze the constraints.
- **function_name**
A repeatable string that specifies the name of a function you created with the `add_atpg_functions` command. If you generated the ATPG function with the `-Cell` option and added constraints with the `-Cell` option, then the tool also analyzes the constraints on all the cells affected by that ATPG function.
- **-Satisfy**
An optional switch that specifies for the ATPG process to attempt to create a pattern that satisfies the selected ATPG constraint. This is the default if you specify an object name without a switch. During the ATPG process, the test generator does not consider the effect of other ATPG constraints or bus contention prevention (unless you use the `-Bus` switch).
When the command finishes, the tools display a message that indicates whether the analysis passed (the ATPG process successfully generated a pattern), failed (the ATPG process could not find any possible pattern), or aborted (the ATPG process gave up on trying to find a successful pattern). If the analysis passes, the data that the tool simulated for the pattern is available in parallel pattern zero (0).
- **-Exclusive**
An optional switch that specifies for the ATPG process to attempt to create a pattern that sets the selected ATPG constraint at a value different from its constrained value. This test's intent is to ensure that such a pattern does not exist. During the ATPG process, the test generator does not consider the effect of other ATPG constraints or bus contention prevention (unless you use the `-Bus` switch).
When the command finishes, the tool displays a message that indicates whether the analysis passed (the ATPG process could not find any possible pattern), failed (the ATPG process found another possible pattern), or aborted (the ATPG process gave up on trying to find a successful pattern). If the analysis fails, the data that the tool simulated for the pattern is available in parallel pattern zero (0).
- **-Bus**
An optional switch that specifies for the tool to consider bus contention prevention during the ATPG process.

Examples

The following example creates an ATPG constraint and then checks for mutual exclusivity:

```
add_atpg_constraints 1 435  
analyze_atpg_constraints 435 -exclusive
```

```
// ATPG constraint 435=1 failed mutual exclusivity check (data  
// in parallel pattern 0).
```

Related Topics

[add_atpg_constraints](#)

analyze_bus

Context: dft -edt, patterns -scan

Mode: analysis

Analyzes the specified bus gates for contention problems.

Usage

```
analyze_bus {gate_id#... [-Exclusivity | -Prevention | -Zstate]} |  
-Drc_check | -All | -Auto | -ANalyze_sequentially
```

Description

If the bus passes the analysis, the tool displays a message indicating that it did so. If the analysis aborts, the tool displays a message that identifies the tri-state drivers (TSDs) the tool was analyzing at abort time. If the bus fails the analysis, the tool displays a message that identifies the two offending TSDs (the tri-state drivers capable of being on simultaneously, while driving different values).

Note

 After using the `analyze_bus` command, the “`set_gate_report parallel_pattern 0`” command may display conflicting values if failures are found. That is, it is possible to have TIE-X gates with a 1/0 as an output. This is due to the `analyze_bus` command setting values to determine contention states. This analysis continues until a conflict is found.

In the tool, `analyze_bus` only shows the values that were used by the ATPG, and which the command considers relevant to the bus conflict. As the purpose of the analysis is to determine TSD input combinations that result in bus conflicts, the command does not simulate the output values of the TSD.

Note

 With EDT on, Tessent TestKompress support of this command is limited: it does not tell you if a constraint cannot be satisfied with EDT compression. It may also falsely report a constraint can be satisfied.

The commands “`set_contention_check On -Atpg`” and “`set_iddq_checks -Bus`” both cause ATPG to ensure that every bus is contention free during deterministic test generation. Sometimes, this requirement cannot be met for many or all of the faults targeted by ATPG, preventing you from obtaining adequate fault coverage. When this happens, the `analyze_bus` command determines which bus or buses cannot be made contention free, so that you can investigate the circuit around this bus to find out what is preventing contention-free tests.

When you issue this command, you must either specify a `gate_id#` value or one of the global switches (-Drc_check or -All).

Arguments

- **gate_id# -Exclusivity | -Prevention | -Zstate**

A repeatable integer with an optional switch that specifies the identification number of the bus gate and the type of analysis you want the tool to perform.

The available switch choices are as follows:

-Exclusivity — An optional switch that specifies for the tool to analyze the bus gate to see if it has mutual exclusivity. Mutual exclusivity means that only one driver can simultaneously force a strong signal onto the bus. Exclusivity is the default behavior when you specify a *gate_id#* value without a corresponding switch.

-Prevention — An optional switch that specifies for the tool to analyze the bus gate for its ability to attain a state of non-contention.

-Zstate — An optional switch that specifies for the tool to analyze the bus gate for its ability to attain a high-impedance (Z) state.

- **-Drc_check**

A switch that specifies for the tool to run the design rule check process again to categorize all buses and display the results. This is useful if you are changing constraints or the abort limit in an attempt to pass bus checks rather than abort.

- **-ALI**

A switch that specifies for the tool to use the more extensive ATPG process to place all the fail and abort buses in a noncontentious state. The internal simulation data for this pattern is available in parallel pattern 0 of the gate report.

- **-AUto**

A switch that automatically tries to locate the bus that cannot be made contention free. The analysis checks to see if any single bus cannot be made contention free. Each bus that cannot be made contention free (given the current abort limit and other restrictions) is reported to the user. Sometimes, each bus can be satisfied by itself, but some set of buses cannot all be satisfied. In this case, -Auto switch proceeds to a second analysis where it creates a minimized set of buses that can't be satisfied. The final, reduced set of buses, which cannot all be made contention free, is reported.

- **-ANalyze_sequentially**

A switch that specifies to perform a sequential analysis to find bus contention problems. For each clock defined using the [add_clocks](#) command, the sequential analysis applies a 1-cycle test, then a 2-cycle test, and so on, up to the reporting depths for which the tests fail. It then analyzes and lists the specific buses causing the failures at those depths.

Note

The same sequential analysis is performed automatically by the [analyze_restrictions](#) command if that command finds bus contention is the problem preventing success.

Examples

Example 1

The following example analyzes a bus that failed the regular bus contention checking:

```
set_system_mode analysis  
analyze_bus 493
```

Example 2

The following example displays the current categorization of bus gates, and then performs the prevention check on a specific bus gate:

```
set_system_mode analysis  
analyze_bus -drc_check  
  
// ATPG bus checking results: pass=1, bidi=1, fail=0, abort=0,  
// CPU time=0.00.  
  
analyze_bus 495 -prevention  
  
// Controllability justification was successful (data accessible using  
// parallel_pattern 0).  
// Pattern type: Basic_scan
```

Example 3

The following example analyzes a bus that failed the regular bus contention checking. Notice the input values of gates 7 & 8 (the two TSDs) show that ATPG has correctly illustrated a conflict condition:

```
// Warning: BUS gate /Y (9) has possible contention on drivers 7 and 8.  
// (E10-1)  
  
analyze_bus 9  
  
// ATPG bus checking performed on /Y (9) for 2 bused TSDs.  
// Failure occurred while checking TSDs 7 and 8 (data in  
// parallel_pattern 0).  
  
set_gate_report parallel 0  
report_gates 9  
  
// /Y (9) BUS  
// "I0" I (X) 7-/tri01/Y  
// "I1" I (X) 8-/tri02/Y  
// "OUT" O (X) 10-/Y  
  
report_gates 7  
  
// tri01 (7) TSD  
// E I (1) 3-/E  
// "D" I (1) 5-  
// Y O (X) 9-  
  
report_gates 8
```

analyze_bus

```
// tri02 (8) TSD
//      E      I (1) 4-/E1
//      "D"    I (0) 6-
//      Y      O (X) 9-
```

analyze_compression

Prerequisites: Scan-inserted netlist

Context: dft (with no subcontext), dft -edt, patterns (with no subcontext), patterns -scan

Mode: analysis

Analyzes the compression for an application in two steps.

Usage

Determine maximum possible compression (maximum chain:channel ratio)

```
analyze_compression [-Preserve_faults_from_analysis]
  [-NO_EDT] [-NO_COMPACTor]
  [-OVerride_user_settings | -NO_AUto]
  [-COMpaction_effort {Low | High | Maximum | integer}] [-NO_Analyze]
  [-COVerage_effort {Low | High}]
  [-NO_REDundancy_analysis]
  [-NO_TERMINATE_ineffective_atpg]
  [-PATterns_per_pass integer]
```

Emulating a virtual single block EDT configuration

```
analyze_compression [-Preserve_faults_from_analysis]
  [-COMPACTor_type Xpress | Basic]
  [-ENABle_edt_power_controller [-MIN_Switching_threshold_percentage int]]
  [-SEParate_control_data_channels]
  [-Uncompressed_chains chain_names ...]
  [-NO_Keep_uncompressed_chains ]
  [-CHAINs N] [{-CHANNELs M} | [{-INPut_channels I} {-OUtput_channels O}]]
  [-NO_EDT] [-NO_COMPACTor]
  [-OVerride_user_settings | -NO_AUto]
  [-COMpaction_effort {Low | High | Maximum | integer}] [-NO_Analyze]
  [-COVerage_effort {Low | High}]
  [-NO_REDundancy_analysis]
  [-NO_TERMINATE_ineffective_atpg]
  [-PATterns_per_pass integer]
```

Emulating a virtual modular EDT configuration

```
analyze_compression [-Preserve_faults_from_analysis]
  [-COMPACTor_type Xpress | Basic]
  [-ENABle_edt_power_controller [-MIN_Switching_threshold_percentage int]]
  [-SEParate_control_data_channels]
  [-Uncompressed_chains chain_names ...]
  [-NO_Keep_uncompressed_chains ]
  [-REPORT_EDT_Pins]
  [-NO_EDT] [-NO_COMPACTor]
  {-Edt_block block1_name [-CHAINs int] [{-CHANNELs int} |
  [-INPut_channels int -OUtput_channels int]}}
```

```
[{-Edt_block block2_name [-CHAINS int] {[-CHANNELS int] |
  [-INPut_channels int -OUtput_channels int]} ...]
{[-Broadcast_all_channels_to_identical_blocks [{block1_name block2_name ...}]]} ...
{[-SHARE_data_channels [{block3_name block4_name ...}]
  [-DATA_and_control_channels [int]]}] ...
[-OVerride_user_settings | -NO_AUto]
[-COMpaction_effort {Low | High | Maximum | integer}] [-NO_Analyze]
[-COVerage_effort {Low | High}]
[-NO_REDundancy_analysis]
[-NO_TERMINATE_ineffective_atpg]
[-PATterns_per_pass integer]
```

Description

Analyzes the compression for an application in two steps. The two steps are as follows:

1. Analyzes a scan-inserted design and returns a range of maximum chain:channel ratios where the test coverage begins to decline.
2. Emulates a hardware configuration for a specified chain:channel ratio, generates temporary test patterns, and returns test data statistics for the compression configuration.

Note

 Before using the `analyze_compression` command, the target design should be setup for ATPG including the definition of any controls for internal clocks and the definition of all scan chains. In most cases, you can simply replace the `create_patterns` command in your dofile with the `analyze_compression` command and the switches you want. Detailed instructions on how to use the `analyze_compression` command to perform compression analysis are presented in the “[Analyzing Compression](#)” in the *Tessent TestKompress User’s Manual*.

The `analyze_compression` command uses the fault model type specified by the `set_fault_type` command. If no fault model type is specified, the tool uses the “stuck” fault model by default. The `analyze_compression` command uses the current fault population. If no faults are added, the tool operates on all faults or a subset of sampled faults that are determined by the fault sampling rate specified by the “`set_fault_sampling_rate`” command.

To enable N-detection during analysis, you must first issue the `set_multiple_detection` command. After enabling N-detection, you can run the `analyze_compression` command with the `-Preserve_faults_from_analysis` switch and the tool preserves the N-detection information for all the detected faults; if you do not specify the `-Preserve_faults_from_analysis` switch, the tool restores the N-detection information for all detected faults to the states prior to the execution of the `analyze_compression` command. For an example of enabling N-detection, see [Example 16](#).

Note

 During emulation, if the emulated EDT block has the same name as the original one, the tool preserves all the scan cells in the original EDT block; if you specify new EDT block names, the tool tries to allocate all scan cells into the new EDT blocks to get balanced scan chains. You cannot mix the names of the original EDT blocks with the names of the newly emulated EDT blocks. This is illustrated in [Example 17](#).

For more information, see “[Analyzing Compression](#)” in the *Tessent TestKompress User’s Manual*.

Note

 When you perform compression analysis, the final order of scan cells in each scan chain in the design is not known. The order of the scan cells used as deterministic bits in the test cube impacts ATPG results. If many of the deterministic bits are clustered in consecutive cycles, more EDT_ABORT faults may appear because the clustered deterministic bits may not be compressed. When this occurs, ATPG test coverage may drop.

During compression analysis, TestKompress assumes the scan chains are organized in a balanced way based on an existing scan cell ordering. However, in the real design, scan cells may be in an arbitrary position depending on which scan stitching tool was used. If the clustering of deterministic bits occurs during compression analysis but not in the real design or if the clustering occurs in the real design but not in compression analysis, a discrepancy in the ATPG results may occur.

Arguments

- -Preserve_faults_from_analysis

An optional switch that preserves the fault status at the end of the analyze_compression operation based on the ATPG run of the command even though no patterns are stored. By default, without the -Preserve_faults_from_analysis switch, the fault status at the end of the analyze_compression operation is returned to its status prior to the execution of the command. This switch can be used to experiment with analyzing faults remaining after an analysis run.

If the -Preserve_faults_from_analysis switch is specified, the tool preserves the N-detection information for all the detected faults during the analyze_compression operation.

Note

 When you specify this option, if there are already internal patterns generated by a previous create_patterns command, the tool deletes all internal patterns and issues a warning stating that the previously generated patterns are deleted because they are inconsistent with the fault population.

- -OVERRIDE_user_settings

For information about this switch, see the [create_patterns](#) command.

- **-NO_AUto**
For information about this switch, see the `create_patterns` command.
- **-Compaction_effort {Low | High | Maximum | integer}**
For information about this switch, see the `create_patterns` command.
- **-NO_Analyze**
For information about this switch, see the `create_patterns` command.
- **-COVerage_effort {Low | High}**
For information about this switch, see the `create_patterns` command.
- **-NO_REDundancy_analysis**
For information about this switch, see the `create_patterns` command.
- **-NO_TERMINATE_ineffective_atpg**
For information about this switch, see the `create_patterns` command.
- **-PATterns_per_pass integer**
For information about this switch, see the `create_patterns` command.
- **-COMPACTOR_type Xpress | Basic**
An optional switch that specifies the compactor to use for the analysis. By default, the Xpress compactor is used. The specified compactor is applied to all blocks in a block-level application. This switch cannot be specified more than once; otherwise, an error message is generated.
- **-ENable_edt_power_controller [-MIN_Switching_threshold_percentage *int*]**
An optional switch and switch-integer pair that enables emulation of the low-power controller and specifies the minimum switching threshold for the low-power controller being used for compression emulation. You must specify the `-Channel` option when using this option.

If this switch is specified, the tool uses the specified low-power controller for all blocks. If no low-power usage is specified, then no low-power is used. This switch cannot be specified more than once; otherwise, an error message is generated.

The behavior of the `analyze_compression` command, when used with this switch, can be effected by the switching threshold in several ways.
 - When using this switch, but the “`set_power_control shift`” command is not used, at the start of `analyze_compression`, the tool issues the following message:

```
// Note: Emulating low-power patterns with <N>% shift switching
// threshold.
// To use a different low power shift threshold or disable
// low power shift, use the 'set_power_control' command.
```

- When using this switch, and meanwhile the “set_power_control shift off” command is used, the tool does not emulate low-power patterns, even if specified with analyze_compression, the tool issues this message:

```
// Warning: Switching threshold for low power controller was
// specified but is ignored because 'set_power_control shift' is
// set to OFF.
// Emulating patterns without low power control.
```

- When using “-enable_edt_power_controller -min_switching_threshold_percentage X”, but meanwhile “set_power_control shift on Y is used, and $X < Y$, the tool uses the setting of the set_power_control command (Y% in this case) as opposed to the hardware setting with analyze_compression (X% in this case). No message is issued.
- If set_power_control is used, but switching threshold is not used with analyze_compression, the tool issues this message:

```
// Note: Switching threshold was set using 'set_power_control
// shift on -switching_threshold_percentage <int>' but is
// ignored because the -min_switching_threshold_percentage was
// not used with the analyze_compression command to specify the
// configuration of the low power controller. Emulating patterns
// without low power control.
```

- **-SEParate_control_data_channels**

An optional switch that, if used, tells the tool to separate control and data channels for all EDT blocks during emulation, regardless of whether channel sharing is used. If this switch is not used, the tool does not separate control and data channels for all EDT blocks unless the block is in a channel sharing group specified with the -SHARE_data_channels switch.

- **-Uncompressed_chains *chain_names* ...**

An optional switch and Tcl list of chain names that specifies uncompressed scan chains. You must define these chain names with the add_scan_chains command. If a chain name is not found, the tool issues an error on the first unfound chain name.

If EDT is ON, then the following applies:

- If you specify -Uncompressed_chains without specifying the optional -NO_Keep_uncompressed_chains, then the tool treats the specified uncompressed chains and the original uncompressed chains as uncompressed chains.
- If you specify -Uncompressed_chains with the optional -NO_Keep_uncompressed_chains, then the tool only treats the specified uncompressed chains as uncompressed chains.

If the current design has no EDT or EDT is OFF, then the following applies:

- If you specify -Uncompressed_chains, then the tool only treats the specified chains as uncompressed chains while using the scan cells in the remaining uncompressed chains for compression analysis.

- **-NO_Keep_uncompressed_chains (EDT ON only)**

An optional literal that instructs the tool not to treat any original uncompressed chains in the design as uncompressed unless they are specified in the `-Uncompressed_chains`.

By default if it is an EDT design, the tool keeps any uncompressed scan chains as uncompressed and does not merge those cells with the compressed chains. If this switch is used on a design that does not contain any uncompressed chains, then the tool issues a warning.

If the current design has no EDT or EDT is OFF, then this switch is ignored.

- **-REPORT_EDT_Pins**

An optional literal that instructs the tool to call the `“report_edt_pins -all -group_by_pin_name”` command at the end of the compression analysis operation. The tool reports example pin names, and provides one example on how top-level pins are connected with the EDT block channels so that channel sharing/broadcasting can be emulated.

- **-NO_EDT**

An optional switch that turns off EDT when running compression analysis. This can help you determine the baseline ATPG pattern count. You can use this in conjunction with the results of the `-no_compactor` switch to explore why EDT pattern count is higher than pattern count without EDT. This switch is not compatible with any switch that is related to EDT (such as `-compactor_type` or `-edt_block`). To emulate a design with the specified number of chains, use `“analyze_compression -chains <N> -no_edt”`.

- **-NO_COMPACTor**

An optional switch that turns off compactor emulation when running compression analysis. If the EDT pattern count is higher than the pattern count without EDT (generated with the `-no_edt` switch), it could be due to X values going into the compactor, encoding capacity, or both. Turning off compactor emulation enables you to evaluate the impact of X values going into the compactor. You can check the encoding capacity by specifying more input channels. This switch is incompatible with the `-compactor_type` and `“-output_channels <O>”` arguments; however, you can supply `“-input_channels <I>”` with `-no_compactor`.

- **{-Edt_block *block1_name*} ...**

An optional, repeatable, switch and string pair that specifies the name of a design block containing compression logic (compression block). This option specifies multiple compression blocks for the analysis of a block-level architecture design.

If you only specify one compression block, the design is treated as a chip-level architecture for analysis.

Chain or channel specifications must be defined for each block individually.

If you do not specify any compression blocks for a block-level design, the design is analyzed with the configurations defined in the design.

Only the associated scan cells are used to analyze existing compression blocks. If you do not specify any scan channels for existing blocks, the tool uses those specified in the design.

If you specify any new compression blocks, the tool completely ignores the scan chain and channel configurations defined in the design. For the analysis, the tool distributes the scan cells across all specified blocks in a way that balances the scan chain length for all blocks. In this case, you must specify both chains and channels for each block. You cannot define both new and existing compression blocks in one design.

- **-CHAINS** *int*

An optional switch and integer pair that specifies how many scan chains to use when emulating a chain:channel ratio for test data volume and fault coverage analysis. If no scan chains are specified, the scan chains defined in the design are used.

By default, using `-chains int` leads to reordering scan chains and scan cells to make the scan chains as balanced as possible. There is a way to skip the reordering.

- When you emulate a virtual single block EDT configuration:

If you do not use `-chains int`, the tool maintains the order of the scan chains and scan cells. For example the original design has 100 chains.

analyze_compression -channel 2

The tool emulates one EDT block with 2 channels and 100 chains without reordering the scan chains and scan cells.

- When you emulate a virtual modular EDT configuration:

If you do not use `-chains int` and use the original EDT block names, the tool maintains the order of the scan chains and scan cells. For example there are two blocks in the original design, blk1 (2 channels, 100 chains) and blk2 (2 channels, 200 chains).

analyze_compression -edt_block blk1 -channel 3 -edt_blk blk2 -channel 4

The tool emulates blk1 with 3 channels, 100 chains and blk2 with 4 channels, 200 chains, without reordering the scan chains and scan cells in each block.

- **[-CHANNELs int] | [{-INPut_channels int} {-OUtput_channels int}]**

An optional switch and integer pair or set of switch and integer pairs that specifies the channels to use when emulating a chain:channel ratio for test data volume and fault coverage analysis. Channels must be specified when analyzing a design without compression logic inserted.

If no channels are specified for a design with compression logic inserted, the following scenarios apply:

- **Block-Level Architecture** — The sum of the channels defined for each block is used, and the design is emulated as a single compression block.

- **Chip-Level Architecture** — The channels defined by the existing compression logic are used.

Use the `-input_channels/-output_channels` arguments to specify an asymmetrical channel configuration. These arguments must be used in pairs, except when you specify `-no_compactor`, in which case you can specify `-input_channels` without `-output_channels`. You can also optionally use `-no_compactor` with `-channels`.

- `{[-Broadcast_all_channels_to_identical_blocks [{block1_name block2_name ...}]]} ...`

An optional argument used to construct one or more groups of identical blocks that share input channels. The specified blocks must be pre-existing identical EDT blocks. The tool broadcasts the input channels to all EDT blocks that are in one specified identical block group.

If this argument is specified but no `block_name` parameters are specified, the tool assumes that all existing EDT blocks are identical; in this case, only one channel broadcasting group is permitted.

- `{[-SHARE_data_channels [{block3_name block4_name ...}] [-DATA_and_control_channels [int]]]} ...`

An optional argument used to construct one or more channel sharing groups such that the EDT blocks in each channel sharing group share data input channels with each block having individual control channels such that the total number of input channels used in this group equals the input channel number specified by `-DATA_and_control_channels`. The tool calculates the minimum number of input channels based on the channel sharing groups you define with this argument.

The `block_name` parameters are the names of the blocks defined to be in the channel sharing group.

The following rules apply to the creation of channel sharing groups:

- If no `block_name` parameters are specified, the design must already have two or more EDT blocks; otherwise, the tool generates an error.
- If no `block_name` parameters are specified, all blocks share the data channels; in this case, only one channel sharing group is permitted.
- If `block_name` parameters are specified, each channel sharing group must have a minimum of two blocks defined; otherwise, the tool generates an error.
- An EDT block can only be defined in one channel sharing group or one channel broadcasting group. Note, an EDT block does not have to be defined in any channel sharing or channel broadcasting group.
- If a block is defined in a channel sharing group, the “[set_edt_options -separate_control_data on](#)” switch is automatically set. In this case, the tool calculates the number of control channels that are needed for the block by determining the number of control bits and the length of data channels. The total input channel count for each block, specified by either the `analyze_compression`

“-channels” or “-input_channels” switches, must be greater than or equal to the number of control channels plus 1. This means the block must have at least one data channel.

- The specified input pin count (N) for each channel sharing group must be greater than or equal to the sum of the #control channels on each block in the group plus 1. That is, at least one pin must be shared by the data channels of the EDT blocks in one channel sharing group.
- The number of input data pins available to be shared in the group cannot be greater than or equal to the sum of all data channels of all blocks in the group.
- The number of input data pins available to be shared in this group must be greater than or equal to the maximum number of data input channels of all EDT blocks in the group.

Note

 The analyze_compression command supports channel sharing and channel broadcasting separately. You can use it to emulate a group of cores with channel sharing and a different group of identical cores with broadcasting, but there can not be any overlap of the cores between the groups.

As a workaround, use a representative core instance from each identical core group and perform channel sharing emulation. The results should be close to adding the other equivalent cores if each core is well isolated.

Examples

Example 1

The following example analyzes a design and returns the upper range of chain:channel ratios:

```
analyze_compression  
  
// For stuck-at faults  
//  
// Chain:Channel Ratio      Predicted Fault Coverage Drop  
// -----  
// 153                      negligible fault coverage drop  
// 154                      0.01 % - 0.05 % drop  
// 160                      0.10 %  
// 168                      0.15 %  
// 171                      0.20 %  
...  
// CPU time is 155 seconds.
```

Example 2

The following example emulates compression logic with 800 scan chains and 8 scan channels, generates test patterns, and displays test pattern statistics for a chip-level architecture:

```
set_fault_sampling 1  
analyze_compression -chains 800 -channels 8
```

//
```

Example 4

In the following example, a fault model type is not specified. By default, the stuck-at fault model type is used.

analyze_compression -chain 100 -channel 2

```
// *****  
// * Run ATPG for stuck-at faults.  
// *****
```

Example 5

In the following example, the `-Preserve_faults_from_analysis` switch is used to update the fault detection status based on the ATPG results of the `analyze_compression` command.

analyze_compression -chain 100 -channel 2 -preserve_faults_from_analysis

```
// *****  
// * Run ATPG for stuck-at faults.  
// *****
```

Note: Fault detection status will be updated based on the ATPG results of `analyze_compression` even though no patterns are stored.

Example 6

In the following example, the `set_fault_type` command is used to specify the fault model type to be used by the `analyze_compression` command.

**set_fault_type transition
analyze_compression -chain 100 -channel 2**

```
// *****  
// * Run ATPG for transition faults.  
// *****
```

Example 7

In the following example, the `set_fault_type` command is used to specify that a user-defined fault model type is to be used by the `analyze_compression` command.

**set_fault_type UDFM
read_fault_sites ../fault/sampled.udfm
analyze_compression -chain 100 -channel 2**

```
// *****  
// * Run ATPG for UDFM faults.  
// *****
```

Example 8

In the following example, the `Xpress` compactor type is specified for a single EDT block.

analyze_compression -compactor_type xpress -chain 100 -channel 2

Example 9

In the following example, both EDT blocks are emulated with the `Xpress` compactor.

**analyze_compression -compactor_type xpress \
-edt_block blk1 -chain 100 -channel 2 \
-edt_block blk2 -chain 200 -channel 2**

Example 10

In the following example, both EDT blocks are emulated with the Basic compactor.

```
analyze_compression \  
    -edt_block blk1 -compactor_type basic -chain 100 -channel 2 \  
    -edt_block blk2 -chain 200 -channel 2
```

Example 11

In the following example, only one EDT block is emulated with the low-power controller.

```
analyze_compression -enable_edt_power_controller \  
    -min_switching_threshold_percentage 20 \  
    -chain 100 -channel 2
```

Example 12

In the following example, the low-power controller is used for both EDT blocks. The `switching_threshold_percentage` switch is set to 20 percent.

```
analyze_compression -enable_edt_power_controller \  
    -min_switching_threshold_percentage 20 \  
    -edt_block blk1 -chain 100 -channel 2 \  
    -edt_block blk2 -chain 200 -channel 2
```

Example 13

In the following example, both EDT blocks are emulated with the same low-power controller.

```
analyze_compression -edt_block blk1 \  
    -enable_edt_power_controller \  
    -min_switching_threshold_percentage 20 -chain 100 -channel 2 \  
    -edt_block blk2 -chain 200 -channel 2
```

Example 14

In the following example, only one EDT block is emulated with the low-power controller. The `switching_threshold_percentage` switch is set to 15 percent by default.

```
analyze_compression -enable_edt_power_controller -chain 100 -channel 2
```

Example 15

In the following example, both EDT blocks are emulated with the low-power controller. The `switching_threshold_percentage` switch is set to 15 percent by default.

```
analyze_compression -enable_edt_power_controller \  
    -edt_block blk1 -chain 100 -channel 2 \  
    -edt_block blk2 -chain 200 -channel 2
```

Example 16

The following example enables N-detection ATPG during the `analyze_compression`.

```
set_multiple_detection -guaranteed_atpg_detections 3 -desired_atpg_detections 1  
set_fault_sampling 2  
analyze_compression -chain 100 -channel 2
```

```
// *****
// *   Run ATPG for stuck-at faults.
// *****

```

Example 17

The following examples demonstrate how the tool enforces the naming requirements for the emulation step.

Case 1

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block1 -chain10 -channel 1 \  
-edt_block block2 -chain10 -channel 1
```

The tool maintains all cells in the original block1 and block2 because they have the same name as the original, but changes the number of scan chains and channels based on the command.

Case 2

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block3 -chain10 -channel 1 \  
-edt_block block4 -chain10 -channel 1
```

The tool does not maintain all of the cells in the original blocks because the names changed. The tool reallocates cells to make all of the chains in the two blocks as balanced as possible.

Case 3

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block1 -chain10 -channel 1 \  
-edt_block block4 -chain10 -channel 1
```

The tool does not permit the mixing of the original names and the newly specified names and generates an error message.

Case 4

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block1 -chain10 -channel 1
```

The tool does not permit this case because it changes two blocks to one block, but still uses the same name as before.

Case 5

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block3 -chain10 -channel 1
```

The tool supports this case.

Case 6

The original design has one EDT block named block1.

```
analyze_compression -edt_block block1 -chain10 -channel 1 \  
-edt_block block2 -chain10 -channel 1
```

The tool does not permit this and displays an error message.

Case 7

The original design has one EDT block named block1.

```
analyze_compression -edt_block block2 -chain10 -channel 1 \  
-edt_block block3 -chain10 -channel 1
```

The tool supports this case.

Example 18

The following examples demonstrate how the tool supports channel sharing.

Case 1:

The design has one sharing group with 12 input channels shared between all blocks (block1, block2, block3 and block4).

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
-edt_block block2 -chain 200 -channel 4 \  
-edt_block block3 -chain 300 -channel 6 \  
-edt_block block4 -chain 200 -channel 2 \  
-share_data_channels -data_and_control_channels 12
```

Case 2:

The design has two sharing groups. The first group has 6 input channels shared between block1 and block2. The second group has 8 input channels shared between block3 and block4.

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
-edt_block block2 -chain 200 -channel 4 \  
-edt_block block3 -chain 300 -channel 6 \  
-edt_block block4 -chain 200 -channel 2 \  
-share_data_channels block1 block2 -data_and_control_channels 6 \  
-share_data_channels block3 block4 -data_and_control_channels 8
```

Case 3:

The design has one sharing group with 6 input channels shared between block1 and block2, but block3 does not share any inputs with other blocks.

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
-edt_block block2 -chain 200 -channel 4 \  
-edt_block block3 -chain 300 -channel 6 \  
-share_data_channels block1 block2 -data_and_control_channels 6
```

Case 4:

In this example, a block is included in multiple channel sharing groups:

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
                    -edt_block block2 -chain 200 -channel 4 \  
                    -edt_block block3 -chain 300 \  
                    -channel 6 -share_data_channels block1 block2 \  
                    -data_and_control_channels 6 \  
                    -share_data_channels block1 block3 -data_and_control_channels 8
```

The following error is generated:

```
// Error: Block 'block1' is included in multiple channel sharing groups.
```

Case 5:

In this example, a block is added to a channel sharing group but the block does not share input channels with any other blocks in that group.

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
                    -edt_block block2 -chain 200 -channel 4 \  
                    -edt_block block3 -chain 300 -channel 6 \  
                    -share_data_channels block1 -data_and_control_channels 6 \  
                    -share_data_channels block2 block3 -data_and_control_channels 8
```

The following error is generated:

```
// Error: Block 'block1' is specified inside a channel sharing group, but  
// does not share input channels with any other block.
```

Case 6:

In this example, a block is specified inside more than one channel sharing group.

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
                    -edt_block block2 -chain 200 -channel 4 \  
                    -edt_block block3 -chain 300 -channel 6 \  
                    -share_data_channels block1 block1 -data_and_control_channels 6 \  
                    -share_data_channels block2 block3 -data_and_control_channels 8
```

The following error is generated:

```
// Error: Block 'block1' is specified multiple times inside a channel  
// sharing group.
```

Case 7:

This example assumes that each block needs two control channels.

```
analyze_compression -edt_block block1 -chain 100 -channel 3 \  
                    -edt_block block2 -chain 200 -channel 4 \  
                    -edt_block block3 -chain 300 -channel 4 \  
                    -share_data_channels -data_and_control_channels 6
```

The following error is generated:

```
// Error: Channel sharing group with 'block1' (2 control channel),  
// 'block2' (2 control channel), and 'block3' (2 control channels) needs  
// at least 7 input channels for channel sharing.
```

Case 8:

This example assumes that block1 has one control and one data channel; block2 has one control channel and two data channels; and block3 has two control channels and two data channels. Because the command specifies to share nine channels, no channels are actually shared.

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
-edt_block block2 -chain 200 -channel 3 \  
-edt_block block3 -chain 300 -channel 4 \  
-share_data_channels -data_and_control_channels 9
```

The following error is generated:

```
// Error: Excessive input channels specified for channel sharing group  
// which includes 'block1'. This group requires between 6 and 8 input  
// channels.
```

Case 9:

This example assumes that block1 has one control and one data channel; block2 has one control channel and two data channels; and block3 has two control channels and two data channels. The command specifies to share five channels which is not enough.

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
-edt_block block2 -chain 200 -channel 3 \  
-edt_block block3 -chain 300 -channel 4 \  
-share_data_channels -data_and_control_channels 5
```

The following error is generated:

```
// Error: The available input channels (5) specified for the channel  
// sharing group is not enough to drive the data input channels for block  
// 'block2' and 'block3'. This group requires between 6 and 8 input  
// channels. Alternatively, if you want to keep the shared channel count  
// (5), you may reduce the number of input channels for the following  
// blocks:  
// 'block1' may have up to 2 channels.  
// 'block2' may have up to 2 channels.  
// 'block3' may have up to 3 channels.
```

Case 10:

In this example, channel sharing is specified but neither the total number of input pins nor any channel sharing groups are defined. In this case, the tool defines the channel sharing group to be all EDT blocks and calculates the required number of input channels for those three blocks.

```
analyze_compression -share_data_channels
```

The following message is generated:

```
// Sharing 8 input channels across block1 block2 block3.
```

Case 11:

In this example, channel sharing is specified and two channel sharing groups are defined. However, the total number of input pins is not specified. In this case, the tool calculates the required number of input channels for each of the two defined channel sharing groups.

```
analyze_compression -edt_block block1 -chain 100 -channel 2 \  
-edt_block block2 -chain 200 -channel 4 \  
-edt_block block3 -chain 300 -channel 6 \  
-edt_block block4 -chain 200 -channel 2 \  
-share_data_channels block1 block2 \  
-share_data_channels block3 block4  
  
// Sharing 8 input channels across block1, block2.  
// Sharing 10 input channels across block3, block4.
```

Example 19

The following examples demonstrate how the tool supports broadcasting channel input to blocks defined to be identical.

Case 1:

In this example, the original design is assumed to have three identical EDT blocks and each block has eight EDT input channels. Because no block names are listed, the tool assumes all EDT blocks are identical and broadcasts to all three blocks.

```
analyze_compression -broadcast_all_channels_to_identical_blocks  
  
// Broadcasting 8 input channels to block1, block2, block3.
```

Case 2:

In this example, the tool broadcasts to two specified identical blocks and shares channels between two specified non-identical blocks.

```
analyze_compression -edt_block block1 -chain 100 -channel 4 \  
-edt_block block2 -chain 100 -channel 4 \  
-edt_block block3 -chain 300 -channel 6 \  
-edt_block block4 -chain 200 -channel 2 \  
-broadcast_all_channels_to_identical_blocks block1 block2\  
-share_data_channels block3 block4 -data_and_control_channels 10  
  
// Broadcasting 4 input channels to block1, block2.  
// Sharing 10 input channels across block3, block4.
```

Case 3:

In this example, the tool broadcasts channel inputs to two different groups of identical blocks.

```
analyze_compression -edt_block block1 -chain 100 -channel 4 \  
-edt_block block2 -chain 100 -channel 4 \  
-edt_block block3 -chain 300 -channel 6 \  
-edt_block block4 -chain 200 -channel 6 \  
-broadcast_all_channels_to_identical_blocks block1 block2 \  
-broadcast_all_channels_to_identical_blocks block3 block4  
  
// Broadcasting 4 input channels to block1, block2.  
// Broadcasting 6 input channels to block3, block4.
```

Case 4:

In this example, the tool attempts to broadcast channel inputs to two identical blocks; an error is generated because blocks that were specified to be identical are not identical because they have a different number of input channels.

```
analyze_compression -edt_block block1 -chain 100 -input_channels 3 -output_channels 2 \  
-edt_block block2 -chain 100 -input_channels 4 -output_channels 2 \  
-broadcast_all_channels_to_identical_blocks block1 block2  
  
// Error: EDT block 'block1' and 'block2' are non-identical due to  
// different number of input channels.  
// '-broadcast_all_channels_to_identical_blocks' is not allowed.
```

Case 5:

In this example, the tool attempts to broadcast channel inputs to two identical blocks; an error is generated because blocks that were specified to be identical are not identical because they have a different number of output channels.

```
analyze_compression -edt_block block1 -chain 100 -input_channels 3 -output_channels 2 \  
-edt_block block2 -chain 100 -input_channels 3 -output_channels 3 \  
-broadcast_all_channels_to_identical_blocks block1 block2  
  
// Error: EDT block 'block1' and 'block2' are non-identical due to  
// different number of output channels.  
// '-broadcast_all_channels_to_identical_blocks' is not allowed.
```

Case 6:

In this example, the tool attempts to broadcast channel inputs to two identical blocks; an error is generated because blocks that were specified to be identical are not identical because they have a different number of scan chains.

```
analyze_compression -edt_block block1 -chain 100 -input_channels 3 -output_channels 2 \  
-edt_block block2 -chain 120 -input_channels 3 -output_channels 2 \  
-broadcast_all_channels_to_identical_blocks block1 block2  
  
// Error: EDT block 'block1' and 'block2' are non-identical due to  
// different number of scan chains.  
// '-broadcast_all_channels_to_identical_blocks' is not allowed.
```

Case 7:

In this example, Chain1 in block1 has 400 scan cells and Chain1 in block2 has 500 scan cells. The tool attempts to broadcast channel inputs to these two identical blocks. An error is generated because blocks that were specified to be identical are not identical because Chain1 in block1 has a different number of scan cells than Chain1 in block2.

```
analyze_compression -edt_block block1 -chain 100 -input_channels 3 -output_channels 2 \  
    -edt_block block2 -chain 100 -input_channels 3 -output_channels 2 \  
    -broadcast_all_channels_to_identical_blocks block1 block2  
  
// Error: EDT block 'block1' and 'block2' are non-identical due to  
//      different number of scan cells on chain 'Chain1'.  
//      '-broadcast_all_channels_to_identical_blocks' is not allowed.
```

Case 8:

In this example, the tool attempts to broadcast channel inputs to two different groups of identical blocks; an error is generated because one of the blocks is defined as a member of two different groups of identical blocks.

```
analyze_compression -edt_block block1 -chain 100 -channel 4 \  
    -edt_block block2 -chain 100 -channel 4 \  
    -edt_block block3 -chain 100 -channel 4 \  
    -broadcast_all_channels_to_identical_blocks block1 block2 \  
    -broadcast_all_channels_to_identical_blocks block2 block3  
  
// Error: EDT block 'block2' show up in two groups."
```

Case 9:

In this example, the tool attempts to broadcast channel inputs to a block that is specified in both a group of identical blocks and a group of non-identical blocks.

```
analyze_compression -edt_block block1 -chain 100 -channel 4 \  
    -edt_block block2 -chain 100 -channel 4 \  
    -edt_block block3 -chain 200 -channel 5 \  
    -broadcast_all_channels_to_identical_blocks block1 block2 \  
    -share_data_channels block2 block3 -data_and_control_channels 6  
  
// Error: EDT block 'block2' show up in two groups."
```

Example 20

In this example, there are 100 chains, named “chain1, chain2, ..., chain100” and the first four chains are set to uncompressed chains:

```
analyze_compression -uncompressed_chains chain1 chain2 chain3 chain4 -channels 4 -chain 50
```

Issuing this command specifies that chain1 to chain4 are uncompressed chains, while the scan cells in the remaining 96 chains are evenly distributed among 50 chains. These 50 chains are compressed with 4 EDT channels.

Example 21

In this example, there are 100 chains in an EDT design, and the first 4 chains are already uncompressed chains:

```
analyze_compression -edt_block blk1 -channels 4 -chain 50 -edt_block blk2 -channel 4 -chain 50
```

Issuing this command maintains the first 4 chains as uncompressed chains, while the scan cells in the remaining 96 chains are evenly distributed among 100 chains (50 chains in each of the two EDT block).

Example 22

In this example, there are 100 chains (chain1 through chain100) in an EDT design, and the first 4 chains are uncompressed chains. To add two more uncompressed chains (chain5 and chain6) during the emulation, you would issue the following command:

```
analyze_compression -uncompressed_chains chain5 chain6 -channels 4 -chain 50
```

This treats the first 6 chains as uncompressed chains, while the scan cells in the remaining 94 chains are evenly distributed among 50 chains, and these 50 chains are compressed with EDT of 4 channels.

Example 23

In this example, there are 100 chains (chain1 through chain100) in an EDT design, and the first 4 chains are uncompressed chains. To replace these uncompressed chains with new uncompressed chains (chain5 and chain6) during the emulation, you would issue the following command:

```
analyze_compression -no_keep_uncompressed_chains \  
-uncompressed_chains chain5 chain6 -channels 4 -chain 50
```

This treats chain5 and chain6 as uncompressed chains, while the scan cells in the remaining 98 chains are evenly distributed among 50 chains, and these 50 chains are compressed with EDT of 4 channels.

analyze_control_signals

Context: `dft -edt`, `dft -scan`, `patterns -scan`, `patterns -scan_diagnosis`

Mode: `setup`, `analysis`

Identifies and optionally defines the primary inputs of control signals.

Usage

`analyze_control_signals [-Report_only | -Auto_fix] [-Verbose]`

Description

The `analyze_control_signals` command identifies each control signal (clocks, set, reset, write-control, read-control, and so on) of every sequential element (for example, DFF, latch, RAM, ROM) and optionally defines its primary input as a control signal. The purpose of analyzing the control signals is to identify the primary inputs that need to be defined as a clock, read-control, or write-control. This analysis also considers pin constraints, but only traces through simple combinational gates.

If the `-Verbose` option is specified, the tool issues messages that indicate why certain control signals are not reported. At the end of the analysis, the tool displays statistical information such as the number of primary inputs identified as control signals, their types, and additional information.

If the `-Auto_fix` option is specified, all identified primary inputs of control signals are automatically defined. For example, when a clock is identified, an implicit `add_clocks` command is performed to define the primary input. By default, all control signals are only reported.

This command performs the flattening process automatically, if run prior to performing flattening.

Note

The tool defers to your expert knowledge when you use `add_clocks` to define a clock; the `-Auto_fix` option does not alter a clock definition specified by a preceding [add_clocks](#) command.

dft -scan Details

Because it is not possible to completely identify all control signals, you should only use the results of this command as a starting point in creating a dofile that defines the clock control signals, read and write controls in a design. You should use this dofile when the tool is being used for production scan and test logic insertion. Situations where the tool may not be able to identify particular control signals include the following:

- When the tool is unable to trace or simulate through complex logic, the tool cannot identify a top-level pin as a clock. These cases include clocks driven by PLLs or clock

gates that require simulating a test setup procedure to obtain a sensitizable path to a top-level pin.

- The tool cannot accurately predict the off-state of a clock by observing the flip-flops it is driving and, therefore, requires the user to verify that the off-state of the clock/set/reset lines is correct.

Because of these types of issues, this command does not identify all clocks, their off-states, or controls signals. In this case, you should explicitly add the unidentified clocks using the [add_clocks](#) command.

Arguments

- **-Report_only**
An optional literal that specifies to identify control signals only (does not define the primary inputs as control signals). This is the invocation default.
- **-Auto_fix**
An optional literal that specifies to define the primary inputs of all identified control signals as control signals. For example, when a clock is identified, an implicit `add_clocks` command is performed to define the primary input.
- **-Verbose**
An optional literal that specifies to display information on control signals (whether they are identified or not, and why) while the analysis is performed.

Examples

The following example analyzes the control signals, then only provides a verbose report on the control signals in the design. After examining the transcript, you can then perform another analysis of the control signals to add them.

analyze_control_signals -verbose

```
// command: analyze_control_signals -reports_only -verbose
```

```
// Begin control signals identification analysis.
-----
// Warning: Clock line of '/cc01/tim_cc1/add1/post_latch_29/WRITEB_reg/r/
// (7352)' is uncontrolled at '/IT12 (4)'.
...
...
...
// Identified 2 clock control primary inputs.
//   /IT23 (5) with off-state = 0.
//   /IT12 (4) with off-state = 0.
// Identified 0 set control primary inputs.
// Identified 1 reset control primary inputs.
//   /IRST (1) with off-state = 0.
// Identified 0 read control primary inputs.
// Identified 0 write control primary inputs.
-----
// Total number of internal lines is 105 (35 clocks, 35 sets , 35 resets,
// 0 reads, 0 writes).
// Total number of controlled internal lines is 25 (17 clocks, 0 sets ,
// 8 resets, 0 reads, 0 writes).
// Total number of uncontrolled internal lines is 80 (18 clocks, 35 sets,
// 27 resets, 0 reads, 0 writes).
// Total number of added primary input controls 0 (0 clocks, 0 sets ,
// 0 resets, 0 reads, 0 writes).
-----
```

analyze_drc_violation

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -ijtag, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Generates a schematic in the schematic windows of the portion of the design involved with the specified rule violation number.

Usage

analyze_drc_violation *rule_id-occurrence#* [-append]

Description

When you issue the `analyze_drc_violation` command, the tool includes different simulation data in the netlist depending on the type of rule violation. The tool automatically opens the schematic windows of Tessent Visualizer if it is not already open, and sets the gate reporting to match the type of rule violation, just as if you had manually issued the `set_gate_report` command. The gate report setting is shown on the status bar. For some DRC violations (E5 for example), the gate level is automatically set to primitive.

Note that the following DRC errors do not have additional information that can be displayed with Tessent Visualizer:

- B1—B16
- E1, E12, E13, E14
- G rules
- K rules
- P rules
- T1, T8—T11, T13—T15, T18—T23
- W1—W19, W32, W33

For more information about displaying DRC information, refer to the [report_drc_rules](#) command. For information about each DRC, refer to “[Design Rule Checking](#)” on page 2989.

Arguments

- *rule_id-occurrence#*

A literal and integer argument pair that specifies the exact design rule violation (including the occurrence) that you want to analyze. The tool traces the violation back to the probable cause and then the schematic viewer displays all the gates in that trace. The argument must include the design rules violation ID (*rule_id*), the specific occurrence number of that violation, and the hyphen between them. For example, you can analyze the second occurrence of the C3 rule by specifying C3-2. The tool assigns the occurrences of the rules

violations as it encounters them, and you cannot change either the rule identification number or the ordering of the specific violations.

- **-append**

An optional switch that specifies to append the new schematic to the existing contents of the schematic windows instead of replacing the contents. If you do not specify the **-append** switch, the existing schematic is deleted and new data is shown in the schematic windows.

Examples

The following example defines the off-state of a clock incorrectly, causing a C2 rule violation. When a rule violation occurs, you can use the schematic windows to analyze the probable cause of the error.

With this example, the schematic windows display the sequential element associated with the `clk` input, along with a backward trace through the gates and nets to the associated primary input.

```
add_clocks 0 clk  
set_system_mode analysis  
  
...  
// -----  
// Begin scan clock rules checking.  
// -----  
// 1 scan clock/set/reset lines have been identified.  
// All scan clocks successfully passed off-state check.  
// Error: Clock /CLK cannot capture data with other clocks off. (C2-1)  
  
analyze_drc_violation c2-1
```

analyze_fault

Context: dft -edt, patterns -scan

Mode: analysis

Performs an analysis to identify why a fault is not detected and optionally displays the relevant circuitry in Tessent Visualizer.

Usage

Struck/Transition Usage

```
analyze_fault pin_pathname {-Stuck_at {0 | 1} | -Rise | -Fall}  
[-Observe gate_id#] [-Boundary] [-Continue] [-Display [APpend]]
```

UDFM Usage

```
analyze_fault instance_pathname -Udfm_type name  
[{-Cell name | -Module name}] {-Fault name | -Bridge -Id bridge_id}  
[-Observe gate_id#] [-Boundary] [-Continue] [-Display [APpend]]
```

Path Delay Usage

```
analyze_fault path_name {-Rise | -Fall} [-Observe gate_id#] [-Auto] [-Display [APpend]]
```

Description

The `analyze_fault` command performs an analysis to identify why the fault that you specify was not detected. You can use the `-Observe` switch to specify the observe point for the sensitization analysis.

If you are using Tessent Visualizer, you can specify the `-Display` switch to graphically display the relevant circuitry for any fault detection. This may assist you in identifying either why a fault wasn't detected or how a fault was detected.

The fault analysis performed by the `analyze_fault` command consists of the following actions:

1. A message is given if the selected fault has been nofaulted.
2. A message is given to identify if the fault is in the current fault list. If the fault is in the current fault list and the fault is the representative member, its fault classification shows the fault class and the subclass information.
3. If the fault was not identified as included in the active fault list, the basic fault analysis is performed that determines if the fault can be classified as unused, tied, blocked, or detected by implication.
4. If the fault category is detected by simulation, detected by implication, or unused, a message is given and the analysis is terminated. You can override the termination by using the `-Continue` switch.
5. If the fault category is tied, all sources of the tied condition are identified and the analysis is terminated.

6. If the fault category is blocked, all blockage points (100 maximum) are identified. For each blockage point, all sources of the tied conditions causing the blockage are identified. The analysis then terminates.
7. The states that result from all constrained pins and stable non-scan cells are calculated.
8. If the fault site is now prevented from attaining the necessary state, a message is given indicating the fault is tied by constrained logic, all sources of the tied condition are identified, and the analysis then terminates.
9. An analysis is made to identify all blockage points (100 maximum) and all potential detection points (25 maximum).
10. If there are no potential detection points, the blockage points are identified and for those points blocked by tied logic, all sources of the tied condition are identified. The analysis then terminates.
11. If there were potential detection points, the detection points are identified (25 maximum).
12. A controllability test generation is performed to determine if the fault site can be controlled. If successful, the test generation values are displayed using “set_gate_report parallel_pattern 0”. If unsuccessful, the analysis then terminates.
13. If an observe point is not selected, a complete test generation is attempted where the fault is sensitized from the fault site to any unblocked point. Potential problem points in any sensitization path are identified. The points include tri-state driver enable lines, transparent latch data lines, clock_pos, wire gates, latch and flip-flop set/reset/clock lines, RAM write/read/address/data lines, and ROM read/address lines. If the test generation is successful, the test generation values are displayed using “set_gate_report parallel_pattern 1”.
14. If an observe point is selected, the fault is sensitized from the fault site to the observe point. Potential problem points in the sensitization path are identified. If the sensitization is successful, the test generation values are displayed using “set_gate_report parallel_pattern 1”.

Note

 Only UDFM, stuck-at, path delay, and transition fault types can be analyzed using the analyze_fault command.

When the fault type is path delay, the analyze_fault command performs an unsensitizable path analysis when the ATPG run is unable to create a test pattern. If the analysis finds that some segment of the path is unsensitizable, it attempts to find a minimum number of gates in the path that are required to prove the path unsensitizable.

For example:

```
analyze_fault path37 -s 0
```

produces the following report:

```
// -----  
// Path delay fault analysis for path37 slow to rise on  
// launch point = 22032, capture point = 167521  
// -----  
// Path delay test generation not successful for capture point = 167521  
// due to atpg_untestable.  
// Begin unsensitizable path analysis for path=path37  
// Cycle=0 path sensitization check failed status=redundant  
// Simultaneous sensitization of 2 path segments cannot be achieved  
// (status=redundant).  
// These are:  
//     OR   145279 (I1) + ;  
//     ...  
//     AND  150252 (I1) + ;  
// Path is a static unsensitizable path. Robust detection will be  
// impossible.
```

The `analyze_fault` report shows that it is impossible to use both input 1 (the second input, inputs are numbered starting at 0) of the OR gate 145279 while at the same time using input 1 of the AND gate 150252. The ellipsis (...) indicates that there are other gates in the path between the reported gates that are not relevant to the unsensitizable path problem.

The “`delete_fault_sites -Unsensitizable_paths`” command lets you delete proven unsensitizable paths.

When the fault type is transition, the `analyze_fault` command performs the following analysis steps:

1. The controllability of logic value 0 and 1 at the fault site is analyzed.

If the analysis succeeds, the fault site is controllable. You can access the analysis results by setting the gate report type to be parallel pattern 0(2) to set logic value 1(0) at the fault site for a slow-to-rise fault, or logic value 0(1) at the fault site for slow-to-fall fault.

If the tool aborts this step or it otherwise fails, the fault cannot be detected due to a lack of controllability at the fault site. The tool then terminates the analysis unless you force it to continue.

2. The ability to launch a slow-to-rise (0 -> 1) or slow-to-fall (1 -> 0) transition at the fault site is analyzed.

If the analysis succeeds, the transition you need can be created at the fault site. You can access the analysis results by setting the gate report type to be parallel pattern 3.

If the tool aborts this step or it otherwise fails, the fault cannot be detected because a transition cannot be launched at the fault site. The tool terminates the analysis unless you force it to continue.

3. The tool attempts to generate a test pattern for the transition fault being analyzed.

If successful, a test pattern exists to detect the fault. You can access the analysis results by setting the gate report type to be parallel pattern 1 and the analysis process terminates.

If the tool aborts this step or it otherwise fails, the tool proceeds to the next step.

4. The tool attempts to generate a test pattern for a stuck-at fault at the same fault site.

If successful, there exists a sensitive path from the fault site to an observation point. The reason for aborting or failing to generate the test pattern for the original transition fault is that launching a transition at the fault site may block the fault propagation path. You can access the analysis results for the stuck-at fault by setting the gate report type to be parallel pattern 4.

Arguments

- ***pin_pathname***
A required string that specifies the pin pathname of the fault where you want to perform stuck/transition analysis.
- ***path_name***
A required string that specifies the pathname where you want to perform path delay analysis.
- ***instance_pathname***
A required string that specifies the instance for which you want to perform UDFM fault analysis.
- **-Stuck_at 0 | 1**
A switch and literal pair that specifies the stuck-at fault value that you want to analyze. The stuck-at values are as follows:
 - 0** — A literal that specifies that the tool analyze the *pin_pathname* for a “stuck-at-0” fault.
 - 1** — A literal that specifies that the tool analyze the *pin_pathname* for a “stuck-at-1” fault.
- **-Rise**
A switch that specifies a slow-to-rise transition fault.
- **-Fall**
A switch that specifies a slow-to-fall transition fault.
- **-Udfm_type name**
A required switch and value pair that identifies the type of UDFM fault to analyze.
- **-Cell name | -Module name**
An optional switch and value pair that identifies the cell or module containing a UDFM fault.

- **-Fault *name***
An optional switch and value pair that identifies the UDFM fault to analyze.
- **-Bridge -Id *bridge_id***
An optional switch, and switch and value pair, that specifies an identifier for a UDFM bridge fault to analyze.
- **-Observe *gate_id#***
An optional switch and integer pair that specifies the observe point for the sensitization analysis.

gate_id# — An integer that specifies a gate identification number whose location you want to use as the observe point for the sensitization analysis.
- **-Boundary**
An optional switch that specifies to display the boundary faults when analyzing an ATPG untestable, tied, blocked, or redundant fault.
- **-AUto**
An optional switch, applicable only to path delay faults, that automatically determines how far along the path the tool can successfully propagate a path delay fault.
- **-Continue**
An optional switch that forces the tool to complete the analysis of faults that have already been detected by the pattern set. This lets you inspect the generated pattern by using the `report_faults` command.
If you do not specify this switch and the tool detects the fault category by simulation, by implication, or as unused, then the tool displays a message and terminates the analysis.
- **-Display [APpend]**
An optional switch and literal pair that causes the tool to create a gate list relevant to the fault being analyzed and to update the Tessent Visualizer Flat Schematic window with this information. If the Append switch is included, the information is added to the existing contents of the Flat Schematic window.

The schematic view contains annotations for the following cases as required:

- **Successful ATPG** — All gates that sensitize the fault effects to an observable point are added to the gate list. The pins on these gates are annotated with the simulated value that results from the pattern that was created.
- **Uncontrollable Fault Site due to Forbidden Conditions** — All gates that prevent the fault site from attaining the required state are added to the gate list. The pins on these gates are annotated with the `constrain_value` data.
- **Blocked Fault Site due to Forbidden Conditions** — All gates that sensitize the fault effects to the blockage point and all gates that prevent the blockage points from

attaining the necessary values are added to the gate list. The pins on these gates are annotated with the constrain_value data.

Examples

The following example performs test pattern generation, then performs an analysis to determine why the tool did not detect a stuck-at-1 fault at pin /ram_32_36/u_tcb/tcbreg_inst/SHIFT_0/Q_reg/inst_2/Q:

```
set_system_mode analysis
create_patterns
report test data -class au
```

```
// fault analysis summary of 17 faults
// number faults tied by constraints = 7
// number faults connected to nonscan_latch = 15
// number faults connected to clock/set/reset = 8
// number faults connected from clock = 6
// number faults connected from nonscan_latch = 7
// number faults unclassified = 0
```

```
report_faults -class au
```

1	AU.TC	/ram_32_36/u_tcb/tcbreg_inst/SKEW/Q_reg/inst_2/CP
1	AU.TC	/ram_32_36/u_tcb/tcbreg_inst/SKEW/Q_reg/inst_2/D

```
analyze_fault /ram_32_36/u_tcb/tcbreg_inst/SHIFT_0/Q_reg/inst_2/Q -stuck_at 1
```

```
// -----
// Fault analysis for /ram_32_36/u_tcb/tcbreg_inst/SHIFT_0/Q_reg/inst_2
// (29217) output Q stuck at 1
// -----
// Current fault classification = AU.TC
// Fault site sequential depth: Control_0 = 255, Control_1 = 0, Observe = 255.
// Fault site is tied to 1 due to constrained logic.
// Tied gate source: 1 /ram_32_36/u_tcb/tcbreg_inst/SHIFT_0/Q_reg/inst_2
// (29217)
```

The following example analyzes a UDFM fault with multiple test alternatives:

UDFM Content:

```
UdfmType ("UDFM_sff_test") {
    Cell ("sff") {
        ...
        Fault ("f6") {
            Test {Impact:100;StaticFault{"D":0;} Conditions{"D":0;}}
            Test {Impact:100;StaticFault{"D":0;} Conditions{"Q":0;}}
        }
    }
}
```

Example analyze_fault report:

analyze_fault U_2 -fault f6 -udfm_type UDFM_sff_test

```
// -----
// Fault analysis for UDFM fault UDFM_sff_test/sff/f6
// -----
// Current fault classification = AU (atpg_untestable)
// Analyzing test alternative 1...
// Fault location '/U_2/' (16) sequential depth: Control_0 = 0, Control_1 = 0,
// Observe = 1.
// Analyze if the fault location can be controlled without active conditions...
//   The fault location was set to 1 successfully.
// Analyze if the condition D can be justified...
// Test condition justification failed.
// Search potential observation point...
//   Fault effect is blocked at /U_2 (20) due to unobservable scan cell.
//   The fault effect cannot propagate to any observation point.
// Analyzing test alternative 2...
// Fault location '/U_2/' (16) sequential depth: Control_0 = 0, Control_1 = 0,
// Observe = 1.
// Analyze if the fault location can be controlled without active conditions...
//   The fault location was set to 1 successfully.
// Analyze if the condition Q can be justified...
// Test condition justification passed.
// Analyze if the fault location can be controlled with active conditions ...
//   The fault location can be controlled with active conditions.
// Search potential observation point...
//   Fault effect is blocked at /U_2 (20) due to unobservable scan cell.
//   The fault effect cannot propagate to any observation point.
//
// Fault analysis summary
//
// UDFM fault: 'UDFM_sff_test/sff/f6'
// Current fault classification: AU
// Test 1: Status=unobservable
//   Fault location: State=stuck-0, '/U_2/' (16)
//   Condition D: State=0, Location='/U_4/Y' (14), Status=not justified
// Test 2: Status=unobservable
//   Fault location: State=stuck-0, '/U_2/' (16)
//   Condition Q: State=0, Location='/U_2/Q' (11), Status=justified
```

analyze_graybox

Context: patterns -scan, patterns -ijtag

Mode: analysis

Identifies the instances and nets to be included in the graybox netlist by automatically setting their `in_graybox` attributes to true. Subsequently, a “write_design -graybox” command writes out the graybox netlist for the marked instances and nets.

Usage

Context: patterns -scan

```
analyze_graybox [-scan] [-preserve_instances instance_objects]  
                [-max_sequential_levels {number | unlimited}] [-collect_reporting_data]
```

Context: patterns -ijtag

```
analyze_graybox [-ijtag] [-preserve_instances instance_objects]
```

Description

Notes About the Scan Graybox Analysis

The Scan graybox analysis is only supported in the `-no_rtl` context. It is performed in analysis mode when the external scan mode successfully completed DRC.

All module names, except the top-level module, are uniquified by adding a prefix in the generated graybox netlist. You can change the default prefix by using the `-edited_module_prefix` option of the [set_scan_insertion_options](#) command.

Modules with the `exclude_from_concatenated_netlist` attribute set to true are not included inside the graybox netlist and their module names are not changed. This enables you to still bind the real simulation model of the hard macros such as memories or PLL models during simulation with the scan graybox views. Child physical region modules are uniquified and pruned into the parent block’s scan graybox if anything within them is part of the scan mode. A child physical region module is recognized with the `is_physical_module` attribute being set to true.

The scan graybox analysis performs the identification by tracing backward from all primary output pins, wrapper chain sequential cell input pins, and specified `preserve_instance` input pins. In general, the backward tracing used by the scan graybox analysis considers a path sensitization based on the state-stability values. These values are obtained by simulating the pin constraints and test-setup procedures provided for the external test mode. However, a pure structural tracing method is used when tracing backward from `preserve_instance` input pins.

Additional gates are included in the scan graybox to minimize the fault coverage differences in the fault list between when the graybox netlist is used and when the complete netlist is used. If a gate has multiple fanouts in the complete netlist, then it must also have at least two fanouts in the graybox netlist. The tool includes additional gates in the graybox netlist to maintain a fanout

of at least two for each of the gates that was originally identified during the feedback analysis. This is done to avoid inaccuracy in equivalent fault accounting between the two netlists.

Exclude the scan-out pins of the core chains from the backward tracing to prevent marking internal (core) logic for the scan graybox. To do this, set the `ignore_for_graybox` attribute of the scan-out pins to true using the `set_attribute_value` command.

Use the `-preserve_instances` option to include arbitrary instances (the instantiations of modules or the instantiations of library models) in the scan graybox view. The tool bypasses the graybox analysis within specified preserve module instances and automatically includes all of their sub-instances and nets in the scan graybox view. This enables you to overcome the limitations imposed by the sensitized path-based backward tracing, such as not permitting complex test_setup procedures that initialize non-scan cells in clocks paths and limit the sequential depth.

One typical `-preserve_instances` option usage is when the design includes a user-defined clock control module. You can specify the entire module as a `preserve_instance` if it cannot be identified by the scan graybox analysis.

To understand the reason why a given instance was preserved in the scan graybox, display the value of the `in_graybox_reason` attribute after you have called `analyze_graybox` in analysis mode.

The tool automatically adds certain categories of instances to the list of preserved instances during scan graybox generation.

- It automatically preserves instances of the EDT logic identified by EDT Finder and EDT logic in the channel pipeline stages, as EDT Finder is enabled by default. If you have turned off EDT Finder, use the `-preserve_instances` option to preserve these instances.
- It automatically preserves all instrument instances that you define using the `add_core_instances` command. For more information, refer to [Tessent Core Description \(TCD\)](#) in the *Tessent TestKompress User's Manual*.

Note

 This only applies if you use EDT in the external mode so the tool defines EDT in the current mode when performing graybox analysis. If you do not use an EDT controller in the core for external test, it does not need to be preserved in the external mode.

- If you are using IJTAG and have an ICL description of the current design, then any ICL instance that is identified as part of the scan resource network and that can be mapped to a design instance is automatically preserved. An ICL module is identified as a Scan Resource Instrument when it has the ICL module attribute `keep_active_during_scan_test` not set to false. If you create the scan instrument using the Tessent tools (for example, an EDT controller), and insert the IJTAG network using the `create_dft_specification` and `process_dft_specification` commands, the

keep_active_during_scan_test attribute is already added by the tool. For more information, refer to [IJTAG Network Insertion](#) in the *Tessent IJTAG User's Manual*.

Note

 The tool adds all instances marked with the preserve_in_graybox attribute to the list of instances specified with the -preserve_instances switch and handles them in the same way.

You can also set the preserve_in_graybox attribute on individual nets. This includes the specified net, but does not include the affected instances, and should be used with caution because you need to manually identify the instances that are connected to the net and make sure they are either preserved automatically, or specified with the -preserve_instances switch, or by also setting the attribute on the instances.

Currently, Tessent only supports Mux-DFF scan architecture with the graybox functionality.

For more information about scan graybox concepts and procedures, refer to [Graybox Overview](#) in the *Tessent Scan and ATPG User's Manual*.

Notes About the IJTAG Graybox Analysis

The IJTAG graybox analysis works in both RTL and netlist mode, but there are several differences in the output files based on the mode.

In netlist mode, the tool creates a single concatenated file with everything that needs to be preserved in the IJTAG graybox view. It instantiates child physical blocks but does not include their module definitions in the parent's IJTAG graybox. This is different from the scan graybox view which may include the pruned child physical block module definitions if anything from them is needed in the given scan mode. It includes IJTAG instances located with child sub-blocks in the IJTAG graybox view of their parent physical block. Refer to the [set_design_level](#) command for a definition of physical block versus sub-block.

In the RTL mode, the IJTAG graybox is composed of the pruned logic interconnecting the IJTAG, and the user-specified preserve_instances between them, and the primary inputs and outputs. The pruned modules are all written into a single file per language or format combination. Those files only include the instantiation of IJTAG and user-specified full preserve_instances. A design load dictionary is created with read entries for each created concatenated file and a read entry for the original module definitions of the IJTAG and user-specified full preserved instances. The child physical block and child sub-block are instantiated in the pruned modules but their module definitions are not referenced within the design load dictionary. Use “[read_design](#) -view full| ijtag_graybox | interface” on the child blocks to load the view you need.

Note

 The IJTAG graybox includes any combinational feed-through in your design. You can use the feature to create a graybox view of your feed-through logic even if you do not have any IJTAG instance to preserve. To go into analysis mode of the patterns -scan context without an ICL model, call “add_icl_port -type data_in” on any of your input ports to bypass the condition.

In RTL mode, the recommended method for creating the IJTAG graybox view is as part of the [extract_icl](#) command by specifying the “-create_ijtag_graybox on” switch. The [extract_icl](#) command preserves any logic between the fully preserved instances and the primary inputs and outputs, and between any groups of fully preserved instances. The pruned IJTAG graybox is constructed from the quick-synthesized view and includes the instantiation of the RTL cells, where needed. If you want to visualize the content of the IJTAG graybox, use the “read_design [get_current_design] -view ijtag_graybox -force” command.

Note

 Similarly to scan graybox analysis, you can use the -preserve_instances switch to add any existing logic to the ijtag_graybox.

To understand the reason why a given instance was preserved in the IJTAG graybox, display the value of the [in_graybox_reason](#) attribute after you have called “analyze_graybox -ijtag” in analysis mode but before you call “write_design -graybox”.

IJTAG Graybox Limitations in RTL Mode

Certain limitations can prevent creating an IJTAG graybox in RTL mode. These revolve around particular cases for VHDL modules and System Verilog modules. The situations involving these limitations are uncommon, so creating an RTL IJTAG graybox should be possible for most designs.

- Limitations for all VHDL modules

You must use quick synthesis to synthesize any VHDL module that needs to be pruned and kept in the IJTAG graybox. If you do not synthesize such a module, the tool reports an error listing the modules for which you must force synthesis using the `synthesize_before_analysis` module-level attribute.

- Limitations for top modules of physical and sub-blocks written in VHDL

These modules can only have simple ports such that the port names do not change between the RTL and the quick-synthesized views. Generics and parameters are also not permitted in these top-level VHDL modules. This limitation is only for the top VHDL module of a physical or sub-block and does not apply to lower VHDL modules.

- Limitations for top module of physical and sub block written in System Verilog

These modules may not contain ports with unpacked or enum types defined in the \$unit space. They may have such ports if their types are declared within packages.

Arguments

- -ijtag

An optional switch that specifies to generate an IJTAG graybox. This switch is inferred when you invoke the `analyze_graybox` command within the “patterns -ijtag” context.

This switch is only available if you have an SSN license.

The tool automatically does the IJTAG graybox analysis within the `extract_icl` and “`write_design -tsdb`” commands. When you run `extract_icl` after the `process_dft_specification` command in the `no_rtl` mode, the tool cannot automatically extract the IJTAG graybox because the newly inserted IJTAG instruments are not yet synthesized, and thus could not be included into the concatenated IJTAG graybox netlist. When you invoke `extract_icl` with the `-create_ijtag_graybox` switch in the above situation, the tool generates the following warning:

```
// Warning: The IJTAG graybox was not generated because module
definitions
//          matched to ICL instruments are not loaded in memory.
//          In order to generate the IJTAG graybox, issue the
following commands in setup mode:
//
//          run_synthesis
//          set_context patterns -ijtag
//          read_design chip_top -force
//          set_current_design chip_top
//          set_system_mode analysis
//          analyze_graybox -ijtag
//          write_design -tsdb -graybox
//
//          Here is the list ICL modules for which actual modules
are not in memory:
//          chip_top_gate_tessent_bscan_interface
//          chip_top_gate_tessent_sib_pb1
//          chip_top_gate_tessent_sib_pb2
//          chip_top_gate_tessent_sib_pb3
//          chip_top_gate_tessent_sib_sri
//          chip_top_gate_tessent_tap_main
```

- -scan

An optional switch that specifies to generate a scan graybox. This switch is inferred when you invoke the `analyze_graybox` command within the “patterns -scan” context.

- -preserve_instances *instance_objects*

An optional switch that specifies a collection of one or more instances or a well formatted Tcl list of one or more instance names. The tool forces the specified instances to be preserved into the graybox view. It also automatically preserves the combinational logic between the preserved instances, and between the preserved instances and the primary inputs and outputs.

- `-max_sequential_levels {number | unlimited}`

An optional switch and integer or literal pair that is only relevant to the scan graybox analysis. It specifies the number of levels of non-scan cells when tracing back from the POs or from the data input pins of the wrapper cells before reaching the PIs or other wrapper cells. If the specified sequential levels limit is exceeded during backtracing, all the logic so far traced from the origin pin is dropped and not included in the graybox netlist. The limit specified by this switch does not apply to the backtracing from the clock, set, reset and scan enable pins of the wrapper cells. Sequential cells initialized to constant values (Tie-0 or Tie-1) with an active set or reset pin are not counted as sequential levels during backtracing. The “number” argument can accept a value of 0 or greater, where 1 is the default value when this switch is not specified with the command. The “unlimited” argument specifies to not limit the number of sequential levels during backtracing.

- `-collect_reporting_data`

An optional switch that is only relevant to the scan graybox analysis. It specifies to count the number of leaf instances (library model instances at design level) that are marked for each backward tracing origin, such as a PO, a wrapper cell input pin, or a “preserve_instance” input pin (all input pins combined). This switch is required if you want to use the [report_graybox_statistics](#) command to report the collected data. Collecting reporting data requires additional netlist tracing and could impact analysis execution performance.

Examples

The following command performs graybox analysis on the current design. The module instance “tap_ctrl_ins” and all sub-instances within are marked for graybox logic without going through the graybox analysis.

```
analyze_graybox -preserve_instances tap_ctrl_ins -collect_reporting_data  
report_graybox_statistics -top 10
```

analyze_icl_suspect

Context: patterns -silicon_insight -ijtag

Mode: setup

Analyzes the suspects for a configured scan path of interest.

Usage

```
analyze_icl_suspect {suspect_signature | -verify_scan_path} [-pattern_type {stil | svf}]  
[-report]
```

Description

You can analyze the ICL network by either specifying a suspect signature or the -verify_path_switch.

Use this command when manually debugging IJTAG networks as described in “[Diagnosing and Debugging IJTAG Networks](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

When you specify a suspect signature, the tool isolates the suspect node based on the signature, performs analysis with setup and flush patterns, and returns a diagnosis result that indicates what type of defect could be causing the observed behavior. The possible results are:

Table 3-17. Suspect Signature Diagnosis Results

Result	Description
?	Indeterminable state. Refer to “ Manually Debugging an IJTAG Network ” in the <i>Tessent SiliconInsight User’s Manual for Tessent Shell</i> .
good	Functions as designed.
register_stuck@0	One or more flops in the register suspect are stuck at 0.
register_stuck@1	One or more flops in the register suspect are stuck at 1.
register_inconsistent_length@icl_length@dut_length	Inconsistent length specified in the ICL and observed from the DUT. For example: register_inconsistent_length@16@17 This message indicates that the length specified in ICL is 16 while the length observed from the DUT is 17.
sib_stuck@0	The SIB is stuck at 0 (client mode).
sib_stuck@index	The SIB is stuck at host mode for the specified index, where the index is 1 or higher.
mux_stuck@index	The scan mux is stuck at input at the specified index.

When you specify the -verify_path_switch, the tool assumes that you have already configured a scan path of interest from TDI to TDO and performs verification of the scan path.

Arguments

- ***suspect_signature* | -verify_scan_path**

A required choice between specifying a suspect signature or the `-verify_scan_path` switch.

suspect_signature — Specify the suspect signature in the format *suspect_name*[*@input_index*], where the suspect name can be the hierarchical name of a scan register, scan mux, or SIB as returned in the diagnosis results suspects list. The tool assumes a 0 state.

For SIBs, the input index is the host input with 0 reserved for client mode. For scan muxes, the input index is the programmed selected input.

-verify_scan_path — This switch returns a pass or fail result for the scan path of interest.

- `-pattern_type {stil | svf}`

An optional switch and literal pair that specifies the pattern type—STIL or SVF—for the generated temporary (setup and flush) patterns that are run to analyze the scan path. The default is SVF.

- `-report`

An optional switch that prints the analysis results to the transcript.

Examples

```
analyze_icl_suspect block1_I1.sib1@1 -report
```

```
analyze_icl_suspect block1_I1.tdr1.R[7:0]
```

```
analyze_icl_suspect -verify_scan_path -pattern_type stil
```

analyze_layout_hierarchy

Context: patterns -scan_diagnosis

Mode: setup

Analyzes the layout LEF/DEF hierarchy and stores the analysis results in a layout hierarchy database.

Usage

```
analyze_layout_hierarchy layout_hierarchy_db_dir [ -lef lef_filename ... | -leflist leflist ]  
    [ -def def_filename ... | -deflist deflist ] [ -replace ] [ -threads N ]
```

Description

This command generates a layout hierarchy database that stores the layout hierarchy of the LEF/DEF designs. By default, the tool performs multi-threaded analysis. Specify this command as a one-time setup step before loading the flat model and pattern files, and specifying the `create_layout` command.

After analyzing the layout hierarchy, the tool generates a layout hierarchy database that contains the results of the analysis. From this database, you can:

- Report estimates of the resources required to generate an LDB.
- Ensure that only one top DEF module exists.
- Optimize chip-mapped core-level LDB creation times when you are working with hierarchical designs.

Refer to “[Estimation of Resources Required for Generating LDBs](#)” in the *Tessent Diagnosis User’s Manual* for more information.

Arguments

- *layout_hierarchy_db_dir*

A required string that specifies the name of the layout hierarchy database that contains the results of the analysis, as follows:

- *layoutHierarchy.hierdb*—Database the describes the layout hierarchy.
 - *def_hierarchy_info.gds*—GDSII file of the DEF file structures.
 - *def_hierarchy_info.gds.layerprops*—Layer properties file for layout hierarchy file *def_hierarchy_info.gds*.
- `-lef lef_filename ...`
An optional switch and string that specifies space-separated name(s) of the LEF file(s).
 - `-leflist leflist`
An optional switch and string pair that specifies a Tcl list of the LEF file(s).

- `-def def_filename ...`
 An optional switch and string that specifies space-separated name(s) of the DEF file(s).
- `-deflist deflist`
 An optional switch and string pair that specifies a Tcl list of the DEF file(s).
- `-replace`
 An optional switch that overwrites the existing layout hierarchy database with the newly generated layout hierarchy database.
- `-threads N`
 An optional switch and integer pair that specifies the number of threads to run in parallel during the analysis. The default value is 0, which indicates to use all the available CPUs on the current machine, if needed. A value less than 0 uses the number of available CPUs less *N*. A value greater than 0 uses *N* CPUs. The number of threads is always capped by the number of DEF files currently being processed.

Examples

The following examples illustrate how the `-threads` option functions, where:

- `nthreads`: number of threads.
- `ncpus`: number of CPUs.
- `ndef`: number of specified DEF files.

Example 1

Suppose the maximum number of CPUs is 32 and you specified four DEF files.

Table 3-18. Example 1 -threads Option

Threads	Behavior
Undefined or 0	Use <code>nthreads = ncpus</code> Build the minimum (<code>nthreads,ndef</code>) = 4
<code>-threads 2</code>	Use <code>nthreads = minimum(threads,ncpus) = 2</code> Build the minimum (<code>nthreads,ndef</code>) = 2
<code>-threads 200</code>	Use <code>nthreads = minimum(threads,ncpus) = 32</code> Build the minimum (<code>nthreads,ndef</code>) = 4
<code>-threads -2</code>	Use <code>nthreads = ncpus-2 = 30</code> (If negative, then set to 1.) Build the minimum (<code>nthreads,ndef</code>) = 4
<code>-threads -200</code>	Use <code>nthreads = ncpus-200 = -168 = 1</code> (If negative, then set to 1.) Build the minimum (<code>nthreads,ndef</code>) = 1
<code>-threads -29</code>	Use <code>nthreads = ncpus-29 = 3</code> (If negative, then set to 1.) Build the minimum (<code>nthreads,ndef</code>) = 3

Example 2

Suppose the maximum number of CPUs is 32 and you specified 400 DEF files.

Table 3-19. Example 2 -threads Option

Threads	Behavior
Undefined or 0	Use nthreads = ncpus Build the minimum (nthreads,ndef) = 32
-threads 2	Use nthreads = minimum(threads,ncpus) = 2 Build the minimum (nthreads,ndef) = 2
-threads 200	Use nthreads = minimum(threads,ncpus) = 32 Build the minimum (nthreads,ndef) = 32
-threads -2	Use nthreads = ncpus-2 = 30 (If negative, then set to 1.) Build the minimum (nthreads,ndef) = 30
-threads -200	Use nthreads = ncpus-200 = -168 = 1 (If negative, then set to 1.) Build the minimum (nthreads,ndef) = 1
-threads -29	Use nthreads = ncpus-29 = 3 (If negative, then set to 1.) Build the minimum (nthreads,ndef) = 3

analyze_restrictions

Context: dft -edt, patterns -scan

Mode: analysis

Performs an analysis to automatically determine sources of the problem from a failed ATPG run.

Usage

All Fault Types Except IDDQ Faults Usage

```
analyze_restrictions [-Auto] [-COnflict_source_analysis]
```

IDDQ Faults Usage

```
analyze_restrictions [-INT_float_auto_except]
```

Description

The `analyze_restrictions` command reports the ATPG restrictions that caused a failed ATPG run. If you issue the `analyze_restrictions` command without an argument, the default is `-Auto`. The analysis may be lengthy depending on the number of restrictions. You can stop the analysis at any time by pressing `Ctrl-C`.

Arguments

- `-Auto`

An optional switch that automatically performs the following step-by-step analysis:

- **Step 1** — The tool identifies the type of constraints that failed the analysis.
- **Step 2** — The tool analyzes the problem constraint types and finds the minimum constraints that prevent the tool from passing the analysis.
- **Step 3** — Optional. The tool performs a detailed analysis of each constraint identified in Step 2. You perform this detailed analysis by using the `-COnflict_source_analysis` switch in conjunction with the `-Auto` switch.

The set of constraints that conflict with the constraint are reported. The tool analyzes the constraints in the following order:

- Dynamic ATPG constraints
- Dynamic cell constraints
- Static ATPG constraints
- Static cell constraints
- Named capture procedure
- Bus floating checking
- Bus contention (with the specified driver restriction)

- Port contention
- **-CONflict_source_analysis**
An optional switch that performs a detailed analysis (Step 3) of each constraint identified in Step 2 in the **-Auto** switch description. This option can increase the tool's runtime under certain circumstances.
- **-INT_float_auto_except**
An optional switch that creates Iddq exceptions automatically for the **"-int_float"** Iddq check failure sites found during the analysis. Iddq exceptions are defined for failures that are the result of **"-int_float"** Iddq checks previously specified with the **set_iddq_checks** command. You can report the automatically added exceptions with the **report_iddq_exceptions** command or use the **delete_iddq_exceptions** command to remove unwanted exceptions.

Examples

Example 1

The following example analyzes a failed ATPG run in which a user-specified ATPG constraint is conflicting with a cell constraint and causes the ATPG to fail test generation.

create_patterns

```
// Error: Current restrictions cannot be simultaneously satisfied with
// ANY abort limit. Status=atpg_untestable.
// Halting run. Suggest analyze_restrictions.
// You can specify the -NOAnalyze option in command "create_patterns"
// to force the run, but coverage will probably be low.
```

analyze_restrictions

```
// -----
// | Step-1 Global constraint analysis |
// -----
// Order-1: dynamic ATPG constraints, analysis=to_be_analyzed
// -----
// | Step-2 Identifying minimum conflicting constraint |
// -----
// Following atpg constraints conflict with the rest of constraints:
// atpg constraint: 1 dynamic /FF3/Q (10)
// You can use -conflict_source_analysis switch to analyze which
// constraints conflict with the above constraints.
```

To perform detailed analysis of the conflict, then issue the **analyze_restrictions** command with the optional **-conflict_source_analysis** switch:

analyze_restrictions -conflict_source_analysis

```
// -----  
// | Step-1 Global constraint analysis |  
// -----  
// Order-1: dynamic ATPG constraints, analysis=to_be_analyzed  
// -----  
// | Step-2 Identifying minimum conflicting constraint |  
// -----  
// Following atpg constraints conflict with the rest of constraints:  
// atpg constraint: 1 dynamic /FF3/Q (10)  
// -----  
// | Step-3 Identifying conflict source of first problem constraint |  
// -----  
// Following constraint conflicts with problem constraint #1:  
// atpg constraint: 1 dynamic /FF1/Q (8)
```

Example 2

The following IDDDQ example analyzes a failed ATPG run, displays the results of the analysis, and automatically adds an Iddq exception for each ZVAL gate that failed in an “-int_float” Iddq check. Only part of the report, about Iddq failures, is shown.

analyze_restrictions -int_float_auto_except

```
...  
// With Iddq constraints and Iddq checks removed, PASSES ability to  
// satisfy restrictions.  
// Problem is with Iddq specific restrictions. Analyzing further to find  
// problems.  
// With Iddq constraints removed, and all Set Iddq Check options removed  
// except -intfloat, FAILS.  
// Must fix -intfloat option problems to generate ANY iddq test given  
// current restrictions & circuit.  
// Will attempt to locate and report specific -int_float violators.  
// No single bus is constrained to Z (or already Z). Will analyze  
// further.  
// The following ZVAL gates cause -int_float to fail by themselves.  
// ZVAL gate /cpu/alu/U2392/ (54417). ABORTed.  
// ZVAL gate /cpu/alu/U4177/ (63712). ABORTed.  
// Will add_iddq_exceptions for -int_float failure sites.  
...
```

analyze_scan_chains

Context: dft -scan

Mode: analysis

Distributes scan elements into new scan chains.

Usage

analyze_scan_chains [-force]

Description

This command distributes scan elements into new scan chains; scan elements identified as non-scannable are not considered for distribution. The scan modes and chain families defined using the [add_scan_mode](#) and [create_scan_chain_family](#) commands respectively control how the allocation of new chains is done. If not explicitly specified, the tool automatically defines a default unwrapped scan mode.

When allocating new scan chains, this command considers various scan element attributes, such as “is_non_scannable”, “clock_domain”, “clock_edge”, “class”, “cluster_name”, and “power_domain_name” along with implicit/explicit distribution constraints imposed by the [set_scan_insertion_options](#), [add_scan_mode](#), or [create_scan_chain_family](#) commands.

The resulting scan chain objects are themselves scan elements that can be introspected; they do not have their “exists” attribute set as they are not implemented in the netlist yet. These scan chains contain the distributed scan elements, but not the final required pipelining, retiming, or mode-enabling logic — that gets added when the [insert_test_logic](#) is invoked, once the distribution model is acceptable to the user.

Ensure that you specify the following commands in the following order:

1. Test point identification and analysis: [analyze_test_points](#)
2. X-bounding: [analyze_xbounding](#)
3. Wrapper analysis (as needed): [analyze_wrapper_cells](#)
4. Scan insertion: [analyze_scan_chains](#)

Arguments

- -force

When no scan modes have been defined, this optional switch deletes the results of previous wrapper cell analysis and infers a default unwrapped scan mode.

Examples

analyze_scan_chains

```
// Chain allocation of 'int_test' mode completed:  
//     14 distributed chains of sizes ranging from 12 to 13  
// Chain allocation of 'ext_test' mode completed:  
//     5 distributed chains of sizes ranging from 10 to 13  
...
```

report_scan_chains

analyze_simulation_mismatches

Context: patterns -scan

Mode: analysis

Analyzes simulation mismatches that occur between test patterns and a simulation performed by a specified external timing simulator.

Usage

```
analyze_simulation_mismatches {-AUto  
  | {-FAilure_file failure_file [-VCD_file vcd_filename]}  
  | {-MISmatches mismatch_bit... | Verilog_testbench_pathname}  
  [-Internal_patterns | -External_patterns]  
  {[-Simulation_script simulator_invoke_script] | [-MAnnual]}  
  [-SCan_test | -CHain_test | -ALl_test] [-HOST server_name] [-Lib lib_name]  
  [-TEstbench_for_vcd new_filename [-REplace]] [-SHift_check {ON | OFF}] [-VERbose]
```

Description

By default, the simulation VCD file, test patterns, and design data are all analyzed and the mismatch sources are identified. Once the analysis is complete, you can use Tessent Visualizer to graphically display the overlapping data and pinpoint the source of each mismatch.

Refer to “[Potential Causes of Simulation Mismatches](#)” in the *Tessent Scan and ATPG User’s Manual* for complete information.

Note

 All generated files are placed in the *work_dft_debug* directory inside your working directory. This directory is created if it does not already exist.

When using the `analyze_simulation_mismatches` command for a pattern with a P53 violation, the tool issues an error and stops the DRC checking:

```
// Error: P53 violation may produce incorrect "analyze simulation  
// mismatches" result.  
// Suggest to fix the test procedure timeplate to avoid P53.
```

The problem of the P53 error is due to an undefined clock waveform in the used timeplate. Refer to “[P53](#)” on page 3308 for additional information on resolving this issue.

Note

 The timestamp where the simulation actually fails does not match what this command reports, because the time `analyze_simulation_mismatches` command reports includes test setup to the beginning of the failing cycle.

Arguments

- **-AUto**

Required switch that automatically runs the entire simulation mismatch analysis on the currently loaded test patterns and design. This is the default behavior.

The top-level design and Verilog library must be compiled in your work directory prior to starting the simulation mismatch analysis. The tool searches for a “work” directory within the current working directory for these compiled files. Use the `-Lib` switch to specify a different directory.

The tool uses Questa Advanced Simulator as the Verilog simulator unless you specify a different simulator with the `-Simulation_script` switch.

- **`-FAilure_file` *failure_file***

Required switch and string pair that specifies the pathname to an existing failure file to use for the simulation mismatch analysis. Using this switch bypasses Stages 1 and 2 of the analysis.

`-VCD_file` *vcd_filename*

Optional switch and string that specifies the pathname of an existing simulation results VCD file for the mismatch analysis. This switch can only be used with the `-FAilure_file` switch. Using this switch bypasses the debug test bench simulation performed in Stage 4.

- **`-MISmatches` *mismatch_bit...***

Required switch and repeatable string that specifies a list of mismatches to analyze instead of using a failure file.

A *mismatch_bit* should be specified in one of the following formats:

fail_pattern_index chain_name cell_index

For example: “1 chain5 20” specifies the mismatch is on scan pattern 1, scan chain5, scan cell index 20.

fail_pattern_index PO_name

For example: “2 xyz” specifies the mismatch is on pattern 2 at PO signal xyz.

- **`Verilog_testbench_pathname`**

A required string that specifies the pathname of an existing Verilog test bench for the invocation of the old mismatch analysis. The tool performs an interactive communication with QuestaSim instead of dumping VCD data. This option only supports the Questa Advanced Simulator.

- **`-Internal_patterns`**

An optional switch that specifies the current internal pattern set for the mismatch analysis. This is the default.

- **-External_patterns**
An optional switch that specifies the currently loaded external pattern set for the mismatch analysis.
- **-Simulation_script *simulator_invoke_script***
An optional switch and string pair that specifies a simulation invocation script for the mismatch analysis. The script must invoke an external simulator and compile and simulate the test bench specified by the **-PAtterns** switch. By default, the analysis uses the simulator specified by the [set_external_simulator](#) command.
- **-MAnnual**
An optional switch to specify the “analyze simulation mismatch” functionality to stop at the step when the external Verilog simulator is needed. This option is useful when the Verilog simulation environment is complex and the simulation script cannot be written directly. When specifying the step, the tool stops after saving Verilog test bench and gives an instruction for what to do next to complete the mismatch debugging flow. See Example 6.

Note

Note that the **-MAnnual** and **-Simulation_script** switches are mutual exclusive.

- **-SCan_test**
An optional switch that specifies that the tool only analyzes scan patterns. This is the default.
- **-CHain_test**
An optional switch that specifies that the tool only analyzes chain patterns.
- **-All_test**
An optional switch that specifies that the tool analyzes both scan and chain patterns.
- **-Lib *lib_name***
An optional switch and string pair that specifies the pathname of the working simulation library. The working simulation library contains the compiled top-level design and any required parts libraries. By default, the tool uses the library named *work* in the same directory as the pattern test bench. For QuestaSim applications, you must use this switch to specify a different library whether or not you enter the **vlib** command.
- **-HOST *server_name***
An optional switch and string that specifies the name of a remote host on which to run the simulation portions of the mismatch analysis. The specified server must be accessible via **rsh**. For more information on **rsh** requirements, see “[Multiprocessing Requirements](#)” in the *Tessent Scan and ATPG User’s Manual*.
- **-TEstbench_for_vcd *new_filename***
An optional switch and string that specifies a filename for the debug test bench created in Stage 3 (default name *tessent_default.v_vcdtb.v*). The name of the simulation results VCD

file is derived from the name specified by this switch. The default VCD dump filename created from the debug test bench is *tessent_default.v_debug.vcd*

- -REplace

An optional switch that overwrites the *debug_testbench_filename* file if it already exists.

- -SHift_check {ON| OFF}

An optional switch and literal that enables checking for simulation mismatches that occur during the scan shift cycles. By default, the tool performs shift checking, but you might want to turn off this feature for performance reasons after you are sure that shift operation is working properly.

ON — Checks and reports if the scan shift cycle contains a mismatch between the Verilog simulation value and the ATPG expected value.

OFF — Analyzes mismatches only on the capture cycles.

- -VERbose

An optional switch that displays additional information about the simulation commands run in the background and the detailed mismatch data.

Examples

Example 1

The following example assumes the pathname of the QuestaSim bin directory is defined by the PATH variable and that patterns are generated but not yet saved. This example demonstrates the automatic simulation mismatch analysis flow—see “[Automatically Analyzing Simulation Mismatches](#)” in the *Tessent Scan and ATPG User’s Manual*.

The example first specifies the invocation command for the external simulator, then saves the generated pattern set. Next, it creates a Verilog library named *my_mismatch_work*, compiles the source for the top-level design and supporting simulation parts library into the library, and analyzes the simulation mismatches. Tessent Visualizer is invoked and displays the simulation, test pattern, and design data with the mismatch sources highlighted in red.

// 2 '/ix1278/Y' (238) scan-15 12900 0 1 0 incorrect library cell "and4"
// command: exit -d

```

Example 2

This example demonstrates using the `-failure_file` switch when you have previously done Verilog simulation. This example assumes you have run an initial simulation to verify test patterns, generated a failure file, and created a script to set up and run an external simulator on a separate server from the ATPG session. The following example runs a simulation mismatch analysis on the specified failure file using internal test patterns on a separate server.

analyze_simulation_mismatches -failure_file pat.fs.v.fail -simulation_script runsim

```

// Running script "runsim pat.fs.v.fail_vcdtb.v" from local host to create VCD file pat.fs.v.fail_debug.vcd.
// Debug 24 internal patterns, CPU time = 0.02 sec
...
// Step-5 Analyzing 24 internal scan patterns in parallel format.
// -----
// ID instance (gate_id) pattern-ix time (ns) seq_depth ATPG_val VCD_val mismatch_reason
// -----
// 1 '/ix1286/Y' (364) scan-1 1900 0 1 0 incorrect library cell "and4"
// 2 '/ix1278/Y' (265) scan-15 17300 0 1 0 incorrect library cell "and4"

```

For information on the output of this command, see the `report_mismatch_sources` command.

Example 3

This example shows the results of using the `-failure_file` and `-vcd_file` switches and shows a simulation script “`runsim`” for QuestaSim:

```
#!/bin/csh -f
#Expect netlist has been compiled to work directory, next line commented
#vlog ~/design/netlist.v -v ~/library/lib.v
vlog ${1}
vsim ${2} -c -do "run -all" -sdfmax /${2}/design_inst=~/design/good.sdf
```

Note that in the previous example, `${1}` is the Verilog test bench name. The simulation script is used twice, first for running the test bench with the initial pattern set to get the failing bits, and then a second run for the reduced test bench to get the VCD file. Therefore, the `vlog` script needs to take a parameter instead of fixed test bench name. The `${2}` is the Verilog test bench top instance name, which may change when the test bench name changes, so the name needs to be a parameter rather than a fixed name.

The following example uses the “`runsim`” script for automatic simulation mismatch analysis. Assume that the design and Verilog library have been compiled in advance in the work directory. After creating patterns, run the following command:

analyze_simulation_mismatches -simulation_script runsim

```
// Running script "runsim work_dft_debug/tessent_default.v_vcdtb.v" from local host to create VCD file
work_dft_debug/tessent_default.v_debug.vcd.
...
// -----
// Step-5 Analyzing 24 internal scan patterns in parallel format.
// -----
// ID instance (gate_id) pattern-ix time (ns) seq_depth ATPG_val VCD_val mismatch_reason
// -----
// 1 */ix1286/Y' (364) scan-1 1900 0 1 0 incorrect library cell "and4"
// 2 */ix1278/Y' (265) scan-15 17300 0 1 0 incorrect library cell "and4"
```

Example 4

The following example shows a simulation script for NCVerilog:

```
#!/bin/csh -f
ncsdfc ../data/good.sdf
#Expect netlist to be compiled, next line commented out
#ncvlog ~/design/netlist.v -v ~/library/lib.v
ncvlog ${1}

#The following two commands create sdfcmdfile for ncelab to load SDF file
echo 'COMPILED_SDF_FILE = "~/design/top.sdf.X",' >! sdfcmdfile
echo "SCOPE = ${2}.design_inst;" >> sdfcmdfile
ncelab worklib.${2}:module -sdf_cmd_file sdfcmdfile
ncsim worklib.${2}:module
```

Example 5

The following example shows how to run a simulation analysis on a remote host.

analyze_simulation_mismatches -auto -host flea01 -simulation_script runsim

```
// Simulation mismatch source is deleted.
// Running script "runsim tessent_default.v_vcdtb.v" from host01 to create VCD file tessent_default.v_debug.vcd.
// Debug 25 internal patterns, CPU time = 0.02 sec
...
// -----
// ID instance (gate_id) pattern-ix time (ns) seq_depth ATPG_val VCD_val mismatch_reason
// -----
// 1 '/ix1286/Y' (364) scan-1 1900 0 1 0 incorrect library cell "and4"
// 2 '/ix1278/Y' (265) scan-15 17300 0 1 0 incorrect library cell "and4"
```

Example 6

The following example shows using the **-MANual** switch:

analyze_simulation_mismatches

```
// -----
// Step-1 Creating Verilog test bench work_dft_debug/tessent_default.v
// with failure file dump.
// -----
// Manual flow is specified by user. Please simulate Verilog test bench
// work_dft_debug/tessent_default.v to create failure file
// work_dft_debug/tessent_default.v.fail.
// Then, "analyze simulation mismatch -fail
// work_dft_debug/tessent_default.v.fail" to generate reduced test bench
// with VCD dump.
```

Upon completion of this step, take the Verilog test bench *work_dft_debug/tessent_default.v* and perform the Verilog simulation to product the failure file *tessent_default.v.fail*.

Then, you run the following command:

analyze_simulation_mismatches -fail work_dft_debug/tessent_default.v.fail -manual

```
// -----
// Step-1 Loading failure file work_dft_debug/tessent_default.v.fail.
// -----
// Step-2 Creating Verilog test bench
// work_dft_debug/tessent_default.v.fail_vcdtb.v with VCD dump.
// -----
// Manual flow is specified by user. Please simulate Verilog test bench
// work_dft_debug/tessent_default.v.fail_vcdtb.v to create VCD file
// work_dft_debug/tessent_default.v.fail_debug.vcd.
// Then, "analyze simulation mismatch -fail
// work_dft_debug/tessent_default.v.fail -vcd
// work_dft_debug/tessent_default.v.fail_debug.vcd" to complete the
// analysis.
```

After this step, take the Verilog test bench *work_dft_debug/tessent_default.v.fail_vcdtb.v* and perform the Verilog simulation to product the VCD dump file *work_dft_debug/tessent_default.v.fail_debug.vcd*.

Finally, you use the following command to complete the task:

```
// -----  
// Step-1 Loading failure file work_dft_debug/tessent_default.v.fail.  
// -----  
// Step-2 Loading VCD file work_dft_debug/tessent_default.v_debug.vcd.  
// -----  
// Step-3 Analyzing 2 internal scan patterns in parallel format.  
// -----  
// ID instance (gate_id) pattern-ix time (ns) seq_depth ATPG_val VCD_val mismatch_reason  
// -----  
// 1 '/u102/' (124) scan-10 2100 0 1 0 incorrect loading during the main shifts
```

[write_patterns](#)

[set_external_simulator](#)

analyze_test_points

Context: dft -test_points

Mode: analysis

Specifies the test points analysis and generates a list of test points to be inserted by the tool.

Usage

analyze_test_points

Description

If you want to manually add test points before performing the test point analysis, you can do so using the [add_control_points](#) and the [add_observe_points](#) commands. You must do this prior to issuing the `analyze_test_points` command. Use the [delete_test_points](#) command to remove these manually added test points if you do not want the test points to be considered during analysis.

Note

 When you have generated a list of test points with the `analyze_test_points` command, then these test points have to be deleted before you can modify the locations where test points are permitted. Any existing test points need to be deleted before issuing the [add_notest_points](#) and [delete_notest_points](#) commands.

Note

 Not all gates in the design are considered by the tool for inserting test points. For various reasons test points are not inserted on gates in the clock tree or in the scan path, gates in protected blocks, or gates where the user has explicitly requested that no test points should be inserted using the `add_notest_points` command. If there are many locations where test points cannot be inserted the tool may not be able to find the best locations for test points. This may increase the number of test points that is needed to reach the fault coverage target. Therefore, if test points cannot be inserted at more than 20 percent of the gate-pins the tool generates a warning. The warning specifies the number of these locations as well as the main reason(s) why test points cannot be inserted at these locations.

There are three distinct purposes for using test points: to improve logic_bist random test coverage, to improve ATPG test coverage or to reduce ATPG pattern counts. The type of test point analysis performed depends on the setting of the `set_test_point_type` command, the default being `edt_pattern_count`. For more information, see “[Why You Use Test Points](#)” in the *Tessent Scan and ATPG User’s Manual*.

One typical usage of the test point analysis capability is to identify LBIST test points that improve fault coverage when applying pseudo-random patterns. This means the analysis is based on the entire population of stuck-at faults within the design. An alternate use of the LBIST test point analysis algorithm is to identify test point locations that may improve fault coverage when creating and applying deterministic patterns. For example, you could choose to load a fault list that is based on faults that are left undetected (AU, UC, UO, PT or PU) after

performing ATPG. Targeting these fault locations identifies test points that improve the probability of detecting these faults, and this might enable the tool to create ATPG patterns that successfully target these faults. For more information, see “[Test Points for Improving the Test Coverage of Deterministic Patterns](#)” in the *Tessent Scan and ATPG User’s Manual*.

Ensure that you specify the following commands in the following order:

1. Test point identification and analysis: `analyze_test_points`
2. X-bounding: `analyze_xbounding`
3. Wrapper analysis (as needed): `analyze_wrapper_cells`
4. Scan insertion: `analyze_scan_chains`

Arguments

None

Examples

Example 1

The following example specifies that a maximum number of 50 test points are to be generated for a design that is tested with a set of 30000 random patterns. Then it performs the test points analysis based on these specifications. After the test points are reported to the screen they are inserted into the netlist:

```
set_system_mode analysis  
set_test_point_analysis_options -total_number 50 -pattern_count_target 30000  
analyze_test_points  
report_test_points  
insert_test_logic
```

Example 2

The following example generates 50 test points and performs the test point analysis. The test points are reported to the screen but are then deleted without being inserted as they were only generated for reporting purposes. It then sets the attribute `no_control_point` to true for `block1` and again performs test point analysis. After the test points are reported to the screen they are inserted into the netlist.

```
set_system_mode analysis  
set_test_point_analysis_options -total_number 50 -pattern_count_target 30000

analyze_wrapper_cells

Context: dft -scan

Mode: analysis

Identifies shared and dedicated wrapper cells for the primary I/O ports.

Usage

```
analyze_wrapper_cells [-force | -reset]
```

Description

This command launches the identification of the shared wrapper cells for the primary I/O ports that can be controlled with the `set_wrapper_analysis_options` command. The user-specified clocks and scan-related I/O ports are automatically excluded from identification. The wrapper cells identified for the primary I/O ports are stitched into the wrapper chains. If the `set_wrapper_analysis_options` command was not run, the `analyze_wrapper_cells` command performs the default wrapper cells identification similar to running the `set_wrapper_analysis_options` command with no arguments.

When the `analyze_wrapper_cells` command is used in conjunction with the `set_dedicated_wrapper_cell_options` command, the wrapper cells analysis results in registration of the specified primary I/O ports or the primary I/O ports that have failed the shared wrapper cells identification with the dedicated wrapper cells to guarantee better test coverage of the circuit. This means that new scan cells are added to all specified and failed primary I/O ports during scan insertion, subject to certain design considerations. The dedicated wrapper cells added to the primary I/Os are stitched into the wrapper chains. Note that if there are pad cells on primary ports, the tool inserts dedicated wrapper cells at the core side of the pad cells.

When you use the `set_wrapper_analysis_options` command, with or without the `set_dedicated_wrapper_cell_options` command, the identification includes the identification of existing sequential elements accessible via combinational logic from primary inputs or primary outputs as input/output registration cells (that is, shared wrapper cells). Thus, a shared wrapper cell serves a dual purpose of both functional mode, as well as the control and observe function during test. The advantage of shared wrapper cells is that less logic must be added and the external test mode (ExTest) can test the timing of the actual path.

`Analyze_wrapper_cells` may invalidate data from other analysis stages. Use this command before any scan chain analysis. If you have already completed scan chain analysis when you enter the `analyze_wrapper_cells` command, it results in an error. You can use the `-force` switch to override it, in which case the results of scan chain analysis are reset, and you must repeat it to recreate the scan modes and scan chain families you want.

The [report_wrapper_cells](#) command reports information about the identified wrapper cells for each primary I/O port subjected to wrapper cell identification.

Ensure that you specify the following commands in the following order:

1. Test point identification and analysis: `analyze_test_points`
2. X-bounding: `analyze_xbounding`
3. Wrapper analysis (as needed): `analyze_wrapper_cells`
4. Scan insertion: `analyze_scan_chains`

Arguments

- `-force`

An optional switch that directs the tool to forcefully run the `analyze_wrapper_cells` command. To avoid using invalidated data, the tool deletes all the scan modes and scan chain families. You must recreate the scan modes and scan chain families as needed after you run the `analyze_wrapper_cells` command.

- `-reset`

An optional switch that deletes the results of wrapper analysis, resets the `wrapper_type` attributes and removes information about dedicated wrapper cells

Examples

The following example illustrates the use of the `analyze_wrapper_cells` command:

set_dedicated_wrapper_cell_options on -ports out3 analyze_wrapper_cells

Port information and user constraints:

Input ports:	4 total,	1 ignored,	0 excluded,	0 off,	0 on,	3 auto
Output ports:	3 total,	0 ignored,	0 excluded,	0 off,	1 on,	2 auto

Wrapper analysis summary:

- 1 output port required a dedicated wrapper cell.
- 1 input port required a dedicated wrapper cell.
- 1 flip-flop was converted into an output shared wrapper cell.
- 3 flip-flops were converted into input shared wrapper cells.

Use `report_wrapper_cells` for more details.

report_wrapper_cells -verbose

```
-----

- [set_wrapper_analysis_options](#)

analyze_xbounding

Context: dft -scan

Mode: analysis

Performs X-bounding analysis.

Usage

analyze_xbounding [-force]

Description

This command is used to identify memory elements (current scan cells or cells that will be converted to scan-in a subsequent run) that might capture an unknown value during Logic BIST. In addition, the command identifies where to place bounding muxes that prevent these X-sources from reaching the memory elements and corrupting the signature during Logic BIST.

The X-bounding analysis uses the E5 DRC to identify and bound all X sources from reaching scan cells and corrupting the MISR. All primary inputs and internal X source pins (for example, non scan cells, blackbox outputs pins) are x-bounded.

The X-bounding analysis uses the E9 DRC to identify wire gates that may be driving a net to opposing values (contention). The tool does not add hardware to avoid the contention, however it adds X-bounding logic to prevent observation of the wire gates with the E9 violation.

The X-bounding analysis uses the E10 DRC to detect tristate bus contention. The tool does not add any hardware to avoid the bus contention, however it adds X-bounding logic to prevent observation of the bus with the E10 violation.

The X-bounding analysis uses the E11 DRC to detect a bus that can attain a Z-state. The tool does not add any hardware to prevent the bus from reaching the Z state, however it adds X-bounding logic to prevent observation of the floating bus.

The X-bounding process depends on pin constraints on the primary input pins to indicate them as X sources. These X-constraints are implicitly enforced by this command, but can also come from existing input constraints. When a pin is explicitly constrained to either 0 or 1, it is not treated as an X source.

The mux and scan cell library models used for X-bounding can be specified using the `cell_type` attribute in the Tessent Cell library or by the [add_cell_models](#) command. If any of the required library cell models are not specified, an error message is reported.

The `analyze_xbounding` command also marks as notest points the previously observable gate pins that are on the input side of the X-bounding muxes. In addition, an X-source that does not feed into any scannable flops (for example, it simply connects to a primary output pin) is not bounded. Any previously observable gate-pins that are driven by that X-source are also marked as notest points.

Note

 You must issue this command to perform X-bounding analysis. The tool does not automatically perform the analysis when you issue the `insert_test_logic` command.

Analyze_xbounding may invalidate data from other analysis stages. This command should be used before any wrapper analysis or and scan chain analysis. If you have already completed any of these steps when you issue the analyze_xbounding command, it results in an error. You can use the `-force` switch to override it, in which case the results of wrapper analysis and scan chain analysis are reset and you must repeat them.

The X-bounding analysis also bounds false and multi-cycle paths. This capability is triggered by reading an SDC file prior to issuing the command. The tool identifies any scannable flops that could capture an X due to a user-defined false or multi-cycle path. The tool adds X-bounding logic that blocks the path at the D-input of the destination of the flop. These flops “capture” the inverted value of the flop output so they can still trigger transitions at the output during launch-of-capture transition fault testing.

Ensure that you specify the following commands in the following order:

1. Test point identification and analysis: `analyze_test_points`
2. X-bounding: `analyze_xbounding`
3. Wrapper analysis (as needed): `analyze_wrapper_cells`
4. Scan insertion: `analyze_scan_chains`

Arguments

- `-force`

An optional switch that directs the tool to forcefully issue the `analyze_xbounding` command. In order to avoid using invalidated data the tool resets the results of wrapper analysis and deletes all the scan modes and scan chain families before doing X-bounding. It is recommended that you re-run wrapper analysis and set the scan modes and scan chain families as needed before you issue the `analyze_xbounding` command.

Examples

This example transitions from setup to analysis mode, triggers the X-bounding analysis, and then reports the locations of the X-bounding muxes:

```
set_system_mode analysis
analyze_xbounding
report_xbounding -verbose
```

annotate_diagnosis

Context: patterns -scan_diagnosis

Mode: analysis

Adds DFM and RCD data, if available, to existing diagnosis reports.

Usage

annotate_diagnosis *directory_path* [-force] [-verbose] [-report] [-regex *regular_expression*]

Description

You can add RCD constants to existing diagnosis reports using the `annotate_diagnosis` command. To annotate a diagnosis report, you must load the same pattern set that you used to run `diagnosis` and create RCD constants.

If there is already a DFM rule of the same name and type in the report, the tool replaces it. If there are already existing RCD feature statistics in the report, the tool replaces them.

The tool also checks the design/patterns MD5s in the `ALL_FAILURE_INFO` section of each diagnosis report to match the currently loaded design and patterns. Annotation fails if these do not match.

Note

 The `set_diagnosis_options -include_dfm_rules` and `-include_rcd_constants` switches do not affect the annotation process. Information is always preserved or added in the annotated diagnosis reports based on the content of the VDB or LDB that is open.

Arguments

- ***directory_path***
A required string that specifies the directory path of a diagnosis report.
- **-force**
An optional switch that specifies to bypass any issues with MD5 compatibility that arise.
- **-verbose**
An optional switch that specifies to report all MD5 mismatch warnings during the `annotate_diagnosis` run.
- **-report**
An optional switch that specifies to report a cumulative summary report of MD5 mismatch warnings during the `annotate_diagnosis` run.

- `-regexpr regular_expression`

An optional switch that specifies to match the diagnosis reports to the specified `regular_expression`. If this switch is not specified, the following extensions are automatically skipped:

`swp .adb .ldb .csv .lay .json .tcl .pl .sh .csh .do .db .verify`

Examples

Example 1

The following example adds the RCD constants to the `failure_file_directory` diagnosis report.

```
read_flat_model flat_model.gz  
read_patterns pattern_file.gz  
open_layout ldb_directory  
annotate_diagnosis failure_file_directory
```

Example 2

The following example shows how to add RCD constants to existing diagnosis reports. Use the [read_patterns](#) command to specify the applicable pattern set.

```
# Specify the same pattern set that was used to run diagnosis  
# and create RCD constants  
  
read_patterns /src/patterns.ascii  
  
# Open the LDB  
  
open layout design.dft.ldbannotate_diagnosis small_diags_rcd_gz
```

Related Topics

[delete_dfm](#)

[import_dfm](#)

append_to_collection

Context: unspecified, all contexts

Mode: all modes

Adds one or more objects to a collection referenced by the specified *var_name*.

Usage

```
append_to_collection var_name obj_spec [-unique]
```

Description

The `append_to_collection` command appends all elements in *obj_spec* to the collection referenced by the variable *var_name*. If the variable does not exist, the variable is created and made to point to a collection with elements from *obj_spec* as its value. An error is generated if the variable exists and does not reference a collection.

The result of the `append_to_collection` command is either a modification of the collection that was initially referenced by *var_name* or a new collection if the variable did not exist.

The `append_to_collection` command provides the same semantics as the [add_to_collection](#) command but with significant performance improvement. If you are building up a collection in a loop, using the `append_to_collection` command is more efficient as shown in “[Example 2](#)” on page 470.

Arguments

- *var_name*
A required value that specifies a Tcl variable name. The objects matching *obj_spec* are added to the collection referenced by this variable.
- *obj_spec*
A required value that specifies a Tcl list of one or more object names or a collection of one or more objects to append to the collection referenced by *var_name*. The *obj_spec* can be an empty collection.
- `-unique`
An optional switch that prevents duplicate objects from being appended to the collection. By default, duplicate objects are not removed.

Examples

Example 1

The following example appends a collection referenced by variable *b* to collection referenced by variable *a*.

```
set a [get_ports a*]  
set b [get_ports b*]  
append_to_collection a $b
```

Example 2

The following example creates a collection of all nets connected to pins of design instances matching `u1/myPrefix*`. Note that using the `-unique` option automatically removes duplicate nets. This example is the same as the example shown for the [add_to_collection](#) command. Using the `append_to_collection` command for such an application is recommended and is much more efficient.

```
foreach_in_collection inst [get_instances u1/myPrefix* -of_type design] {  
    set inputs [get_pins -of_instance $inst -direction input]  
    set outputs [get_pins -of_instance $inst -direction output]  
    append_to_collection sum [get_fanins $inputs -stop_on net] -unique  
    append_to_collection sum [get_fanouts $outputs -stop_on net] -unique  
}
```

apply_specification_defaults

Context: dft, patterns

Mode: all modes

Automatically applies all defaults specified in the DefaultsSpecification/DftSpecification and DefaultsSpecification/PatternsSpecification wrappers to wrappers that were created manually.

Usage

```
apply_specification_defaults [id] [-design_name design_name]  
    [-config_object config_object]
```

Description

You must use this command to apply the defaults under the following circumstances:

- When a DftSpecification or PatternsSpecification has been created manually.
- When a DftSpecification or PatternsSpecification has been modified after the specification has been created and the new defaults should be applied.

You can also use this command when creating a [DftSpecification](#) wrapper in the Configuration Data window. You do not need this command when using the [create_dft_specification](#) command because the create_dft_specification command automatically applies the specified defaults while creating the DftSpecification wrapper.

Similarly, you can also use this command when creating a [PatternsSpecification](#) wrapper in the Configuration Data window. You do not need this command when using the [create_patterns_specification](#) command because the create_patterns_specification command automatically applies the specified defaults while creating the PatternsSpecification wrapper.

Note

 Note that you may need to use the apply_specification_defaults command to re-apply the defaults when the specification or the “defaults” have been modified *after* the wrappers have been created.

Arguments

- *id*

An optional string that specifies the specification wrapper that is to be processed. As described in the DftSpecification and PatternsSpecification wrapper syntax, the wrapper is identified by the two strings: *design_name* and *id*. If you only have one DftSpecification or PatternsSpecification wrapper present in memory that matches *specification*(*design_name*,*), you can omit the *id* from the [process_dft_specification](#) or [process_patterns_specification](#) command. However, if several DftSpecification or PatternsSpecification wrappers matching *specification*(*design_name*,*) exist in memory, you must specify the appropriate *id* when executing the [process_dft_specification](#) or

[process_patterns_specification](#) command. Refer to the `-design_name` option to understand how the `design_name` value is obtained.

- `-design_name` *design_name*

An optional switch and string pair that specifies the *design_name* value used to identify the `DftSpecification` or `PatternsSpecification` wrapper. The `-design_name` value defaults to the current design if it has been set with the [set_current_design](#) command. If the current design has not been set, it is extracted from the `DftSpecification` or `PatternsSpecification` wrapper existing in memory.

When the *id* is specified, if exactly one wrapper matches “*specification (*,id)*” in memory, the *design_name* is extracted from the `design_name` parameter of the `DftSpecification` or `PatternsSpecification` wrapper; if more than one wrapper matches, the `-design_name` must be specified.

When the *id* is not specified, if exactly one wrapper matches “*specification (*,*)*” in memory, the *design_name* is extracted from the `design_name` parameter of the `DftSpecification` or `PatternsSpecification` wrapper; if more than one wrapper matches, the `-design_name` must be specified.

- `-config_object` *config_object*

An optional switch and string pair that specifies

An optional switch and string pair that applies the defaults to only one specific `DftSpecification` or `PatternsSpecification` wrapper. By default all the specifications in memory that correspond to the selected *id* and “`-design_name` *design_name*” are processed.

Examples

Example 1

The following example calls the `apply_specification_defaults` command on a `DftSpecification` wrapper that was created manually to get the specified defaults found in the [DefaultsSpecification/DftSpecification](#) wrapper applied to the `DftSpecification` wrapper.

```
apply_specification_defaults
```

Example 2

The following example uses the `apply_specification_defaults` to reapply defaults to the `DftSpecification` after the specification has been created.

```
set_context dft -rtl
set_tsdb_out_dir tsdb_outdir_test_read
read_verilog chip.vb
set_current_design chip
set_design_level sub_block
set_system_mode analysis
set_defaults_value \
  DftSpecification/IjtagNetwork/HostScanInterface/Chip/tck chip_tck
set_defaults_value \
  DftSpecification/IjtagNetwork/HostScanInterface/Block/tck block_tck

read_config_data -from_string {
  DftSpecification(chip,rtl) {
    IjtagNetwork {
      HostScanInterface(ijtag) {
        Tap(TAP1) {
          }
        }
      }
    }
  }
}

apply_specification_defaults

set_top [get_config_element DftSpecification]
report_config_data $top
process_dft_specification
extract_icl
```

assert_icl_sib

Context: patterns -silicon_insight -ijtag

Mode: setup

Configures the specified SIB to pick one of the host inputs.

Usage

```
assert_icl_sib sib_name [-host_index num_host_interfaces]
```

Description

Use this command when you are configuring a scan path in the IJTAG network. The specified SIB is active in the scan path.

Use this command when manually debugging IJTAG networks as described in “[Diagnosing and Debugging IJTAG Networks](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

If the specified SIB has more than one host interface, you must specify the -host_index switch.

Arguments

- *sib_name*
A required variable that specifies the name of the SIB that you want to assert to a 1 state.
- -host_index *num_host_interfaces*
An optional switch and variable pair that specifies the number of host interfaces the specified SIB has. The host interfaces correspond to input indices starting at the number 1. 0 is reserved for the client interface.

Examples

```
assert_icl_sib sib_I4
```

```
assert_icl_sib sib_I4 -host_index 0
```

catch_output

Context: unspecified, all contexts

Mode: all modes

Runs the specified tool command line, and may be used to prevent command errors from aborting the enclosing dofile or Tcl proc.

Usage

catch_output *cmdline* [-output *output_variable*] [-result *result_variable*] [-tee]

Description

This command returns 0 if the embedded command succeeds, and 1 if it fails.

You can use the -output switch to specify a variable to contain all of the output of the embedded command. You can use the -result switch to specify a variable to contain the Tcl result of the embedded command if the command returns one.

Arguments

- *cmdline*
A required string enclosed in braces “{ }” that specifies the command and associated arguments whose output you want to capture. The command is typically a report_* command. A return value of 1 indicates the command failed; a return value of 0 indicates the command succeeded.
- -output *output_variable*
An optional switch and variable name that is set to the value of the entire command output.
- -result *result_variable*
An optional switch and variable name that specifies to write the Tcl result returned by the embedded command to the *result_variable* variable.
- -tee
An optional switch that specifies to write the command output to the transcript and to a logfile.

Examples

Example 1

The following example writes the result of the get_gate_pins command to the variable oVar; the result can be an error message if the command fails. If get_gate_pins fails, catch_output returns 1, and the “if” wrapper commands are run.

The example also assigns the Tcl result returned by the get_gate_pins command to the rVar variable; the result is a collection if the command succeeds. If get_gate_pins succeeds, the catch_output command returns 0, and the “else” wrapper commands are run.

The dofile continues even if the `get_gate_pins` command fails. Nothing is reported to the transcript.

```
if {[catch_output {get_gate_pins foo*} -output oVar -result rVar]} {  
  # commands when get_gate_pins fails  
} else {  
  # commands when get_gate_pins succeeds  
}
```

Example 2

The following example uses the `catch_output` command to capture the output of a tool command in a variable.

```
set retVar [catch_output {report_gate /gate3} -output resultA -tee]
```

```
// /gate3  nor02  
//      A0      I  /gate2/Y  
//      A1      I  /ff2/Q  
//      Y      O  /ff5/D  ff4/D  ff3/D  gate6b/E
```

```
If { $retVar == 0 } {  
  puts $resultA  
}
```

```
// /gate3  nor02  
//      A0      I  /gate2/Y  
//      A1      I  /ff2/Q  
//      Y      O  /ff5/D  ff4/D  ff3/D  gate6b/E
```

check_design_rules

Context: dft, patterns

Mode: setup

Transitions the tool from setup mode to analysis mode.

Usage

check_design_rules

Description

Causes the tool to transition from setup mode to analysis mode.

In RTL context, the design is synthesized in parts before creating the flat model. The DRC rules specific to the current context are then run. If no DRC with a severity of error fails, the tool enters analysis mode.

If any DRC with a severity of error fails, the tool remains in setup mode, which enables you to analyze the DRC violation and either add more definitions (such as clocks) or make edits to your circuit.

Arguments

None

Examples

The following example shows the results of calling the check_design_rules command, which generates a DRC violation. The violation is fixed by defining a missing clock. The check_design_rules command is then re-issued and successfully transitions from system mode to analysis mode.

```
SETUP> check_design_rules
```

```
// -----
// Begin RTL synthesis.
// -----
// Module 'sub_block1' synthesized.
// Module 'block1' synthesized.
// RTL synthesis completed, synthesized modules=2, Time=1.88 secs.
// -----
// -----
// Begin RTL synthesis.
// -----
// Module 'my_clock_gate' synthesized.
// Module 'my_inv' synthesized.
// RTL synthesis completed, synthesized modules=2, Time=1.94 secs.
// -----
// -----
// Begin RTL synthesis.
// -----
// Module 'my_clock_mux' synthesized.
// RTL synthesis completed, synthesized modules=1, Time=1.84 secs.
// -----
// Warning: Rule FP2 violation occurs 1 times
// Flattening process completed, cell instances=82, gates=843, PIs=5,
// POs=0, CPU time=0.01 sec.
// -----
// Begin circuit learning analyses.
// -----
// Learning completed, CPU time=0.00 sec.
// Error: The memory clock pin 'sub_block1_i1/mem1/CLK' (67.40) source
// tracing stopped at pin 'pll/vco' (9.0).
// Correct the blocking conditions or use the 'add_clocks -period' if
// this is an embedded oscillator or
// add_clocks -reference' if this is an active PLL or clock divider.
// (DFT_C1-1)
// Error: There was 1 DFT_C1 violation (Memory clock not properly sourced
// by a declared clock).
```

SETUP> add_clocks pll/vco -reference pll/ref -freq_mult 10 -freq_divider 2

```
// Warning: Flat model deleted.
```

SETUP> check_design_rules

```
// Warning: Rule FP2 violation occurs 1 times
// Flattening process completed, cell instances=82, gates=844, PIs=6,
// POs=0, CPU time=0.01 sec.
// -----

// -----
// Learning completed, CPU time=0.00 sec.
```

ANALYSIS>

check_synthesis

Context: all contexts

Mode: all modes

Checks the status of synthesis that was previously launched by the `run_synthesis` command.

Usage

```
check_synthesis [-design_name design_name] [ -design_id design_id] [-report_status  
| -get_status_dictionary | -wait | -kill] [-synthesis_output_directory_list directory_list]
```

Description

Checks the status of synthesis run that was previously launched by the [run_synthesis](#) command.

Based on the specified option, you can generate a report, get a status dictionary, or get the pass or fail status.

Arguments

- `-design_name design_name`
An optional switch and value pair that specifies the design name to which `run_synthesis` is associated with. By default, the name of the *current_design* is used when it is set. If you run the command immediately after running the [process_dft_specification](#) command, you do not need to specify this option.
- `-design_id design_id`
An optional switch and value pair that specifies the *design_id* to which `run_synthesis` is associated with. By default, the name of the *current_design_id* is used when it is set. If you run the command immediately after running the `process_dft_specification` command, you do not need to specify this option.
- `-report_status`
An optional switch that is mutually exclusive with the `-get_status_dictionary` and `-wait` options. When none of the these options is specified, `-wait` is assumed. By default, `-report_status` includes all the *design_ids* found in the synthesis directories specified by `-synthesis_output_directory_list`.
- `-get_status_dictionary`
An optional switch that is mutually exclusive with `-report_status` and `-wait`. When none of these options is specified, `-wait` is assumed.

The Tcl dictionary returned with `-get_status_dictionary` contains all the information that was gathered to produce the report generated when `-report_status` is used instead.
- `-wait`
An optional switch that waits for synthesis task to be completed before returning with a completion message. When running in interactive mode, the command reports a status line

that is updated every second showing at what stage synthesis is current operating, which can be unscheduled, queued, running, pass, or fail, as shown in Example 1.

- **-kill**
An optional switch that kills the selected running synthesis. The **-kill** switch is mutually exclusive with **-report_status**, **-get_status_dictionary** and **-wait**. If no switch is specified, **-wait** is assumed.
- **-synthesis_output_directory_list *directory_list***
An optional switch and value pair that specifies a list of directories that contain the *design_name_design_id.synthesis_synthesis_tool* directories. The default value is *./synthesis_outdir*. You can configure the default value using the “**set_run_synthesis_options -synthesis_output_directory**” command and option

Examples

The following examples show the results of using **check_synthesis** with the available options.

Example 1

```
SETUP> check_synthesis
```

```
unscheduled 0 queued 0 running 0 pass 1 fail 0
// The 17 synthesized files listed in
// './synthesis_outdir/blockB_rtl.synthesis_dc_shell/file_list' were
// copied to the current tsdb output directory.
```

Example 2

```
SETUP> check_synthesis -get_status_dictionary
```

```
// ./synthesis_outdir {blockB_rtl {status pass date {Mon Aug 24 13:02:38
// PDT 2015} sub_dir blockB_rtl.synthesis_dc_shell log_file
// dc_shell.synthesis_log errors_count 0 errors {}}}
```

Example 3

```
SETUP> check_synthesis -synthesis_output_directory_list \
synthesis_outdir
```

```
unscheduled 0 queued 0 running 0 pass 1 fail 0
// The 17 synthesized files listed in
// 'synthesis_outdir/blockB_rtl.synthesis_dc_shell/file_list' were copied
// to the current tsdb output directory.
```

Example 4

The following example shows **check_synthesis** usage to report the synthesis status for all *design_ids* in the synthesis output directories named “**check_out_ut1**” and “**check_out_ut2**” for design “**chip**”:

```
SETUP>check_synthesis -design_name chip -report \
-synthesis_output_directory_list [list check_out_ut2 check_out_ut1]
```

check_synthesis

```
// Synthesis status for check_out_ut2/chip_rtl.synthesis_dc_shell
// =====
// -----
// Name      Status  Errors  Date
// -----
// chip_rtl  pass    0       Mon Feb 08 09:05:08 PST 2016
//

// Synthesis status for:
// (1) check_out_ut1/chip_rtl.synthesis_dc_shell
// (2) check_out_ut1/chip_rtl2.synthesis_dc_shell
// =====
// -----
// Name      Status  Errors  Date
// -----
// (1) chip_rtl  fail    3       Thu Feb 04 11:25:49 PST 2016
// (2) chip_rtl2 pass    0       Mon Feb 08 09:05:08 PST 2016
//
```

check_testbench_simulations

Context: dft, patterns

Mode: all

Checks the status of simulations that were previously launched by the `run_testbench_simulations` command.

Usage

```
check_testbench_simulations
  [-design_name design_name]
  [-design_id design_id]
  [-pattern_id pattern_id]
  [-select pattern_list]
  [-exclude pattern_list]
  [-report_status | -get_status_dictionary
  | -kill | -wait [-keep_simulation_data {on | off | on_failure}]]
  [-simulation_output_directory_list simulation_output_directory_list]
  [-simulator {questa | vcs | incisive}]
```

Description

Checks the status of simulations that were previously launched by `run_testbench_simulations` command.

Based on the specified option, you can generate a report, get a status dictionary, or get the pass or fail status. You can also kill pending simulations or delete patterns simulation directories.

Arguments

- `-design_name design_name`

An optional switch and value pair that specifies the `design_name` that the patterns to check are associated with. By default, the name of the `current_design` is used when it is set. The `design_name` is part of the `design_name_design_id.simulation_pattern_id` directory name that contains the simulation results.

- `-design_id design_id`

An optional switch and value pair that specifies the `design_id` to that the patterns to check are associated with. By default, the `design_id` value set using the `design_name_design_id.simulation_pattern_id` directory name that contains the simulation results.

A `design_id` must only use a combination of the following characters:

- Alphabetic, both uppercase and lowercase. For example: “abc”, “ABC”, “AbC”, and so on.
- Numeric. For example: “123”.

- Underscore. For example: “A_1”.

- **-pattern_id** *pattern_id*

An optional switch and value pair that specifies the *pattern_id* that the patterns to simulate are associated with. By default, the *pattern_id* used by the previously run [process_patterns_specification](#) command is reused automatically; otherwise, the default value of “signoff” is used.

The *pattern_id* is part of the *design_name_design_id.simulation_pattern_id* directory name that contains the simulation results.

- **-select** *pattern_list*

An optional switch and value pair that restricts the action on a list of *pattern_name.simulation[_simulation_id]* directories that match at least one of the entries in the *pattern_list*. The name patterns are simple glob patterns with * as the wild card. Refer to [Example 2](#).

- **-exclude** *pattern_list*

An optional switch and value pair that excludes a list of *pattern_name.simulation[_simulation_id]* directories that match at least one of the entries in the *pattern_list* from the action of the command. The name patterns are simple glob patterns with * as the wild card. Refer to [Example 3](#).

- **-report_status**

An optional switch that is mutually exclusive with the **-get_status_dictionary**, **-kill**, and **-wait** options. When none of these options are specified, **-wait** is assumed. When you use the **-report_status** switch, the command creates a report listing the simulation status of each pattern found inside the *design_name_design_id.simulation_pattern_id* directories located inside one of the *simulation_output_directory_list* directories that was simulated, is still simulating, or is waiting to be simulated. You can restrict the report can to a subset of the *pattern_name.simulation[_simulation_id]* directories by using the **-select** or the **-exclude** options.

The format of the report is illustrated here. The date entry shows the time the current status was achieved. The missing miscompares column is for negative testing where the [run_testbench_simulations](#) **-expected_miscompare_count** option was used or a *simulator.simulation_log_reference* file was present in the directory.

```
// Simulation status for <simulation_output_directory>
// =====
// -----
// Pattern Name                Status          Unexpected      Missing   Date
// -----
// <pattern_name> (<sim_id>)    unscheduled
// <pattern_name> (<sim_id>)    queued
// <pattern_name> (<sim_id>)    running
// <pattern_name> (<sim_id>)    pass           0              0          Wed Oct 08
//                               23:38:32 GMT 2014
// <pattern_name> (<sim_id>)    fail           2              0          Wed Oct 08
//                               23:39:40 GMT 2014
```

After issuing the `run_testbench_simulations` command, the “`check_testbench_simulation -report_status`” command and switch reports the simulation status for the tool operations in the `<pattern_name>.simulation` sub-directory.

For a given simulation, the status normally changes as follows:

- `unscheduled` — During the compilation phase of the design, all the simulation log files under the `<pattern_name>.simulation` sub-directory are created with an empty content but with the name `<simulator>.simulation_log.unscheduled`. The tool does not queue the `<pattern_name>.simulation_script` at this point because the library of the design is not available until the compilation is completed.
- `queue` — The tool completes compilation and all simulation log files are renamed from `.unscheduled` to `<simulator>.simulation_log.queued`.
- `running` — As the simulations start running, the log file is renamed from `.queued` to `<simulator>.simulation_log.running`.

When the simulation completes, the name of the file is renamed from `.running` to `<simulator>.simulation_log`.

- `-get_status_dictionary`

An optional switch that is mutually exclusive with the `-report_status`, `-kill` and `-wait` options. When none of those options are specified, `-wait` is assumed. When you use the `-get_status_dictionary` switch, the command returns a Tcl dictionary listing the simulation status of each pattern simulated, simulating, or waiting to be simulated and found inside the `design_name_design_id.simulationpattern_id` directories located inside one of the `simulation_output_directory_list` directories. You can restrict the dictionary to a subset of

the <pattern_name>.simulation[_simulation_id] directories by using the -select or the -exclude options. The format of the returned dictionary is as follows:

```
<simulation_output_directory> {
  <pattern_name>[.<simulation_id>] {
    status  unscheduled | queued | running | pass | fail
    date    <date>
    unexpected_miscompare_count <int>
    unexpected_miscompares {
      miscompare<int> {
        object_name  <object_name>
        step_name    <step_name>
        expected_value <value>
        simulated_value <value>
      }
    }
    missing_expected_miscompare_count <int>
    missing_expected_miscompares {
      miscompare<int> {
        object_name  <object_name>
        step_name    <step_name>
        expected_value <value>
        simulated_value <value>
      }
    }
  }
}
```

- -kill

An optional switch that is mutually exclusive with the -report_status, -get_status_dictionary, and -wait options. When none of these options are specified, -wait is assumed. When you use the -kill switch, the selected running simulation will be stopped.

- -wait [-keep_simulation_data {on | off | on_failure}]

An optional switch that is mutually exclusive with the -report_status, -kill, and -get_status_dictionary options. When none of these options are specified, -wait is assumed. When you use the -wait switch, the command waits for all the simulations to be completed before returning with an error message when any of the simulations failed.

You can also use the optional -keep_simulation_data switch with the -wait option to choose how you deal with intermediate simulation files.

on — All simulation intermediate files are retained.

Note

 You can set the TESSENT_KEEP_SIMULATION_DATA environment variable to 1 to keep intermediate simulation data.

off — All simulation data is removed, irrespective of whether the simulation passes or fails.

on_failure — All passing simulation data is removed. Failing simulation data is retained. This is the default.

When running in interactive mode, the command reports a status line that is updated every second, showing how many simulations are in the unscheduled, queued, running, pass, or fail state as shown in the following.

```
check_testbench_simulations
unscheduled <int> queued <int> running <int> pass <int> fail <int>
```

The patterns that are waited on are those simulating or waiting to be simulated, and found inside the *design_name_design_id.simulation_pattern_id* directories located inside one of the *simulation_output_directory_list* directories. The list can be restricted to a subset of the *pattern_name.simulation[_simulation_id]* directories by using the `-select` or the `-exclude` options. If you ran the `run_testbench_simulations` command using the `-generate_scripts_only` option or if you issued the `check_testbench_simulation -kill` option without rerunning the `run_testbench_simulations` command, you may have simulation directories that have no simulation log file and are not scheduled to run. Those should be deleted using the `-delete` option.

Press Ctrl-C to stop the waiting and return to the interactive prompt.

- `-simulation_output_directory_list simulation_output_directory_list`
An optional switch and value pair that specifies a list of directories that contain the *design_name_design_id.simulation_pattern_id* directories. The default value is `./simulation_outdir`.
- `-simulator questa | vcs | incisive`
An optional switch and value pair to check the status of the simulator used for the simulation that was specified with the `run_testbench_simulations` command.

Examples

Example 1

The following example runs the `run_testbench_simulations` command to launch the simulations. The `check_testbench_simulation` command is then run to monitor the simulations and return an error when the simulations finish and any of them failed. If an error code is trapped by the `catch` command, the `report_status` is dumped to the transcript and the tool is terminated with an error code. If no simulation failed, the string “All sims passed” is echoed in the transcript.

```
process_patterns_specification
run_testbench_simulations
if {[catch check_testbench_simulations]} {
  check_testbench_simulations -report_status
  exit -force 1
} else {
  puts "All sims passed"
}

// sub-command: check_testbench_simulations
// Error: 2 out of 4 simulations failed:
//     MemoryBisr_BisrChainAccess with 3 unexpected mismatches
//     MemoryBist_P2.FI with 2 missing mismatches
// sub-command: check_testbench_simulations -report_status
```

```
process_patterns_specification
run_testbench_simulations
if {[catch check_testbench_simulations]} {
    check_testbench_simulations -report_status
    exit -force 1
} else {
    puts "All sims passed"
}

// sub-command: check_testbench_simulations
// Error: 2 out of 4 simulations failed:
//     MemoryBisr_BisrChainAccess with 3 unexpected mismatches
//     MemoryBist_P2.FI with 2 missing mismatches
// sub-command: check_testbench_simulations -report_status

// Simulation status for ./simulation_outdir
// =====
// -----
// Pattern Name Status      Unexpected  Missing      Date
//                               Mismatches Mismatches
// -----
// MemoryBisr_BisrChainAccess fail          3           0      Wed Oct 08 23:38:32 GMT 2014
// MemoryBist_P1           pass          0           0      Wed Oct 08 23:38:35 GMT 2014
// MemoryBist_P2           pass          0           0      Wed Oct 08 23:38:39 GMT 2014
// MemoryBist_P2 (FI)     fail          0           2      Wed Oct 08 23:38:44 GMT 2014
```

Example 2

The following example demonstrates using the -select switch:

```
> check_testbench_simulations -kill -select [list MemoryBisr_BisrChainAccess MemoryBist_P1]
```

Example 3

The following example demonstrates using the -exclude and -select switch:

```
> check_testbench_simulations -kill -exclude [list *Bisr*] -select [list MemoryBis*]
```

Example 4

The following example demonstrates how to check the status of multiple simulations based on a Tcl list:

```
# Start several simulations in several different output directories:
run_testbench_simulations -no_wait -design_name mod1a -simulation_out_dir sim_outdir_1
run_testbench_simulations -no_wait -design_name mod1b -simulation_out_dir sim_outdir_1
run_testbench_simulations -no_wait -design_name mod2 -simulation_out_dir sim_outdir_2

# Check and wait on all the simulations at the same time:
check_testbench_simulations -design_name * -design_id * -sim_out_dir_list \
    [list sim_outdir_1 sim_outdir_2]

# On completion, report all status (note how a list is used for design_name):
check_testbench_simulations -design_name [list mod1* mod2] -design_id * \
    -sim_out_dir_list [list sim_outdir_1 sim_outdir_2]
```

close_layout

Context: patterns -scan, patterns -scan_diagnosis

Mode: analysis

Closes the LDB. Any subsequent diagnosis you perform is non-layout aware.

Usage

close_layout

Description

Closes the LDB. Any subsequent diagnosis you perform is non-layout aware.

Layout-Aware Diagnosis Flow

SVDB Layout Marker Flow

Releases the Calibre Query Server and closes the layout. If you issue this command, then the tool no longer generates layout markers.

Arguments

None

Related Topics

[create_layout](#)

[open_layout](#)

close_pattern_set

Context: patterns -ijtag

Mode: analysis

Finalizes and closes the currently open pattern set.

Usage

```
close_pattern_set [-network_end_state {keep | reset | initial}]
```

Description

Must be run after the [open_pattern_set](#) command. If any iRead or iWrite commands remain that have not been processed by an iApply statement, close_pattern_set prints a warning, and then iApply processes them automatically.

By default, the end state of the IJTAG network is the one generated by the last iApply statement. When you specify the value reset or initial for the -network_end_state switch, the network is written with additional data to restore the values only in scan registers controlling the select lines of ScanMultiplexers according to switch value. When you specify the value keep for the -network_end_state switch, the result is the same as not using network_end_state, and the end state of the IJTAG network is the same as using only the close_pattern_set command.

The state of the network after running the close_pattern_set command will be the state at the beginning of the next pattern set opened by the open_pattern_set command with the -no_initial_ireset switch.

Arguments

- -network_end_state

keep — This value is the default and it specifies to not take special actions when closing the pattern set. The state of the ICL network remains in the condition reached at the end of the last iApply command.

reset — Value used when it is necessary to restore the reset state of the IJTAG network at the end of the pattern set. The reset state is restored using iWrite commands to the state control registers. State control registers control the select lines of ScanMultiplexers. The sib bits inside SIBs are an example of state control registers. These registers are written to their reset values specified in the ICL. Other scan registers are not affected. The reset state is often restored without extra scan operations, but depending on the IJTAG network configuration some network topologies may require additional scan loads.

Note

 The tool does not reset those scan registers in the scan path configuration when they are the target of an iTake command, or they receive their last written value from an explicit iWrite provided through PDL input. The tool resets scan registers in the scan path configuration that the IJTAG solver sets to fulfill an iWrite to another scan register. To determine which scan registers are not set to their reset value, use the command “[set_ijtag_retargeting_options -network_end_state_warnings on](#)” prior to closing the pattern set.

You can use this option when you need to run multiple patterns immediately after this one without doing an iReset between them. Because the reset state is restored at the end of the pattern sets, you can run them in arbitrary orders.

initial— Value used when it is necessary to restore the initial state of the IJTAG network at the end of the pattern set to what it was at the beginning of the pattern set. Restoration of the initial state is performed with iWrite commands to the state control registers. State control registers control the select lines of ScanMultiplexers. The sib bits inside SIBs are an example of state control registers. Other scan registers are not affected. The initial state is often restored without extra scan operations, but depending on the IJTAG network configuration some network topologies may require additional scan loads.

You can use this option when you need to run the same pattern set multiple times in a loop and the pattern set does not perform an iReset at the beginning. In this case, it is essential that the state of the IJTAG network is identical at the beginning of the first run as it is at the beginning of all subsequent runs. Performing a polling operation is an application in which a pattern set is run repeatedly.

You can also use this option when you need to run multiple patterns immediately after this one without doing an iReset between them and restoring a custom network state different than the state achieved by “`-network_end_state reset`”. In other words, use this option when you want to have a custom initial state at the beginning of each pattern, without doing iReset which resets the entire IJTAG network, and you want to restore the scan path to a custom state without affecting the other registers.

Note

 To specify a `network_end_state` for a `test_setup` procedure, use the “`-test_setup_network_end_state`” option of the [set_ijtag_retargeting_options](#) command.

Return Values

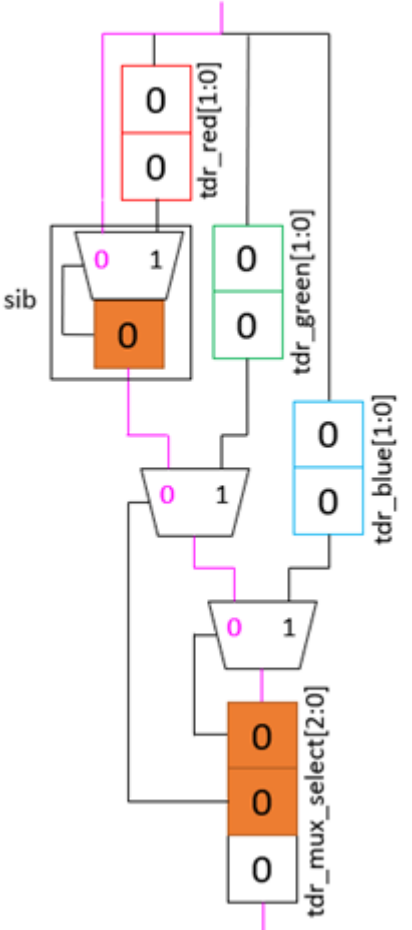

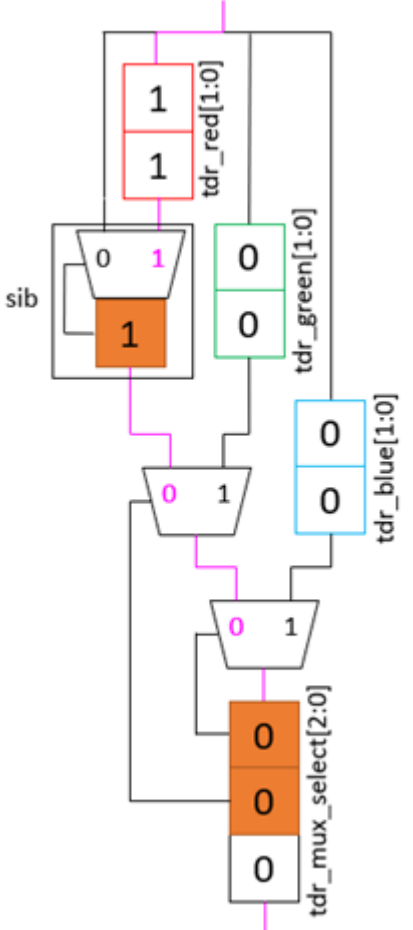

None

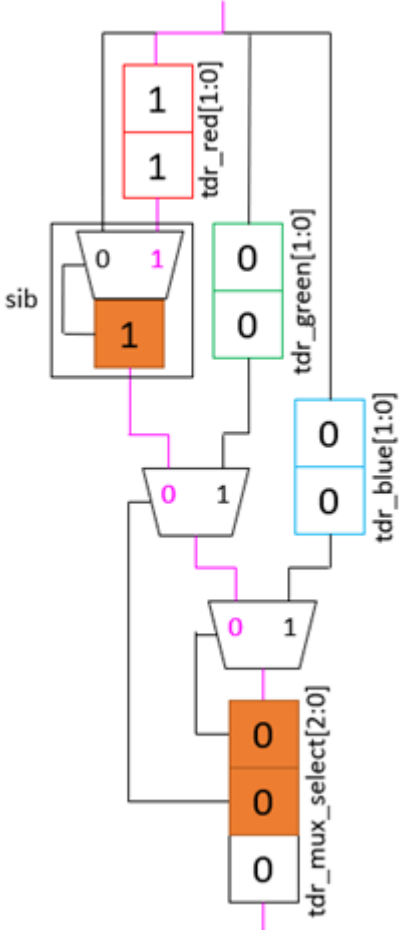

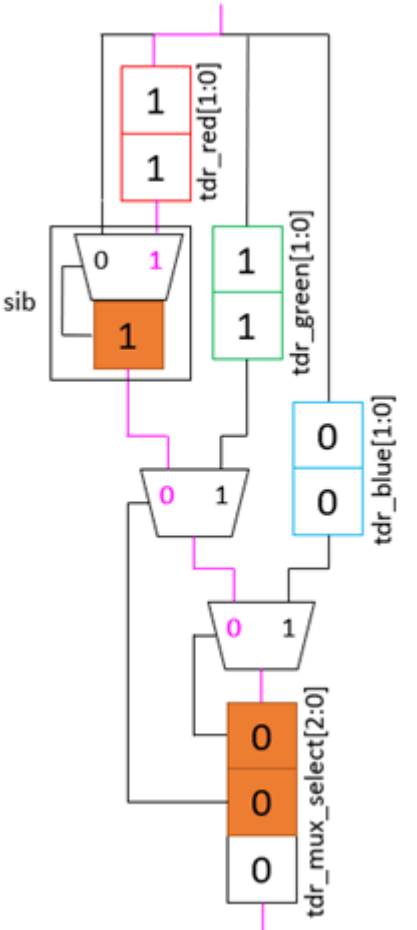

Examples

Example 1

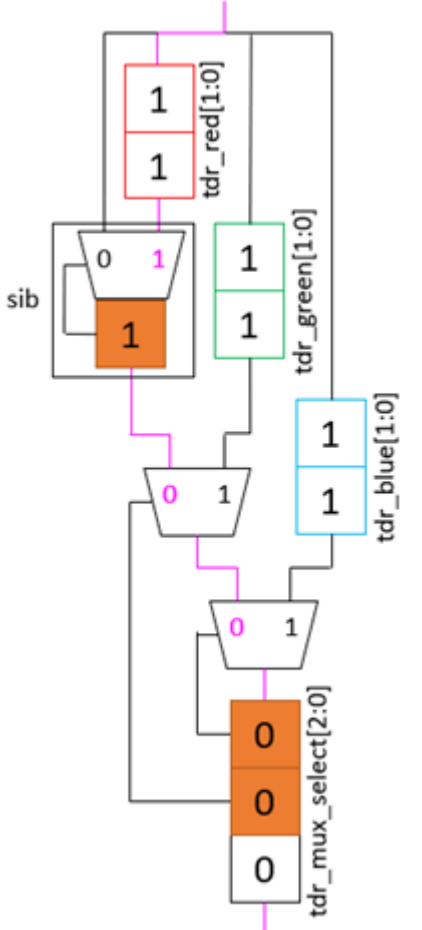

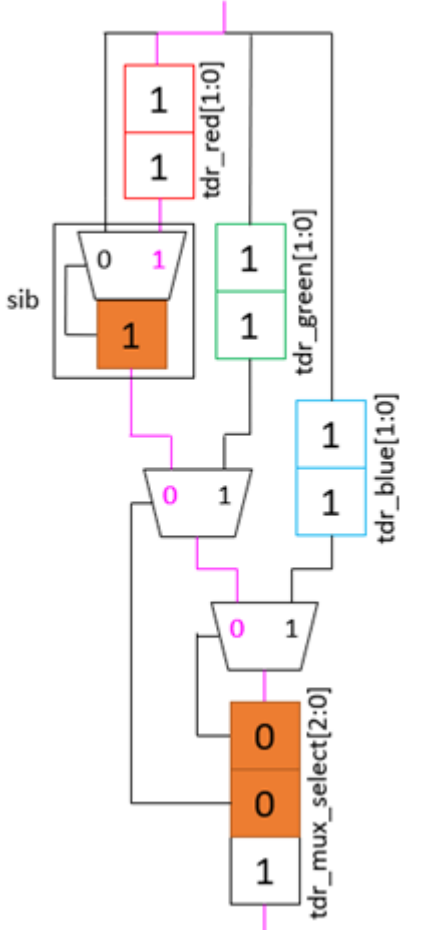

The IJTAG network consists of four TDRs, two ScanMultiplexers and one SIB. Registers filled with color control select lines of the ScanMultiplexers (including the ScanMultiplexer inside the SIB). The active scan path is marked using magenta color.

The following tables illustrate the effect of the various pattern set controls on the network state at the start of the pattern set and through the end of the pattern set.

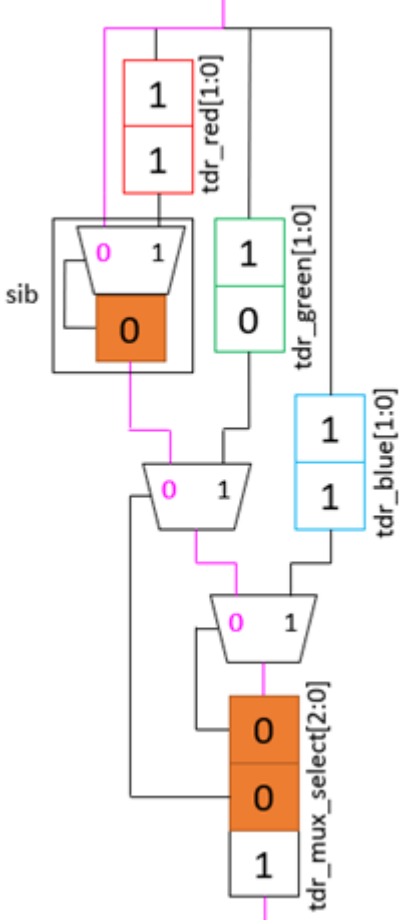

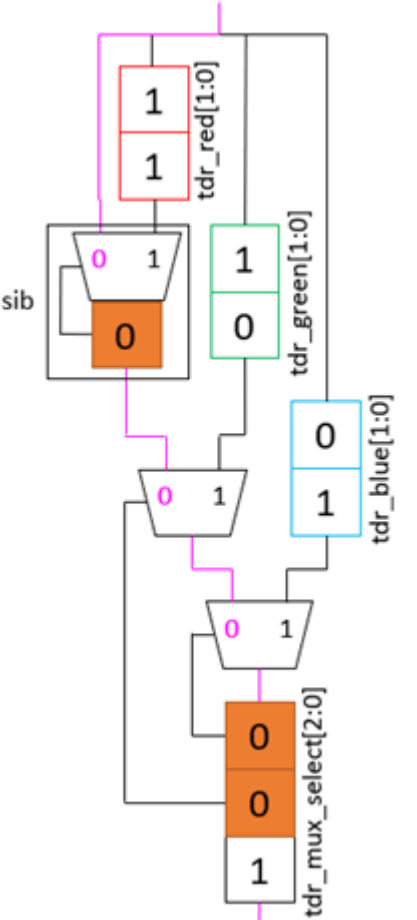

Comments and Code Examples	Network state at open_pattern_set	Network state at close_pattern_set
<p>Pattern: initial_pattern Network End State: keep</p> <p>The IJTAG network of the example is in a reset state after an iReset command. The example code writes a value of 1 to the sib bit to change the scan path to write to the tdr_red scan register. The code keeps the network end state when it closes the initial pattern.</p> <p>Tessent Shell:</p> <pre>open_pattern_set initial_pattern iWrite tdr_red.tdr 0b11 iApply close_pattern_set -network_end_state keep</pre> <p>Output PDL:</p> <pre>iProc initial_pattern {} { iWrite sib.sib 0b1 iRead sib.sib 0b0 iWrite tdr_mux_select.tdr[2:0] 0b000 iRead tdr_mux_select.tdr[2:0] 0b000 iApply iWrite tdr_red.tdr[1:0] 0b11 iRead tdr_red.tdr[1:0] 0b00 iWrite sib.sib 0b1 iRead sib.sib 0b0 iWrite tdr_mux_select.tdr[2:0] 0b000 iRead tdr_mux_select.tdr[2:0] 0b000 iApply }</pre>		

Comments and Code Examples	Network state at open_pattern_set	Network state at close_pattern_set
<p>Pattern: pattern1 Open Switch: -no_initial_ireset Network End State: initial</p> <p>Pattern1 keeps the end state of the previous pattern when it opens by using the no_initial_ireset switch. At the end of pattern1, the example code restores the scan path to the initial state found at the beginning of the pattern set. Restoring the initial network state affects only the bits driving ScanMultiplexers. The pattern may run in a loop because the beginning and the end state of the active scan path are the same.</p> <p>Tessent Shell:</p> <pre> open_pattern_set pattern1 -no_initial_ireset iWrite tdr_green.tdr 0b11 iApply close_pattern_set -network_end_state initial </pre> <p>Output PDL:</p> <pre> iProc pattern1 {} { iWrite tdr_red.tdr[1:0] 0b11 iRead tdr_red.tdr[1:0] 0b00 iWrite sib.sib 0b1 iRead sib.sib 0b0 iWrite tdr_mux_select.tdr[2:0] 0b010 iRead tdr_mux_select.tdr[2:0] 0b000 iApply iWrite tdr_green.tdr[1:0] 0b11 iRead tdr_green.tdr[1:0] 0b00 iWrite tdr_mux_select.tdr[2:0] 0b000 iRead tdr_mux_select.tdr[2:0] 0b000 iApply } </pre>	 <p>The diagram illustrates the network state at the start of the pattern set. It features a scan path with several multiplexers and registers. The tdr_red[1:0] register is set to 11, sib is 1, tdr_green[1:0] is 00, tdr_blue[1:0] is 00, and tdr_mux_select[2:0] is 010.</p>	 <p>The diagram illustrates the network state at the end of the pattern set. The tdr_red[1:0] register remains 11, sib remains 1, but tdr_green[1:0] is now 11, and tdr_mux_select[2:0] is 000.</p>

Comments and Code Examples	Network state at open_pattern_set	Network state at close_pattern_set
<p>Pattern: pattern2 Open Switch: -no_initial_ireset Network End State: initial</p> <p>Pattern2 starts and ends with the same IJTAG network state as pattern1 above. By the end of pattern2, the example code restores the scan path to the initial state found at the beginning of the pattern set</p> <p>Tessent Shell:</p> <pre> open_pattern_set pattern2 -no_initial_ireset iWrite tdr_blue.tdr 0b11 iApply close_pattern_set -network_end_state initial </pre> <p>Output PDL:</p> <pre> iProc pattern2 {} { iWrite tdr_red.tdr[1:0] 0b11 iRead tdr_red.tdr[1:0] 0b00 iWrite sib.sib 0b1 iRead sib.sib 0b0 iWrite tdr_mux_select.tdr[2:0] 0b001 iRead tdr_mux_select.tdr[2:0] 0b000 iApply iWrite tdr_blue.tdr[1:0] 0b11 iRead tdr_blue.tdr[1:0] 0b00 iWrite tdr_mux_select.tdr[2:0] 0b000 iRead tdr_mux_select.tdr[2:0] 0b000 iApply } </pre>		

Comments and Code Examples	Network state at open_pattern_set	Network state at close_pattern_set
<p>Pattern: pattern3 Open Switch: -no_initial_ireset Network End State: initial</p> <p>Pattern3 opens with explicit iWrites to tdr_mux_select to drive ScanMultiplexer select lines. By the end of pattern3, the example code restores the state of the scan path to the initial state found at the beginning of the pattern set. The code overwrites the values of the tdr_mux_select register bits 0 and 1 that control ScanMultiplexer select lines to restore the initial state.</p> <p>Tessent Shell:</p> <pre>open_pattern_set pattern3 -no_initial_ireset iWrite tdr_mux_select.tdr 0b111 iApply close_pattern_set -network_end_state initial</pre> <p>Output PDL:</p> <pre>iProc pattern3 { } { iWrite tdr_red.tdr[1:0] 0b11 iRead tdr_red.tdr[1:0] 0b00 iWrite sib.sib 0b1 iRead sib.sib 0b0 iWrite tdr_mux_select.tdr[2:0] 0b111 iRead tdr_mux_select.tdr[2:0] 0b000 iApply iWrite tdr_blue.tdr[1:0] 0b11 iRead tdr_blue.tdr[1:0] 0b00 iWrite tdr_mux_select.tdr[2:0] 0b100 iRead tdr_mux_select.tdr[2:0] 0b000 iApply }</pre>		

Comments and Code Examples	Network state at open_pattern_set	Network state at close_pattern_set
<p>Pattern: end_pattern1 Open Switch: -no_initial_ireset Network End State: reset</p> <p>By the end of end_pattern1, the example code restores the values in scan registers controlling select lines of ScanMultiplexers to values declared in the ICL ResetValue property.</p> <p>Tessent Shell:</p> <pre> open_pattern_set end_pattern1 -no_initial_ireset iWrite tdr_green.tdr 0b10 iApply close_pattern_set -network_end_state reset </pre> <p>Output PDL:</p> <pre> iProc end_pattern1 {} { iWrite tdr_red.tdr[1:0] 0b11 iRead tdr_red.tdr[1:0] 0b00 iWrite sib.sib 0b0 iRead sib.sib 0b0 iWrite tdr_mux_select.tdr[2:0] 0b110 iRead tdr_mux_select.tdr[2:0] 0b000 iApply iWrite tdr_green.tdr[1:0] 0b10 iRead tdr_green.tdr[1:0] 0b00 iWrite tdr_mux_select.tdr[2:0] 0b100 iRead tdr_mux_select.tdr[2:0] 0b000 iApply } </pre>		

Comments and Code Examples	Network state at open_pattern_set	Network state at close_pattern_set
<p>Pattern: end_pattern2 Open Switch: -no_initial_ireset Network End State: reset</p> <p>By the end of end_pattern2, the example code restores the values in scan registers controlling select lines of ScanMultiplexers to values declared in the ICL ResetValue property.</p> <p>Tessent Shell: <pre>open_pattern_set end_pattern2 -no_initial_ireset iWrite tdr_blue.tdr 0b01 iApply close_pattern_set -network_end_state reset</pre></p> <p>Output PDL: <pre>iProc end_pattern2 {} { iWrite sib.sib 0b0 iRead sib.sib 0b0 iWrite tdr_mux_select.tdr[2:0] 0b101 iRead tdr_mux_select.tdr[2:0] 0b000 iApply iWrite tdr_blue.tdr[1:0] 0b01 iRead tdr_blue.tdr[1:0] 0b00 iWrite tdr_mux_select.tdr[2:0] 0b100 iRead tdr_mux_select.tdr[2:0] 0b000 iApply }</pre></p>	 <p>The diagram illustrates the network state at the 'open_pattern_set' phase. It features several components: a sib register (orange) with value 0; tdr_red[1:0] (red) with values 1 and 1; tdr_green[1:0] (green) with values 1 and 0; tdr_blue[1:0] (blue) with values 1 and 1; and tdr_mux_select[2:0] (orange) with values 0, 0, and 1. Multiplexers are shown with select lines 0 and 1. The circuit is connected to a network of lines.</p>	 <p>The diagram illustrates the network state at the 'close_pattern_set' phase. It features several components: a sib register (orange) with value 0; tdr_red[1:0] (red) with values 1 and 1; tdr_green[1:0] (green) with values 1 and 0; tdr_blue[1:0] (blue) with values 0 and 1; and tdr_mux_select[2:0] (orange) with values 0, 0, and 1. Multiplexers are shown with select lines 0 and 1. The circuit is connected to a network of lines.</p>

Note

 Patterns from Example1 which begin and end with the same active scan path may be run in a loop.

```
open_pattern_set sequence1
  iCall initial_pattern
  //any sequence of pattern1, pattern2 or pattern3
  iCall pattern1
  iCall pattern2
  iCall pattern2
  iCall pattern3
  //end_pattern1 starts from initial state
  iCall end_pattern1
  //end_pattern2 starts from reset state
  iCall end_pattern2
  //end_pattern3 starts from reset state
  iCall end_pattern3
close_pattern_set
```

```
open_pattern_set sequence2
  //end_pattern2 starts from reset state
  iCall end_pattern2
  iCall end_pattern2
  //initial_pattern starts from reset state
  iCall initial_pattern
  iCall pattern3
  iCall pattern2
  iCall pattern1
  //end_pattern1 starts from initial state
  iCall end_pattern1
  //end_pattern3 starts from reset state
  iCall end_pattern3
close_pattern_set
```

```
open_pattern_set sequence3
  iCall initial_pattern
  //any sequence of pattern1, pattern2 or pattern3
  iCall pattern1
  iCall pattern1
  iCall pattern3
  //end_pattern1 starts from initial state
  iCall end_pattern1
  //initial_pattern starts from reset state
  iCall initial_pattern
  iCall pattern2
  iCall pattern2
  //end_pattern1 starts from initial state
  iCall end_pattern1
  //end_pattern2 starts from reset state
  iCall end_pattern2
  iCall end_pattern2
  iCall end_pattern2
  iCall end_pattern3
close_pattern_set

close_tsdb

Context: all contexts

Mode: all modes

Makes the contents of a previously opened TSDB directory invisible to the tool.

Usage

```
close_tsdb {directory_path_list | -all} [-silent]
```

Description

The specified TSDB output directory is automatically opened and cannot be closed with this command.

Arguments

- ***directory_path_list***
A required string that specifies an absolute or relative path to a TSDB directory, or a Tcl list containing one or many absolute or relative paths to TSDB directories. You must specify either the ***directory_path_list*** or **-all** option, but you cannot specify both.
- **-all**
A required option that specifies that all previously opened TSDB directories are to be closed. Note that the specified TSDB output directory is automatically opened and remains opened. You must specify either the ***directory_path_list*** or **-all** option, but you cannot specify both.
- **-silent**
An optional switch that suppresses the warning that is normally generated if the specified ***directory_path_list*** is not currently opened or if there are no opened TSDB directories when the **-all** option is used.

Examples

This example closes two TSDB directories with one command invocation.

```
get_tsdb_list
```

```
/home/projects/chipa/tsdbs/corea.tsdb  
/home/projects/chipa/tsdbs/corec.tsdb
```

```
close_tsdb [list ${tsdb_home}/corea.tsdb ${tsdb_home}/coreb.tsdb ]  
get_tsdb_list
```

```
/home/projects/chipa/tsdbs/corec.tsdb
```

close_visualizer

Context: unspecified, all contexts

Mode: all modes

Saves display data and closes Tessent Visualizer.

Usage

`close_visualizer [-server]`

Description

Saves display data and closes the Tessent Visualizer client application. Selecting “X” from the window control buttons  performs the same function as `close_visualizer`.

Note

 The appearance of the window control buttons may differ from the above, depending on the particular desktop environment used.

Display data is automatically saved and remains persistent for the current tool session unless the `-server` option is used.

Arguments

- `-server`
An optional switch that closes a Tessent Visualizer server. When the server is closed, all Visualizer-specific data such as schematic contents, opened Text/HDL Viewer and diagnosis report files, and filters are reset.

Examples

The following example opens Tessent Visualizer, displays the Flat Schematic window, and creates and displays a portion of the design, then closes the viewing session:

```
open_visualizer -display flat_schematic  
add_schematic_objects /alu_inst/lui/z_reg[1]  
close_visualizer
```

The following example opens and then closes a Tessent Visualizer server:

```
open_visualizer -server_only  
close_visualizer -server
```

collect_cdp_test_failure_logs

Context: patterns -silicon_insight

Mode: all modes

Saves failure logs for a CDP test to a directory.

Usage

collect_cdp_test_failure_logs *test_name_list* [-flog_directory *flog_directory*] [-force]

Description

The collect_cdp_test_failure_logs command runs the main pattern and all diagnostic ATPG patterns for the specified test or tests and saves the failure logs in the specified directory.

Arguments

- *test_name_list*
A required string or Tcl list that identifies one or more CDP tests to collect failure logs from.
- -flog_directory *flog_directory*
An optional switch and string that specifies the directory in which to create directories that contain the failure files for each specified CDP test. The default directory is the current working directory.
- -force
An optional switch that collects failure logs even if the main pattern passes.

compare_collections

Context: unspecified, all contexts

Mode: all modes

Compares the contents of two collections.

Usage

compare_collections *collection1 collection2* [-order_dependent]

Description

If the same objects are in both collections, the result is 0 (zero). If the objects in the collections are different, the result is a non-zero value. The order of the objects can optionally be considered by using the -order_dependent switch.

If two empty collections are compared, the compare_collections command considers them identical and returns a result of 0 (zero).

Arguments

- *collection1*
A required string that specifies the base collection for the comparison.
- *collection2*
A required string that specifies the collection to compare with *collection1*.
- -order_dependent
An optional switch that causes the order of the objects to be considered when comparing the collections. The collections are considered to be different if the objects are ordered differently, and a non-zero value is returned.

Examples

The following example shows a variety of comparisons.

```
set a [get_ports a*]
{a[3] a[2] a[1] a[0]}

set b [get_ports b*]
{b[3] b[2] b[1] b[0]}

set c [get_ports c*]
{}

#Same objects, same order
compare_collections $a $a

0
```

#Same objects, same order
compare_collections \$a \$a -order_dependent

0

#Different objects
compare_collections \$a \$b

1

#Different objects
compare_collections \$a \$b -order_dependent

1

#Two null collections
compare_collections \$c \$c

0

#Same objects, different order
compare_collections [add_to_collection \$a \$b] [add_to_collection \$b \$a]

0

#Same objects, different order
compare_collections [add_to_collection \$a \$b] [add_to_collection \$b \$a] -order_dependent

compress_layout

Context: patterns -scan_diagnosis

Mode: analysis

Compresses a LDB.

Usage

LDBs created after v2013.3: `compress_layout`

LDBs created with v2013.3 and before: `compress_layout layout_database_name`

Description

You must open the LDB using the [open_layout](#) command before performing the compression operation.

Refer to “[Layout Database Compression and Decompression](#)” in the *Tessent Diagnosis User's Manual* for complete information.

Arguments

- *layout_database_name*

A required string that specifies the location to and the name of the LDB to be created during the compression operation.

Related Topics

[create_layout](#)

[open_layout](#)

[uncompress_layout](#)

compress_patterns

Context: dft -edt, patterns -scan

Mode: analysis

Compresses patterns in the current test pattern set.

Usage

```
compress_patterns [passes_integer] [-Reset_au] [-MAx_useless_passes integer]  
  [-MIn_elim_per_pass integer] [-MULTiple_detection [-Order]]  
  [-MIXed {Essential | Order [-Delta percentage] [-Limit integer]}]
```

Description

Note

 You should use create_patterns for the smallest pattern set. The compress_patterns command is for specialized processes.

The compress_patterns command performs static pattern compression on the current test pattern set by repeating fault simulation for the patterns in either reverse or random order and selecting only those patterns required for detection. The *passes_integer* argument specifies the number of pattern compression passes. The first pattern compression pass runs in reverse order and then alternates between random and reverse for additional passes. If you do not specify a *passes_integer* argument, the tool performs only one compression pass.

This is a multiprocessing command for fault simulation. This command supports IDDQ fault models. For more information about multiprocessing, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User’s Manual*.

If you specify the -Reset_au option, then when the tool performs pattern compression, it selects the AU faults for later fault simulation. If during pattern compression these AU faults simulate as possible-detected, the tool labels them as PU (possible-detected—ATPG_untestable), and they receive test coverage credit as possible-detected faults. If the number of pattern compression passes is greater than 1, the tool only performs the resetting of the AU faults for the first pass.

The compress_patterns command has a residual memory effect. The initial mode (reverse/random) is not fixed. Instead, it toggles back and forth, starting with the mode last used in the same run. The tool always starts with the reverse order at invocation.

If you include the -Multiple_detection switch, the static compression performed by this command does not simulate faults in the posdet (PD) fault class (PT and PU subclasses) and as a result, the tool may discard patterns that detect PD faults. Therefore, the test coverage reported after using this command switch may not be accurate if there are PD faults. To ensure you get

the most accurate report of test coverage in this case, re-simulate the patterns using one of the following approaches:

- Enter the “[set_system_mode](#) analysis” command followed by the [simulate_patterns](#) command.
- Enter the [order_patterns](#) command with the -Simulate option.

Arguments

- *passes_integer*
An optional integer that specifies the number of pattern compression passes. The default is 1 (performs only one compression pass).
- -Reset_au
An optional switch that specifies fault simulation of AU faults.
- -MAx_useless_passes *integer*
An optional switch and integer pair that specifies the maximum number of consecutive, useless (no eliminated patterns) passes the tool permits before terminating the pattern compression process. This command option has no effect on the pattern set if the number of passes (*passes_integer* argument) is smaller than the *integer* value of this switch. The default is the *passes_integer* value.
- -MIn_elim_per_pass *integer*
An optional switch and integer pair that specifies the minimum number of eliminated patterns required in a single pass to continue the pattern compression process. If you specify this switch, you must enter a value greater than 0.
- -Multiple_detection
An optional switch that specifies for the tool to use a multiple detection based algorithm to carry out static pattern compaction. When you use this switch, the tool runs only one pass of compaction and discards patterns that detect only posdet (PD) faults.
- -Order
An optional switch used with the -Multiple_detection switch to specify pattern ordering at the same time as static pattern compaction.
- -MIXed Essential | Order
An optional switch and string pair that specifies to use a mixed compaction technique to compact the current internal pattern set. If you use the “Essential” option, the tool considers essential faults, those faults detected only once in the pattern set, as candidates for dynamic compaction. This option ensures that the patterns used to detect the essential faults are not dropped during pattern compression to keep the reached coverage.

If you use the “Order” option, the tool selects fault candidates for dynamic compaction based on pattern set ordering.

Note

-  Using the “-Mixed Order” switch turns off pattern classification until you issue a “set_pattern_classification On” command.

Mixed compaction can reduce the size of the current internal pattern set in most situations, but Siemens EDA cannot guarantee that in every case the size of the pattern set after the tool performs mixed compaction is less than the size of the pattern set before mixed compaction. Therefore, be sure to save the current internal pattern set before carrying out mixed compaction.

- **-Limit *integer***

An optional switch and integer pair that modifies the behavior of the -Mixed option. The -Limit switch specifies the maximum number of faults that the tool attempts unsuccessfully to merge with the target fault pattern when dynamic compaction is involved. Without the -Limit switch, -Mixed causes the tool to use an adaptive algorithm to determine this number.

- **-Delta *percentage***

An optional switch and real number pair (between 0 and 100) that modifies the behavior of the -Mixed Order option. Normally, -Mixed Order selects fault candidates for dynamic compaction based on pattern set ordering. The -Delta switch causes the tool to consider as candidates for dynamic compaction, the specified percentage of the total number of faults instead of using pattern set ordering. The default percentage is 2.

Examples

The following example compresses the generated test pattern set with two passes; the first pass is by reverse order and the second pass is by random order:

```
set_system_mode analysis
create_patterns
compress_patterns 2
```

convert_design_path_format

Context: all contexts

Mode: all modes

Converts a list of design paths to the specified dot or slash separator.

Usage

```
convert_design_path_format design_path_list {-to_dot_separator | -to_slash_separator}
```

Description

The `convert_design_path_format` command accepts a list of design instance names and performs a conversion of the hierarchy separators according to the selected option. The command returns the converted names in a list of the same size as specified with the command.

Arguments

- *design_path_list*
A required list that specifies the design instance hierarchical paths to be converted. In cases where the *design_path_list* contains escaped identifiers, ensure correct formatting of the input list is maintained. The Tcl “list of lists” construct can be used to avoid breaking the hierarchical name into parts at the white spaces terminating the escaped identifiers.
- `-to_dot_separator`
A switch that specifies the hierarchical paths are converted to “.” separators in the path name. This option is mutually exclusive with the `-to_slash_separator` option.
- `-to_slash_separator`
A switch that specifies the hierarchical paths are converted to “/” separators in the path name. This option is mutually exclusive with the `-to_dot_separator` option.

Examples

The following example demonstrates the conversion of two hierarchical design instance paths from slash separators to dot separators:

```
SETUP>convert_design_path_format {core/modA/blockB core/modB/blockB} \  
-to_dot_separator  
core.modA.blockB core.modB.blockB  
SETUP>
```

copy_collection

Context: unspecified, all contexts

Mode: all modes

Duplicates the contents of an existing collection, resulting in a new collection. The base collection remains unchanged.

Usage

`copy_collection` *collection*

Description

The only time you need to copy a collection is when you want to append to one copy while leaving the original copy unchanged. Copying a collection is equivalent to using [add_to_collection](#) with an empty collection as the second collection.

Arguments

- *collection*

A required string that specifies the collection to be copied.

Examples

The following example shows the results of copying a collection and then appending to the copy. Note how *a2* is modified by [append_to_collection](#), but *a1* remains unaffected. The second reference to *a2* called *a3* sees the updated collection because it is simply a second reference to the same collection referenced by *a2*.

```
set a1 [get_ports a*]
{a[3] a[2] a[1] a[0]}

set a2 [copy_collection $a1]
{a[3] a[2] a[1] a[0]}

set a3 $a2

append_to_collection a2 [get_ports b[0]]
{a[3] a[2] a[1] a[0] b[0]}

puts [get_name_list $a1]
{a[3]} {a[2]} {a[1]} {a[0]}

puts [get_name_list $a2]
{a[3]} {a[2]} {a[1]} {a[0]} {b[0]}

puts [get_name_list $a3]
{a[3]} {a[2]} {a[1]} {a[0]}
```

copy_module

Context: all contexts

Mode: insertion

Creates an exact copy of a design module and assigns it a new name so that it can then be used as part of a `create_instance` and `replace_instances`.

Usage

```
copy_module obj_spec -new_name module_name [-silent]
```

Description

Creates an exact copy of a design module and assigns it a new name so that it can then be used as part of a `create_instance` and `replace_instances`.

The `copy_module` command returns a collection with one module object corresponding to the newly created module.

Arguments

- ***obj_spec***
A required value that specifies a module name or a collection containing a single module object as returned by the `get_modules` command.
- **-new_name *module_name***
A required switch and value pair that specify the name of the new module once it has been copied. If *module_name* already exists, the module is copied and “_integer” is appended to the end of the *module_name* where integer increments as each new module of the same name is added.
- **-silent**
An optional switch that suppresses the error that is normally generated if *obj_spec* does not point to a single module that exists. A null collection is returned when an error was suppressed. This option also suppresses the error that is generated if the specified *module_name* already exists.

Examples

Example 1

The following example creates a copy of module ModA to ModB. ModB is identical to ModA and can be instantiated into the design.

```
copy_module ModA -new_name ModB  
{ModB}
```

Example 2

The following example introspects the module name of an instance to create a copy.

copy_module

copy_module [get_att_value u1/u2 -name module_name] -new_name ModB

{ModB}

copy_simulation_context

Context: all contexts

Mode: setup, analysis

Prerequisite: A flat model must currently exist.

Copies the simulation values and forces from one simulation context to another.

Usage

```
copy_simulation_context [-from source_context_name] [-to target_context_name]
```

Description

The `copy_simulation_context` command copies the simulation values and forces from any predefined or user-defined simulation context to any user-defined simulation context.

Note that you must specify either the `-to` or the `-from` switch, or specify both switches.

Arguments

- `-from source_context_name`

An optional switch and string pair that specifies the simulation context from which to copy the simulation values and forces. The `source_context_name` can be predefined (listed in [Table 6-8](#) on page 2291) or user-defined. If you do not use this switch and you do supply the `-to` switch, the command uses the current simulation context as the `source_context`.

- `-to target_context_name`

An optional switch and string pair that specifies the simulation context to which to copy the simulation values and forces. The `target_context_name` can be any user-defined context name that already exists and cannot be a predefined context name (listed in [Table 6-8](#) on page 2291). If you do not use this switch and you do use the `-from` switch, the command uses the current simulation context as the `target_context`.

Examples

The following examples show two ways to copy the simulation values of the predefined simulation context, `stable_load_unload`, to the user-defined simulation context, `myContext`:

```
SETUP> set_current_simulation_context myContext
SETUP> copy_simulation_context -from stable_load_unload
```

You can accomplish the same as the above with a single command:

```
SETUP> copy_simulation_context -from stable_load_unload -to myContext
```

create_bisr_segment_order_file

Context: all contexts

Mode: analysis

Creates the BisrSegmentOrderSpecification configuration data wrapper and extracts the list and ordering of BISR chain segments.

Usage

```
create_bisr_segment_order_file [design_id] [-replace]
```

Description

This command extracts the list of repairable memory instances by inspecting the ICL file and performing design introspection of all memories that have the [set_memory_instance_options](#) -use_in_memory_bisr_dft_specification attribute set. The ScanInPort pins of BISR chains found on child instances within included ICL modules are also extracted.

When a DEF/PDEF file is available, the BISR chain is extracted and the ordering is optimized based on the coordinates of the memory instances. If the DEF/PDEF is specified for a block instance, the ordering is optimized based on the block's BISR_SI pin coordinates. If a block's BISR_SI pin does not have the coordinates specified, but the parent block does, those coordinates are used for ordering optimization. If DEF/PDEF information is not available, the BISR chain is alphabetically sorted by memory instance names.

The BISR Segment Order File can be edited and the BISR chain can be re-ordered during the insertion phase of the design flow. Any BISR registers that do not appear in the BISR Segment Order File does not have a BISR module generated and has its repair ports untouched. For further information on assigning and controlling BISR chains, refer to the “[Inserting BISR Chains in a Block](#)” topic in the *Tessent MemoryBIST User's Manual For Use With Tessent Shell* manual.

The format of the BISR Segment Order File containing the BisrSegmentOrderSpecification wrapper is shown in [Figure 10-60](#). The file containing the BisrSegmentOrderSpecification wrapper is referenced by the DftSpecification/[MemoryBisr](#) bisr_segment_order_file : *filename* property.

Arguments

- *design_id*
An optional string that identifies the design. The default is the current design.
- -replace
An optional switch that specifies the existing wrapper is to be replaced. If the command is run and finds a BISR Segment Order File already exists for the specified *design_id*, an error is generated informing the user to use -replace.

create_capture_procedures

Context: dft -edt, patterns -scan

Mode: analysis

Creates named capture procedures based on clock sequences either derived from patterns or specified at the command line.

Usage

```
create_capture_procedures [-Name capture_procedure_name]  
  {-PAtterns [Internal | External] [pattern_index...] |  
  {{-Clock_sequence clock_sequence | -SAME_clocks_pulse  
  {Single_clock_per_procedure | GRoup_noninteracting_clocks_per_procedure}  
  [pulse_times]} [-FORce_pi [cycle_number...]] [-MAsk_po]  
  [-SLOW_cycles {cycle_number...}] [-Load_cycles {cycle_number...}]  
  [[-COndition pinpathname value [cycle_number...]]...]  
  [[-TImeplate [Fast | Slow] timeplate_name]...]  
  [{-EXT_Clock_sequence clock_sequence | -EXT_Same_clock_pulse external_clock_name  
  pulse_times} {-EXT_Timeplate timeplate_name]]} [{>|>>} file_pathname]
```

Description

Use the `create_capture_procedures` command before or after pattern generation. This command creates the procedures in the internal memory only. Save the procedure to a test procedure file using the `write_procfile` command.

For information on using named capture procedures, see “[At-Speed Test With Named Capture Procedures](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- -Name *capture_procedure_name*

An optional switch and string pair that specifies the name of the capture procedure to create. If there is already a procedure with this name, a suffix is added to the name specified. If this command creates multiple named capture procedures, it uses the specified *capture_procedure_name* as the prefix of each name and adds a suffix. If you do not specify -Name, the default name is “user_capture_proc<n>,” where <n> is an integer suffix.

- -PAtterns [Internal | External] [*pattern_index...*]

A switch that specifies which patterns to extract clock sequences from for the named capture procedures. The following options are available:

[Internal | External] — An optional literal that extracts clock sequences from internal or external patterns. The default is internal if not specified.

[*pattern_index...*] — An optional, repeatable string that extracts clock sequences from the patterns with the specified index. The pattern index starts at 1. By default, the tool extracts clock sequences from all the patterns of the internal or external pattern set if a pattern index is not specified.

- **-Clock_sequence** *clock_sequence*

A switch and string pair that specifies the clock sequence for the named capture procedure. *clock_sequence* is a sequence of cycles. A cycle is denoted by one or more clocks enclosed by a pair of parentheses. Adjacent clocks within a cycle must be separated by either white space or a comma. The clock is designated by the gate identification number or pin pathname. For example, (c1,c2) (c1) (c2,c3) represents a clock sequence with three cycles. In the first cycle, clock c1 and c2 are pulsed; in the second cycle, clock c1 is pulsed; in the third cycle, clock c2 and c3 are pulsed.

- **-SAME_clocks_pulse** {**Single_clock_per_procedure** | **GRoup_noninteracting_clocks_per_procedure**} [*pulse_times*]

A switch, literal, and optional value that automatically generate intra clock domain named capture procedures.

Single_clock_per_procedure — A literal that pulses a single clock in every pulse cycle. The command creates a named capture procedure automatically for every clock in the design that is not constrained to its off state value. Also, all clocks defined as its equivalence are pulsed when a single clock is pulsed in every cycle.

GRoup_noninteracting_clocks_per_procedure — A literal pulses a clock group, which consists of a group of non-interacting clocks, in every pulse cycle. Each clock group consists of a maximal set of non-interacting clocks. Once clocks are classified into groups, a named capture procedure is created for every clock group. (To understand the difference between non-interacting and interacting clocks, see the description of interacting clocks in the “domain_clock” and “-any_interaction” options in the [set_clock_restriction](#) command.)

pulse_times — An optional value that specifies the number of cycles that pulse clock(s). By default, *pulse_times* is 2 if not specified.

- **-FORce_pi** [*cycle_number...*]

An optional switch and repeatable integer that force PI values in the specified cycle(s). If *cycle_number* is not specified, all the cycles contain the force_pi statement. By default, only the first cycle contains the force_pi statement. The cycle number starts at 1.

- **-MAsk_po**

An optional switch that specifies the last cycle contains no measure_po statement. By default, the last cycle contains measure_po to indicate the time when the PO measurement happens.

- **-Slow_cycles** {*cycle_number...*}

An optional switch and repeatable integer that specify the slow cycles of the procedure.

- **-Load_cycles** {*cycle_number...*}

An optional switch and repeatable integer that specify where the scan load happens before the capture cycles of the procedure. By default, only the single scan load happens before the first cycle.

- **-C**Ondition *pinpathname value [cycle_number]*
An optional switch, pin pathname, integer, and cycle integer that specify a condition of the scan cells in the named capture procedure. If you do not specify *cycle_number*, the condition is a global condition; otherwise, the condition is a local condition associated with the specified cycle only.
- **-T**imeplate [**F**ast | **S**low] *timeplate_name*
An optional switch, literal, and string that specify the timeplate for the fast or slow cycles of the named capture procedure. By default, the specified timeplate applies to the fast cycles of the named capture procedure.

If you do not specify this optional switch, the named capture procedures use the default timeplate. You can define the default timeplate by specifying the Set Default_timeplate statement in the procedure file.
- **-EXT_Clock_sequence** *clock_sequence* | **-EXT_Same_clock_pulse** *external_clock pulse_times* [**-EXT_Timeplate** *timeplate_name*]
An optional switch, string, and value that automatically create the external mode of the named capture procedures. Do not use this switch together with the **-Patterns** switch.
 - EXT_Clock_sequence** *clock_sequence* — An optional switch and string pair that specifies the clock sequence for the external mode of the named capture procedure. *clock_sequence* is a sequence of cycles. A cycle is denoted by one or multiple clocks enclosed by a pair of parentheses. Adjacent clocks within a cycle must be separated by either white space or a comma. The designated clock or clocks must be an external clock or clocks.
 - EXT_Same_clock_pulse** *external_clock pulse_times* — An optional switch, string, and value that specify to pulse an external clock in every cycle in the external mode. You can specify the external clock by its gate identification or pin pathname. *pulse_times* specifies the number of cycles that pulse the external clock.
 - EXT_Timeplate** *timeplate_name* — An optional switch and string that specifies the timeplate to use for the external mode of the named capture procedure. The default timeplate is used if this optional switch is not specified.
- **>** *file_pathname*
An optional redirection operator and pathname pair used at the end of the argument list to create or replace the contents of *file_pathname*.
- **>>** *file_pathname*
An optional redirection operator and pathname pair used at the end of the argument list to append the contents of *file_pathname*.

Examples

Example 1

The following example creates named capture procedures based on the clock sequences extracted from internal patterns.

```
set_system_mode analysis
create_patterns
create_capture_procedures -name my -patterns internal
```

Example 2

The following example creates named capture procedures based on the clock sequences extracted from the 1st, 12th, and 20th patterns in the external pattern set.

```
read_patterns pattern_file
create_capture_procedures -name my -patterns external 1 12 20
```

Example 3

The following example creates a named capture procedure of two cycles for every non-constrained clock in the design.

```
create_capture_procedures -same_clocks_pulse single_clock_per_procedure 2
```

Example 4

The following example creates a named capture procedure with a user-defined clock sequence. The defined clock sequence has four clock cycles. In cycle 1, clock1 is pulsed. In cycle 2, clock1 and clock2 are pulsed simultaneously. In cycle 3, clock1 and clock3 are pulsed simultaneously. In cycle 4, clock1 is pulsed and PO is measured. In this example, all cycles are at-speed cycles.

```
create_capture_procedures -clock_sequence (clock1) (clock1, clock2) (clock1, clock3) \
(clock1)
```

Example 5

The following example creates a named capture procedure using the same clock sequence defined in the previous example. In the first cycle, the scan cell needs to satisfy the condition of having the loading value of 1.

```
create_capture_procedures -clock_sequence (clock1) (clock1, clock2) (clock1, clock3) \
(clock1) -condition /inst_core/inst_iacc/inst_reg 1 1
```

create_connections

Context: all contexts

Mode: insertion

Connects pin, net, or port objects.

Usage

Usage 1: N-to-N pairing connections

```
create_connections object_spec1 object_spec2  
[-net_name net_name] [-net_uniquification_suffix net_uniquification_suffix] [-silent]
```

Usage 2: 1-to-N broadcast connections

```
create_connections object_spec1 object_spec2  
[-net_name net_name] [-net_uniquification_suffix net_uniquification_suffix]  
[-treat_common_ancestor_as_unique on | off] [-silent]
```

Usage 3: N-to-1 constant connections

```
create_connections object_spec1 -constant {1 | 0}  
[-net_name net_name] [-net_uniquification_suffix net_uniquification_suffix] [-silent]
```

Description

You can connect any of the object types pins, nets, or ports as described here:

Usage 1: When *object_spec1* and *object_spec2* contain the same number of elements, the tool pairs the elements from the two lists in the order of the two lists and creates a connection between each pair. Only one driver element per pair is permitted.

Usage 2: When *object_spec1* has one element, and *object_spec2* has one or more elements, *object_spec2* cannot include any driver elements, such as an input port or an output pin.

Usage 3: When you specify *-constant*, you cannot specify *object_spec2* and *object_spec1* cannot contain any driver element, such as an input port or an output pin.

When the *-net_name* option is not specified, the net and pin name used to create the connection is automatically inferred from the name of the elements within *object_spec1* using the following algorithm:

- If the element in *object_spec1* is a pin, the tool uses the *leaf_pin_name* unless it has fewer than three characters; if it has fewer than three characters, the tool uses the *leaf_instance_name* of the pin concatenated with the *leaf_name* of the pin and separated by an underscore.
- If the element in *object_spec1* is a net or a port, the tool uses the leaf name irrespective of the number of character it has.

You can override the default net name by using the `-net_name` switch and specifying the `net_name` option to be used to create the intermediate nets and pins. Regardless of whether the default or a user-specified net name is specified, the tool checks for net conflicts and uniquifies the newly created net to avoid accidental shorts. The uniquify operation is performed using the `net_uniquification_string` suffix specified with the `set_insertion_options` command.

The two endpoints of each connection may be in different parts of the design hierarchy. The tool creates all of the intermediate pins needed to create the connection through the hierarchy. The tool automatically reuses existing pins that already make up part of the requested connection.

If you connect more than one pin within a given instance to a common source outside the instance, the tool creates only a single pin on the instance interface and reuses that same pin for all of the connections you want to be specified within the instance.

Arguments

- ***object_spec1 object_spec2***

A required value that specify a set of endpoints of the connections to be created. The value of the `object_spec` argument can be a Tcl list of one or more pin, port, or net names; or a collection of one or more pin, port, or net objects.

The size of `object_spec1` must either be one or equal to the size of the `object_spec2` when `object_spec2` is specified. The `object_spec1` argument cannot include any driver elements when you specify the `-constant` option. At most, one driver can exist in each connection pair when you specify both `object_spec1` and `object_spec2`.

If an object does not exist within one of the `object_spec` and you specify the `-silent` option, the tool ignores the object and skips the connection request. If the object does not exist and you do not specify the `-silent` option, the tool generates an error.

- **`-constant 1 | 0`**

A switch and literal pair that specifies a constant value to connect to all elements within `object_spec1`. The `-constant` switch is mutually exclusive with the `object_spec2` argument.

When this option is specified, the `object_spec1` argument cannot contain any driver elements such as input ports or output pins. In Verilog, a `1'b0` or `1'b1` connection is used as the connection to the pins, and a `buf` primitive or an `assign` statement with its input connected to `1'b0` or `1'b1` is used as the connection to output ports or to nets.

- **`-net_name net_name`**

An optional argument that specifies the name of the pin created on `object_spec1` or `object_spec2` to route the connection. If `-net_name` is not specified, the tool uses the leaf name of `object_spec1` to name the pin. If `object_spec1` is a pin and its leaf name has fewer than three characters, the tool uses the leaf instance name of the base name of the pin concatenated with the leaf pin name and separated by an underscore.

- `-net_uniquification_suffix` *net_uniquification_suffix*

An optional argument that defines the string that Tessent Shell uses to uniquely a net when the net that is trying to be created already exists in the design. The string must contain letters, numbers, or underscores and one and only one # symbol at the end identifying a counter that is auto-incremented starting from 1 until the net name does not already exist. For example, specifying `-net_uniquification_suffix` of `_TS#` appends the string `_TS#` to the net where # is replaced by the first integer above 0, making the net name unique. If net A, B, and B_TS1 already exist in the design, Tessent Shell would use A_TS1 if it needed to create a new net with default name A and would use B_TS2 if it tried to create a new net with default name B.

When unspecified, the suffix defaults to the value set by the `set_insertion_options -net_uniquification_suffix` command.

- `-treat_common_ancestor_as_unique` on | off

An optional switch and literal pair that specifies whether the `create_connections` command treats the common ancestor module of a one-to-N connection as unique. By default, the tool does not lift the connections as if the common ancestor is unique (that is, instantiated only once). This results in the same one-to-N connections being made in all instances of the common ancestor module. This is the setting used when instantiating the instruments as part of the `process_dft_specification` command.

When set to off, the connection is lifted above the common ancestor if the common ancestor is non-unique and the connection does not include all repeated instances of the destinations. This enables the remaining destinations to be connected to a different source. This functionality is only available when auto-uniquify is off.

When unspecified, the setting defaults to the value set in the “[set_insertion_options -treat_common_ancestor_as_unique](#)” command.

- `-silent`

An optional argument that specifies to ignore specified objects that do not exist and to not generate error messages. Connections with at least one non-existent object are skipped.

Examples

Example 1

The following example illustrates Usage 1 and creates a connection between three scalar ports and a 3-bit bus pin. The pin name created on u2 to route the connection is `u2_a[2:0]`. This pin name is constructed by concatenating the `leaf_instance_name` of `u1/u2/a` with the `leaf_name` of pin a with an underscore, because it has fewer than three characters.

```
create_connections u1/u2/a[2:0] {a b c}
```

Example 2

The following example illustrates Usage 2 and creates three connections between port IN1 and pins `blockA/modB/u1/a`, `blockA/modB/u2/a`, and `blockA/modC/u1/a`. The command creates a single net called `myname` on `u1`, `u1/u1` to make all three connections.

```
create_connections IN1 {blockA/modB/u1/a blockA/modB/u2/a blockA/modC/u1/a} \  
-net_name myname
```

Example 3

The following example illustrates Usage 3 and connects all pins matching the name ABC*/TE to a constant 0 value.

```
create_connections [get_pins ABC*/TE -hier] -constant 0
```

Example 4

The following example illustrates Usage 2 and shows a one-to-N connection including Verilog generate loop statements. The ltest_to_en output on a module outside the generate loop is broadcast to the LV_TM inputs on instances inside two different generate loops.

```
create_connections {  
  TOP_rtl_tessent_mbist_bap_inst/ltest_to_en  
  TOP_rtl_tessent_mbist_bap_inst/ltest_to_en  
  TOP_rtl_tessent_mbist_bap_inst/ltest_to_en  
  TOP_rtl_tessent_mbist_bap_inst/ltest_to_en  
}  
{  
  param_parent_genloop2_l/child_genloop[0].memory_interface_inst/LV_TM  
  param_parent_genloop2_l/child_genloop[1].memory_interface_inst/LV_TM  
  param_parent_genloop3_l/child_genloop[0].memory/memory_interface_inst/LV_TM  
  param_parent_genloop3_l/child_genloop[1].memory/memory_interface_inst/LV_TM  
}
```

create_custom_bisr_register

Context: dft

Mode: setup

Creates a customized BISR register that is manually instantiated by the user in the functional design and is used to control functional logic.

Usage

```
create_custom_bisr_register register_name [-size integer] [-output_directory output_dir]  
    [-rtl_extension rtl_extension] [-so_retiming on | off] [-replace]
```

Description

The `create_custom_bisr_register` command creates a BISR register with the specified **register_name**. An example implementation may be where the custom BISR register is used to control functional logic that configures memory read/write margins.

The command generates the RTL and ICL files for the BISR register and places them in the directory specified by the `-output_directory` property. You must manually instantiate the register in the functional design after it is generated, prior to running DFT insertion. When you run the [check_design_rules](#) command, Tessent Shell identifies the custom BISR register instances and lists them inside the `.bisr_segment_order` file, as specified by the [MemoryBisr](#) wrapper in the `DftSpecification`. During `process_dft_specification`, the custom BISR registers in the design are combined into the BISR chains, along with the other BISR registers that are used for memory repair.

The size of the custom BISR registers should be kept comparable to the size of the BISR registers used for memory repair, and if there are several, the default value should be “0” in most cases. The objective is to keep a low density of bits requiring the value “1”, to minimize the impact on the number of fuses required to store information. Refer to the “[Compression Algorithm and Fuse Box Organization](#)” section for additional information. Information requiring large custom registers or a large number of custom registers that would cause a high density of 1s, should be stored directly in the fuse box using the TAP access mode described in “[FuseBox Access](#)” rather than using the autonomous `self_fuse_box_program` operation.

The contents of the BISR register can be loaded serially using the `PatternsSpecification MemoryBisr bisr_chain_access` run mode. Data can be captured from the BISR register D input ports with `load_bisr_chain` operation, which is run in the `MemoryBisr` autonomous run mode. The contents of the custom BISR register is compressed into the fuse box during the `self_fuse_box_program` autonomous operation. During a power-up, the contents of the fuse box is decompressed and the values of the custom BISR register are restored.

Arguments

- **register_name**

A required string pair that specifies the name of the custom BISR register.

- *-size integer*
An optional switch and integer pair that specifies the number of bits contained within the custom BISR register.
- *-output_directory output_dir*
An optional switch and string pair that specifies the output directory where the RTL and ICL file are written. If not specified, the default location is the current directory.
- *-rtl_extension rtl_extension*
An optional switch and string pair that specifies the extension for the Verilog RTL file. If not specified, the “.v” extension is used.
- *-so_retiming on | off*
An optional switch and boolean pair that specifies whether the final output of the custom BISR pipeline register has a negedge register before the scanout port of the custom BISR pipeline module. This is the default configuration.

The presence of the negedge register reduces setup margin by half a clock period, however it simplifies the BISR hold timing closure with the addition of a half clock period of margin. You should only need a BISR pipeline register without the final negedge register in special cases where you do not meet setup timing closure due to excess delay from the transmitting BISR register to the receiving register. Additionally, when the negedge register is not present, it is mandatory to balance the BISR clock throughout the design to control skew and avoid hold time closure issues.
- *-replace*
An optional switch that overwrites any existing files when specified.

Examples

The following example shows the creation of a custom BISR register named “user_bisr” that is 32 bits wide. The Verilog RTL and ICL files for the register are populated in the current directory and the default extension is used for the Verilog RTL file.

```
SETUP>create_custom_bisr_register usr_bisr -size 32
//      Generating design files for BISR module usr_bisr
//      Verilog RTL : ./usr_bisr.v
//      IJTAG ICL   : ./usr_bisr.icl
SETUP>
```

create_dft_specification

Context: dft (with no sub context)

Mode: analysis

Creates the DftSpecification(*design_name,id*) configuration wrapper and returns the newly created wrapper object so that it can be stored in a variable and used to customize the created specification.

Usage

```
create_dft_specification [-existing_ijtag_host_scan_in host_scan_in_design_pin_spec]  
  [-existing_primary_tap_scan_out tap_client_scan_out_design_pin_spec]  
  [-existing_bscan_host_scan_in bscan_host_scan_in_design_pin_spec]  
  [-tile_ijtag_host_list tile_ijtag_hosts]  
  [-active_high_compliance_enables enable_port_name ...]  
  [-active_low_compliance_enables enable_port_name ...]  
  [-sri_sib_list sri_sib_list]  
  [-sti_sib_list sti_sib_list]  
  [-replace]
```

Description

This command finds IJTAG instances in the design that need to be connected to the IjtagNetwork and automatically creates the IjtagNetwork wrapper to connect them. The command supports multiple DFT insertion passes into any given module. The tool excludes elements seen to already be connected to the network from the current specification. An IJTAG instance is automatically seen by the command if its ICL file was loaded and the ICL module was matched to the design module during elaboration. Refer to “[set_design_sources -format](#)” and the [set_module_matching_options](#) command descriptions for more details about this process. Use [report_ijtag_instances](#) or [get_ijtag_instances](#) to find which instances have a matched ICL module.

This command also creates the necessary IJTAG network to control created memory BIST and memory BISR controllers as well as providing a boundary scan host port to BoundaryScan. To create a DFT Specification for any of these three features, you must enable them in setup mode using the [set_dft_specification_requirements](#) command prior to issuing the [check_design_rules](#) command. Refer to the BoundaryScan sections, if you are not familiar with these flows. Even though they are documented in separate sections, you can insert all instrument types in one insertion pass or in successive passes. The tool supports both methods and is simply controlled by what options you use with the [set_dft_specification_requirements](#) command prior to issuing the [check_design_rules](#) command.

Note

 If you have used [add_dft_signals](#) scan_en to define top level ports as DFT signals of type scan_en, it is automatically added to the [AdvancedOptions/ConstantPortSettings](#) wrapper such that the scan enable signals are automatically asserted off during the pattern generation. If you have other scan enable ports not identified with the add_dft_signals, you must add them yourself in the create [PatternsSpecification](#).

Note

 If you want to perform boundary scan insertion and TAP insertion pointing directly to internal pins instead of top-level ports, refer to the instructions in [Example 2](#) of the [IjtagNetwork](#) wrapper section.

How the IjtagNetwork Specification is Created

The [set_design_level](#) command is used to define the target usage level of the current design. When the level is set to “physical_block” or “sub_block”, the IJTAG interface created by the create_dft_specification command is a client IJTAG interface. When the level is set to “chip”, it is a client TAP interface. The TAP interface port names can be set by create_dft_specification if the ports are identified with the [Port](#) built-in attribute “function” set to tdi, tdo, tms, tck, or trst. If a port function is not set, then create_dft_specification reverts to the [DefaultsSpecification](#) value or the default value of the property.

For the first dft insertion pass containing any IJTAG component, a root level IJTAG ring is created with one or two Sibs in series. The two sibs are called Sib(sti) and Sib(sri) and are inserted on demand when needed by the current insertion pass if it was not already inserted by a prior insertion pass. The Sib(sti) provides access to the IJTAG network for all instruments in the current design that are to be scan tested along with the rest of the functional logic by the logictest modes such as EDT or logicBIST. The acronym “sti” refers to “Scan Tested Instrument”. As shown in [Figure 10-14](#), that Sib provides isolation between its host port and its clients. The Sib(sri) is used to provide access to the IJTAG network for child physical blocks, and for logictest instruments and Tdrs used to configure the logictest modes. The acronym “sri” refers to “Scan Resource Instrument”. These IJTAG nodes must remain active and undisturbed during the logictest modes, and are excluded from the logictest scan chains.

An ICL module is identified as a Scan Resource Instrument when it has the ICL module attribute called keep_active_during_scan_test set to “true”, which is the default, and that the instrument is treated as a Scan Resource Instrument and placed under the Sib(sri). If you have an instrument that you want to be tested like any other functional logic during scan test, you must specify the keep_active_during_scan_test attribute to “false” in its ICL module.

At the chip level, a TAP controller is inserted on the first insertion pass unless the -existing_ijtag_host_scan_in option of the create_dft_specification command has been used to reference a design pin. The design pin must be on an instance having an associated ICL module and the pin must be a ScanInPort referenced by a Host ScanInterface wrapper. Those different scenarios are illustrated in the [Example 1](#) section below.

Any instance of a module having a corresponding ICL module is, by default, inserted into the IjtagNetwork wrapper of the DftSpecification unless it is seen as being already connected to the network. The [set_ijtag_instance_options](#) command or the `tessent_use_in_dft_specification icl_module` attribute can be used to change the default behavior.

Different ICL elements (ScanInterfaces, DataInPorts, and DataOutPorts) seen in the circuit are handled by this command as described here:

- **Client ScanInterface** — A Client ScanInterface is referenced by a [DesignInstance](#) wrapper when it is to be inserted into the network as part of the current DftSpecification. It is not referenced by the current IjtagNetwork when the ScanInPort associated to the Client ScanInterface has its attribute “has_functional_source” set to true. You can use the [set_ijtag_instance_options](#) command to force its inclusion or exclusion independent of the value of the `has_functional_source` attribute.

If the ScanInterface is on an instance that is defined as a physical block (as defined by the `tessent_is_physical_module` attribute of its ICL module), it is inserted below the Sib(sri).

If the ScanInterface is on an instance that is not defined as a physical block (as defined by the `tessent_is_physical_module` attribute of its ICL module), it is inserted behind the Sib(sti) or Sib(sri) based on the value of the `keep_active_during_scan_test` attribute on its ICL module.

If you have read in UPF or CPF descriptions using the [read_upf](#) or [read_cpf](#) commands, the information is used to make sure that groups of DesignInstances associated to different power domains are isolated by a SIB. This is done to avoid daisy chaining them with elements from a different power domain and running into issues when accessing the elements in a given power domain while the other power domains are off.

- **DataInPorts** — A DataInPort is referenced by a connection property inside the Tdr/DataOutPorts wrapper when it is to be controlled by the network. The DataInPort is not referenced by the current IjtagNetwork when there is already a DataOutPort or a primary input port in its fanin or the DataInPort has the `icl_port` the [tessent_use_in_dft_specification](#) attribute set to “false”. If the `tessent_use_in_dft_specification` attribute is set to “auto_no_pi”, the port is sourced by a TDR port even if it is sourced by a primary input port. Use this value on special ports like the reset port of a PLL or clock divider to make sure it is locally controllable by IJTAG. This concept is further explained in the [ProcedureStep](#) wrapper section of the [PatternsSpecification](#) chapter. It contains a complete example of a clock divider re-used by memory BIST and initialized by IJTAG. If the DataInPort has a functional source, a multiplexer is inserted to control the DataInPort by the IjtagNetwork in test mode without disturbing its functional source its mission mode. Use the [set_ijtag_instance_options](#) command to force its inclusion or exclusion independent of whether it has a DataOutPort in its fanin.

If the instance on which the DataInPort exists has the `keep_active_during_scan_test` attribute defined and set to “true”, the Tdr sourcing the DataInPort is inserted behind the

Sib(sri) so that it is kept active and not part of the scan chain during the scan test modes. If the `keep_active_during_scan_test` attribute is “false”, then the Tdr sourcing the DataInPort is inserted behind the Sib(sti) so that it can be scan tested along with the rest of the functional logic.

The reset value of the TDR bits are determined first by the constant tie value of the design pin, or second by the ICL attribute `default_load_value` of the ICL description of that port if the design pin is not tied. The reset value defaults to 0 if none of these conditions are found.

You can use the `tessent_enable_group` attribute to group the DataInPorts into arbitrary groups. One Tdr is inserted per enable group enabling the multiplexers to be switched to the IJTAG side independently for each group to take control of one group of ports while leaving the others under functional control.

You can also use the `tessent_common_tdr_source` attribute to drive the DataInPorts from a single TDR bit. Every unique source name creates a new DataOutPort on a single TDR across all design instances. If the `tessent_enable_group` is also specified, a new TDR is created for each group to drive all the common sources of that group.

- **DataOutPorts** — A DataOutPort is referenced by a connection property inside the Tdr/DataInPorts wrapper when it is to be observed by the network. It is not referenced by the current IjtagNetwork when there is already a DataInPort in its fanout or the DataOutPort has the `icl_port` attribute `tessent_use_in_dft_specification` set to “false”. You can use the [set_ijtag_instance_options](#) command to force its inclusion or exclusion independent of whether it has a DataInPort in its fanout.

If the instance on which the DataOutPort exists has the `icl_port` attribute defined and set to true, the Tdr observing the DataOutPort is inserted behind the Sib(sri) so that it is kept active and not part of the scan chain during the scan test modes. If the `keep_active_during_scan_test` attribute is “false”, then the Tdr observing the DataOutPort is inserted below the Sib(sti) so that it can be scan tested along with the rest of the functional logic.

Licensing

This command normally requires an IJTAG product license to run but there is one exception to this requirement. If the design contains one or more instances of an EDT/LBIST controller, the Tessent TestKompress/LogicBIST licenses are also permitted to run this command. In this case, the tool checks the availability of the license in the following order: IJTAG, Tessent TestKompress, LogicBIST. If none are currently available, the tool queues up for all three and uses the first license that becomes available.

You can refer to the [set_license_queue_timeout](#) and [get_license_queue_timeout](#) commands for more information about the license queuing feature.

Arguments

- `-existing_ijtag_host_scan_in` *host_scan_in_design_pin_spec*

An optional switch and value pair that defines an existing host scan interface to which the entire IjtagNetwork should attach to inside the created [DftSpecification](#). The design pin must be on an instance having an associated ICL module and the pin must be a ScanInPort referenced by a Host ScanInterface wrapper. Specify this option during the first insertion pass. When unspecified, the interface to the ijtag network is determined using several criteria. When it is not the first insertion pass into the current design and either the Sib(sti) or the Sib(sri) is seen, it is automatically used as the connection point for the current insertion pass as illustrated in step 2 of the example below. If it is the first insertion pass, a TAP is inserted to host the root level Sib ring when design level is “chip”. The root level Sib ring is connected to ports when at the `physical_block` or `sub_block` level. The design level is specified as `chip`, `physical_block` or `sub_block` using the [set_design_level](#) command.

- `-existing_primary_tap_scan_out` *tap_client_scan_out_design_pin_spec*

An optional switch and value pair specifying that a current TAP client interface is to be used as primary instead of creating a new one. It can only be used when the design level is “chip”.

If other TAP or ijtag client interfaces, or if the dft requirements need additional ijtag nodes and this option is specified, you must also specify the `-existing_ijtag_host_scan_in` switch and value pair.

If the option is not used, the tool creates a TAP as the primary TAP and additional TAP client interfaces already in the design are muxed — refer to “[Tap](#)” on page 3790 for more information. Each additional TAP client interface adds one scanMux and one DataOutPort in a new TDR (only a single TDR for many TAP client interface, 1 bit for each TAP.)

- `-existing_bscan_host_scan_in` *bscan_host_scan_in_design_pin_spec*

An optional switch and value pair that defines an existing host bscan interface to which the boundary scan chain is to connect to. You typically do not need to specify this option. This switch value and value pair is mutually exclusive with the following switches:

- `-active_high_compliance_enables`
- `-active_low_compliance_enables`

If no TAP already exists in the design and the `set_design_level` command was used to specify level “chip”, a [Tap](#) wrapper is automatically inserted in the [IjtagNetwork](#) wrapper to host both the ijtag network and the boundary scan chain. If a TAP controller was inserted in a previous insertion pass and you did not delete the HostBscan wrapper, it is automatically seen and the boundary scan chain is automatically hooked up to it. If you have your own third-party TAP controller and you described it with an ICL file as described in section [BoundaryScan](#) it too is recognized by the command and the boundary scan chain is automatically hooked up to it.

You specify this option if you have more than one TAP controller already present in the design that meets the requirements described in “[BoundaryScan](#)” on page 3901. You also

need to specify this option if the ICL description of your TAP does not call the ScanInterface associated with the host bscan interface named “bscan” exactly.

For example, the LogicVision TAP can be used to host the boundary scan chain, but if it was generated prior to version 2014.2, the ScanInterface for the boundary scan chain was not called “bscan”. In this case, you need to point to the “fromBscan” pin of the TAP using the `-existing_bscan_host_scan_in` option in order to have `create_dft_specification` command connect the boundary scan register to it.

- `-tile_ijtag_host_list` *tile_ijtag_hosts*

An optional switch and value pair that specifies a list of tile host ports to add to the IJTAG network of this insertion pass. The `tile_ijtag_hosts` value is a TCL list composed of names. Use this option if the current design is a tile that should connect to neighboring tiles. The order of the list is important. The tool daisy-chains the hosts in the order found in the list, where index 0 of the list will be on the `scan_out` side, and the max index will be on the `scan_in` side. The tool will add a pipelining host SIB for each host port.

- `-active_high_compliance_enables` *enable_port_name ...*

An optional switch and value pair that defines one or more ports that need to be set to 1 in order to access the TAP scan path that are created with the resulting DftSpecification.

Use this option to create a Tessent TAP that shares the ports with a pre-existing connected TAP, which may or may not have an ICL description. This option can only be specified when design level is “chip” and cannot be used with `-existing_bscan_host_scan_in`, `-existing_ijtag_host_scan_in`, or `-existing_primary_tap_scan_out` options.

For more information, refer to the [HostScanInterface](#) wrapper’s `active_high_compliance_enables` property and also “[Example 3](#)” on page 3737.

Note

 If the compliance enabling logic is already present in your design and you want to connect the TAP to it, follow the instructions described in [Example 2](#) of the [IjtagNetwork](#) wrapper section.

- `-active_low_compliance_enables` *enable_port_name ...*

An optional switch and value pair that defines one or more ports that need to be set to 0 in order to access the TAP scan path that are created with the resulting DftSpecification.

Use this option to create a Tessent TAP that shares the ports with a pre-existing connected TAP that may or may not have an ICL description. This option can only be specified when design level is “chip” and cannot be used with `-existing_bscan_host_scan_in`, `-existing_ijtag_host_scan_in`, or `-existing_primary_tap_scan_out` options.

Note

 If the compliance enabling logic is already present in your design and you want to connect the TAP to it, follow the instructions described in [Example 2](#) of the [IjtagNetwork](#) wrapper section.

- `-sri_sib_list sri_sib_list`
An optional switch and value pair that specifies a list of string ID that is used to create Sib(id) wrappers in the created IjtagNetwork wrapper. The Scan Resource Instrument host Sib is created if not already present. If it is already present, it is referenced using the HostScanInterface wrapper and the requested Sibs are inserted below it. This option is useful if you want to add your own instrument inside the network and this instrument needs to remain active during scan test. This option provides the host for your instrument in the created DftSpecification. This option is also useful to create a host for the OCC controllers. You run `create_dft_specification` with `-sri_sib_list occ` option, then you simply specify the `host_scan_interface` property in the OCC wrapper to Sib(occ) as shown in Example 2 below.
- `-sti_sib_list sti_sib_list`
An optional switch and value pair that specifies a list of string ID that is used to create Sib(id) wrappers in the created IjtagNetwork wrapper. The Scan Tested Instrument host Sib is created if not already present. If it is already present, it is referenced using the HostScanInterface wrapper and the requested Sibs are inserted below it. This option is useful if you want to add your own instrument inside the network and this instrument is to be tested as normal functional logic during scan test. This option provides the host for your instrument in the created DftSpecification.
- `-replace`
An optional switch that suppresses the error that normally occurs if the [DftSpecification](#)(*design_name*,*id*) configuration wrapper already exists in memory. Instead, the existing one is deleted and replaced by the newly created one.

Examples

Example 1

The following example illustrates the created DftSpecification that is generated by the `create_dft_specification` command when running on different modules of a chip. The examples below are useful to understand how instruments are connected to the IjtagNetwork in a multi-insertion pass scenario.

Step 1

The first run is performed on a core called CoreA to create and hook up instruments to the network. These instruments are scan testable (`keep_active_during_scan_test` is “false”). It is the first dft insertion pass involving the IjtagNetwork in that module so the tool creates the Sib(sti) in this run.

```
set_context dft -rtl  
#commands to load design appears here
```

```
set_current_design CoreA  
set_design_level physical_block
```

```
set_system_mode analysis
```

```
set spec [create_dft_specification]
```

The generated DftSpecification is shown below. The Sib(sti) is identified with the “tessent_dft_function” attribute set to “scan_tested_instrument_host”. All local scan interfaces are daisy chained below the Sib(sti_local).

```
DftSpecification(CoreA,rtl) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Sib(sti) {
        Attributes {
          tessent_dft_function : scan_tested_instrument_host;
        }
        Sib(sti_local) {
          DesignInstance(tdr_1) {
            scan_interface : client;
          }
          DesignInstance(tdr_1) {
            scan_interface : client;
          }
        }
      }
    }
  }
}
```

Step 2

The second run is again performed on the core called CoreA at a later time to insert a Tdr used to control DataInBits on a scan control module that was user-inserted after the original insertion phase. The scan control module has an associated ICL file that documents its DataInPorts and with the ICL module attribute `keep_active_during_scan_test` set to “true”. Notice that because this is a second insertion pass into the same design module, the *design_id* is specified as rtl2 in the `set_context` command to differentiate the insertion pass from the previous one. An error would have been generated had it not been specified because a conflict would have been noticed from the existence of instances of module names whose names start with “CoreA_rtl_tessent_”.

```
set_context dft -rtl -design_id rtl2  
#commands to load design appears here
```

```
set_current_design CoreA  
set_design_level physical_block
```

```
set_system_mode analysis
```

```
set spec [create_dft_specification]
```

The generated DftSpecification is shown below. The Interface wrapper of the HostScanInterface wrapper is used to specify that the new Sib(sri) is to be inserted in series with the client interface of the Sib instance “CoreA_rtl_tessent_sib_sti_inst”, which is the Sib(sti) created in the first insertion pass.

```
DftSpecification(CoreA,rtl2) {
  IjtagNetwork {
    HostScanInterface(sri) {
      Interface {
        design_instance : CoreA_rtl_tessent_sib_sti_inst;
        scan_interface : client;
      }
      Sib(sri) {
        Attributes {
          tessent_dft_function : scan_resource_instrument_host;
        }
        Sib(sri_local) {
          Tdr(sri_tdr1) {
            DataOutPorts {
              connection(0) : scan_control_inst/tm;
              connection(1) : scan_control_inst/ac_mode;
              connection(3:2) : scan_control_inst/config[1:0];
            }
          }
        }
      }
    }
  }
}
```

Step 3

The third run is performed on the chip called ChipA. It is used to provide access to the IJTAG scan interface of the 2 instances of CoreA and to again insert a Tdr to control the data_in ports of the scan control module situated at the top level. A Tap wrapper is created as the -existing_ijtag_host_scan_in option was not specified and the Tap from a previous insertion pass was not seen as this is the first insertion pass at the chip level.

```
set_context dft -rtl  
#commands to load design appear here
```

```
set_current_design ChipA  
set_design_level chip  
set_attribute_value [get_ports TCK_p] -name function -value tck  
set_attribute_value [get_ports TDI_p] -name function -value tdi  
set_attribute_value [get_ports TDO_p] -name function -value tdo  
set_attribute_value [get_ports TMS_p] -name function -value tms  
set_attribute_value [get_ports TRST_p] -name function -value trst  
set_system_mode analysis
```

```
set spec [create_dft_specification]
```

The generated DftSpecification is shown below. Note how a Tap wrapper is being specified. It includes a HostBscan wrapper such that the TAP is ready for boundary scan-in a future insertion pass. One sib is inserted into the root level Sib ring to interface to the two instances of CoreA, and to provide access to the Tdr that is inserted to control the DataIn ports of the scan control module. Each child physical block is also wrapped by a local Sib to make sure other parts of the network are always accessible even if the physical block is defective, powered down, or in simulation, black-boxed.

```

DftSpecification(ChipA,rtl) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Interface {
        tck : TCK_p;
        trst : TRST_p;
        tms : TMS_p;
        tdi : TDI_p;
        tdo : TDO_p;
      }
      Tap(main) {
        HostBscan {
        }
        HostIjtag(1) {
          Sib(sri) {
            Attributes {
              tessent_dft_function : scan_resource_instrument_host;
            }
            Sib(pb1) {
              DesignInstance(CoreA_I1) {
                scan_interface : ijtag;
              }
            }
            Sib(pb2) {
              DesignInstance(CoreA_I2) {
                scan_interface : ijtag;
              }
            }
            Sib(sri_local) {
              Tdr(sri_tdr1) {
                DataOutPorts {
                  connection(0) : scan_control_inst/tm;
                  connection(1) : scan_control_inst/ac_mode;
                  connection(2) : scan_control_inst/config2;
                }
              }
            }
          }
        }
      }
    }
  }
}

```

Step 3 under [Example 1](#) could have been modified to connect to an existing TAP controller by simply using the `-existing_ijtag_host_scan_in` option as follows:

create_dft_specification -existing_ijtag_host_scan_in mytap/from_bist0

The created DftSpecification would then be as follows:

```
DftSpecification(ChipA,rtl) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Interface {
        DesignInstance (mytap)
        scan_interface : BistPort0;
      }
      Sib(sri) {
        Attributes {
          tessent_dft_function : scan_resource_instrument_host;
        }
        Sib(pb1) {
          DesignInstance(CoreA_I1) {
            scan_interface : ijtag;
          }
        }
        Sib(pb2) {
          DesignInstance(CoreA_I2) {
            scan_interface : ijtag;
          }
        }
        Sib(sri_local) {
          Tdr(sri_tdr1) {
            DataOutPorts {
              connection(0) : scan_control_inst/tm;
              connection(1) : scan_control_inst/ac_mode;
              connection(2) : scan_control_inst/config2;
            }
          }
        }
      }
    }
  }
}
```

Example 2

This example shows how the `-sri_sib_list` option is used to create a host node for the OCC wrapper. The OCC wrapper makes reference back to the `Sib(occ)` using the `ijtag_host_interface` property.

```
set spec [create_dft_spec -sri_sib_list occ]
report_config_data $spec
```

```

DftSpecification(corea,gate) {
  use_rtl_cells : on;
  IjtagNetwork {
    ImplementationOptions {
      scan_path_retiming : flop;
    }
    HostScanInterface(ijtag) {
      Sib(sti) {
        Attributes {
          tessent_dft_function : scan_tested_instrument_host;
        }
      }
      Sib(sri) {
        Attributes {
          tessent_dft_function : scan_resource_instrument_host;
        }
        Sib(sri_ctrl) {
          Tdr(sri_ctrl) {
            Attributes {
              tessent_dft_function : scan_resource_instrument_dft_control;
            }
          }
        }
      }
      Sib(occ) {
      }
    }
  }
}

```

```

read_config_data -in_wrapper $spec -from_string {
  Occ {
    ijtag_host_interface : Sib(occ);
    Controller(c1) {
      clock_intercept_node : clk;
    }
  }
}

```

Example 3

The following example runs a script to push down each Tdr wrapper below its own Sib wrapper when there are more than one below the Sib(sti_local) or Sib(sri_local) wrapper.

```
proc push_tdr_below_sibs {spec} {
# Only works if the spec was created by create_dft_specification.
set sib_locals [get_config_elements Sib(*_local) -below $spec -hier -silent]
foreach_in_collection sib_local $sib_locals {
set tdrs [get_config_element Tdr -below $sib_locals -silent]
if {[sizeof_collection $tdrs] > 1} {
foreach_in_collection tdr $tdrs {
set id [get_config_value $tdr -id <0>]
set sib [add_config_element Sib(sib_{$id}) -in $sib_local]
#Place New Sib in same parent instance as the TDR
unset pin
if {[get_config_value DataOutPorts/connection(0) -in $tdr -exist]} {
set pin [get_config_value DataOutPorts/connection(0) -in $tdr]
} elseif {[get_config_value DataInPorts/connection(0) -in $tdr -exist]} {
set pin [get_config_value DataInPorts/connection(0) -in $tdr]
}
if {[info exists pin]} {
set parent_instance [get_attribute_value [get_pins [list $pin]] \
-name parent_instance]
}
if {$parent_instance ne ""} {
set_config_value parent_instance -in $sib $parent_instance
set_config_value parent_instance -in $tdr $parent_instance
move_config_element \
[get_config_value parent_instance -in $tdr -object]-first
}
move_config_element $tdr -in $sib
}
}
}
}
}
set spec [create_dft_specification]
push_tdr_below_sibs $spec
```

Here is the Tdr wrapper before and after it was pushed below its own Sib Wrapper.

Before:

```
Tdr(sri_tdr4) {
DataOutPorts {
connection(0) : sub1_i2/sub2_i2/sub3_i1/di[0];
connection(1) : sub1_i2/sub2_i2/sub3_i1/di[1];
connection(2) : sub1_i2/sub2_i2/sub3_i1/di[2];
connection(3) : sub1_i2/sub2_i2/sub3_i1/di[3];
connection(4) : sub1_i2/sub2_i2/sub3_i1/di[4];
}
}
```

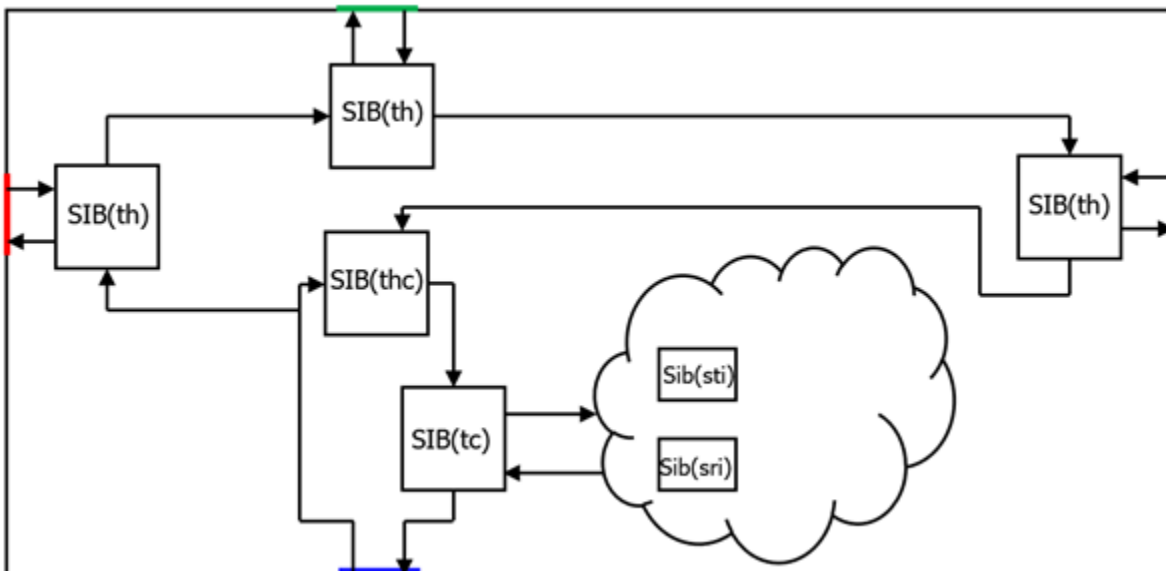

After:

```
Sib(sib_sri_tdr4) {
  parent_instance : sub1_i2/sub2_i2;
  Tdr(sri_tdr4) {
    parent_instance : sub1_i2/sub2_i2;
    DataOutPorts {
      connection(0) : sub1_i2/sub2_i2/sub3_i1/di[0];
      connection(1) : sub1_i2/sub2_i2/sub3_i1/di[1];
      connection(2) : sub1_i2/sub2_i2/sub3_i1/di[2];
      connection(3) : sub1_i2/sub2_i2/sub3_i1/di[3];
      connection(4) : sub1_i2/sub2_i2/sub3_i1/di[4];
    }
  }
}
```

Example 4

The following example shows how to use the “-tile_ijtag_host_list *tile_ijtag_hosts*” switch to create a DftSpecification suitable for a tiled design. In [Figure 3-27](#), SIB(tc) is the tile client for all IJTAG instruments in the core. It has a scan-in buffer stage but does not have a scan-out retiming latch. SIB(tc) connects in series with the tile host collector SIB(thc). The tool creates a tile host SIB(th) for each new tile host port specified in the *tile_ijtag_hosts* list. Each SIB(th) has a scan-in pipelining stage and is hosted by the tile host controller SIB(thc).

Figure 3-27. Design with IJTAG Host Tiling

```
set_dft_specification_requirements -design_type tile
check_design_rules
set_spec [create_dft_specification -tile_ijtag_host_list {left top right}]
report_config_data $spec
```

```

DftSpecification(tile_core,gate)
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Sib(tc) {
        Attributes {
          tessent_dft_function : tile_client_sib;
        }
        to_scan_in_feedthrough : buffer;
        so_retiming : off;
        Sib(sti) {
          [...]
        }
        Sib(sri) {
          [...]
        }
      }
    }

    Sib(thc) {
      Attributes {
        tessent_dft_function : tile_host_collector;
      }
      Sib(th_right) {
        to_scan_in_feedthrough : pipeline;
        SecondaryHostScanInterface(right) {
        }
      }
      Sib(th_top) {
        to_scan_in_feedthrough : pipeline;
        SecondaryHostScanInterface(top) {
        }
      }
      Sib(th_left) {
        to_scan_in_feedthrough : pipeline;
        SecondaryHostScanInterface(left) {
        }
      }
    }
  }
}

```

create_diagnosis_patterns

Context: patterns -scan_diagnosis

Mode: analysis

Creates targeted patterns for logic failure or scan chain failure iterative diagnosis.

Usage

Logic Failure Diagnosis

```
create_diagnosis_patterns [-DIAGNosis_report {diagnosis_report1 diagnosis_report2 ...}]  
[-MAX_pattern_count number] [{-TRAnsition | -STUCK}]
```

Scan Chain Failure Diagnosis

```
create_diagnosis_patterns [-DIAGNosis_report {diagnosis_report}] [-CHAIN chain_name  
[-CELL_range lowerbound upperbound] [-FAULT_type {stuck_at_0 | stuck_at_1 |  
slow_to_rise | slow_to_fall | slow | fast_to_rise | fast_to_fall | fast}] ]
```

Description

For usage cases using this command, refer to “[Iterative Logic Diagnosis Examples](#)” in the *Tessent Diagnosis User’s Manual*. You can use iterative diagnosis with the layout-aware diagnosis flow as long as you use the layout in the same iterative diagnosis session—see “[Layout-Aware Diagnosis](#)” in the *Tessent Diagnosis User’s Manual*.

Note

After issuing this command, you should write out the test patterns to an external file using the `write_patterns` command.

Logic Failure Diagnosis: The tool loads the diagnosis result from a prior run or a diagnosis report file, create a fault list, and generates the patterns targeting suspect signals in the diagnosis report.

Scan Chain Failure Diagnosis: The tool loads either of the following inputs you specify:

- A diagnosis report file containing the diagnosis results of scan chain failure.
- The chain names, scan cell range, and the fault type.

For scan chain failure diagnosis, you can also provide a chain name (using the `-chain` switch) and a diagnosis report containing multiple faulty scan chains. In this case, the diagnostic test generation only creates patterns for the scan chain specified by the `-Chain` switch.

Arguments

Logic Failure Diagnosis Arguments

- **-DIAGnosis_report** {*diagnosis_report1 diagnosis_report2 ...*}
An optional switch and one or more strings that specifies the diagnosis report file(s) to be targeted by diagnostic ATPG. By default, the tool uses the diagnosis results from previous diagnosis run. You can also supply more than one diagnosis report for suspects from multiple diagnosis report files are targeted in one diagnosis test generation run. The diagnosis report must be in the default ASCII format.
- **-MAX_pattern_count** *number*
An optional switch and integer pair that specifies the maximum pattern count the tool generates. The default is no limit. Use when ATPG run time is a concern. The limit defined by **-MAX_pattern_count** is applied per chain if used for chain pattern generation.
- **-TRAnsition**
An optional switch that specifies creating transition test patterns. By default, the transition patterns generated are launch off capture (equivalent to the old `no_shiftlaunch` option).
- **-STUCK**
An optional switch that specifies creating create stuck-at diagnosis patterns.

Scan Chain Failure Diagnosis Arguments

- **-DIAGnosis_report** {*diagnosis_report*}
An optional switch and string pair that specifies the diagnosis report file to be targeted by diagnostic ATPG. By default, the tool uses the diagnosis results from previous diagnosis run. Note that only a single diagnosis report is permitted as input for chain failures.
- **-CHAIN** *chain_name*
An optional argument and string pair that specifies a single chain.
- **-CELL_range** *lowerbound upperbound*
An optional argument and pair of integers for the **-chain** option that specifies the beginning and ending of a range of cells.
- **-FAULT_type** {*stuck_at_0 | stuck_at_1 | slow_to_rise | slow_to_fall | slow | fast_to_rise | fast_to_fall | fast*}
An optional argument and literal pair for the **-chain** option that specifies the fault type.

create_feature_statistics

Context: patterns -scan_diagnosis

Mode: analysis

Calculates the root cause deconvolution (RCD) constants from the LDB for RCD diagnosis and analysis.

Usage

```
create_feature_statistics [-temp_dir dir_name] [-add_processors {hostname[:{cpus |  
MAXcpu}]}...] [-force]
```

Description

The tool analyzes the design for all possible diagnosis suspects for certain features in the layout. It determines which bridge pairs, net segments, and cells are tested, and extracts the relevant physical information such as the critical area, via count, and cell instance count for each possible suspect.

The tool also performs threshold ratio checking and returns information to warn you about low detection of the RCD root causes by fault simulation. This could indicate problems with the pattern file. The information is only issued if at least one cell, open, or bridge detected ratio is less than 10 percent.

You must create the RCD constants statistics for every flat model and pattern combination. To do this, you can process the combinations in parallel in different tool sessions.

RCD analysis in Tessent YieldInsight determines the probability sums for the features across the diagnoses and uses the RCD constants to normalize their weights to account for diagnosis noise.

To use this command, you must have previously loaded your patterns and opened a LDB. Otherwise, the tool issues an error message. The feature statistics are stored in the LDB for later use by Tessent YieldInsight RCD analysis. They are not used during the diagnosis process.

For more information, see “[Diagnosis for Root Cause Deconvolution Analysis](#)” in the *Tessent Diagnosis User’s Guide*.

Arguments

- `-temp_dir dir_name`
An optional switch and string pair that specifies a temporary directory to use for command execution.
- `-add_processors {hostname[:{cpus| MAXcpu}]}...`
An optional switch and string that specifies to run multiple processors in parallel on multiple machines to reduce the runtime for calculating the RCD constants. The tool calls the

`add_processors` command and uses a multithreading process as described for the [add_processors](#) command.

Although the `-add_processors` switch supports the same options as the `add_processors` command, for the best performance, specify the localhost with 8 processors.

- `-force`

An optional switch that specifies to delete from the LDB the temp file or `.rcddb` file associated with the current flat model before attempting to generate feature statistics. This enables you to re-run RCD creation in the event of a premature termination, which can result in temporary locked files. The tool deletes the temp files, issues a warning and continues processing.

Examples

Example 1

The following example loads patterns and opens the layout before calculating the feature statistics.

```
read_patterns external my_test_patterns.wgl  
  
// Reading WGL input file "my_test_patterns.wgl"  
  
open_layout my_layout.db  
  
// DieArea: minx=-2107.000000, miny=-2002.000000, maxx=2107.000000,  
// maxy=2002.000000 in microns  
// Note: Checking layout consistency...  
// Note: Layout Database opened successfully.  
  
create_feature_statistics  
  
// Determining feature detection information  
// 10% Done.  
// 22% Done.  
.....  
// 100% Done.  
// Determining Open Feature Statistics  
// 11% Done.  
// 21% Done.  
.....  
// 100% Done.  
// Determining Bridge Feature Statistics  
// 13% Done.  
.....  
// Feature Statistics Calculation Complete. Information is written into  
// the layout database.
```

Example 2

The following example shows the message that the tool returns when you issue the `create_feature_statistics` when the feature statistics were previously calculated and stored in the LDB.

```
create_feature_statistics
```

```
// Note: Feature statistics for this flat model and pattern set have  
// already been calculated and stored in the layout database. There is no  
// need to perform this operation again.
```

Example 3

The following example shows the information that the tool returns when threshold ratio checking results in one or more cell, open, or bridge detected ratios that are less than 10 percent.

```
// detected cell ratio: 48.867  
// detected open ratio: 26.5447  
// detected bridge ratio: 81.2205  
// detected cells: 4162 opens: 19813 bridges: 60623  
// total cells: 8517 total nets: 74640
```

create_flat_model

Context: all contexts

Mode: setup

Creates a primitive gate simulation representation of the design. The command also flattens the hierarchy of the design so that the design can be viewed in the Tessent Visualizer Flat Schematic window.

Usage

```
create_flat_model
```

Description

The tool automatically flattens the design hierarchy down to the logically equivalent design when you exit Setup mode. However, there may be times that you would like to access the flat model without having to exit Setup mode. For example, you may want to add ATPG constraints and functions before you exit Setup mode.

If you exit Setup mode and then add ATPG constraints and functions, the design rule checker does not have access to those ATPG constraints during the rule checking. If you issue the `create_flat_model` command in Setup mode and then add those ATPG constraints, the design rule checker has access to them during the rule checking.

Note

 If you are preparing a flat model for later use in Tessent Diagnosis, save the flat model immediately after performing ATPG (issuing the `create_patterns` command) and saving final patterns. For more information, refer to “[Preparing the Design Netlist](#)” in the *Tessent Diagnosis User's Manual*.

Arguments

None

Examples

The following example shows flattening the design to the simulation primitives before adding constraints that the rule checker then uses when you run the design rule checker. The rule checker runs when you first attempt to exit Setup mode

```
create_flat_model
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 0 /i$135/q
add_atpg_constraints 1 and_b_in
set_system_mode analysis
```

The following example sets the system mode to setup, creates a flat model, and opens Tessent Visualizer:

```
set_system_mode setup  
create_flat_model  
open_visualizer
```

create_icl_flush_pattern

Context: patterns -silicon_insight -ijtag

Mode: setup

Creates an ICL flush pattern.

Usage

```
create_icl_flush_pattern pattern_name [-pattern_type {stil | svf}] [-bit_pattern {000..1 | 1..000}] [-bit_pattern_length value] [-scanout_skew value]
```

Description

Use the flush pattern to test the functionality of the IJTAG network for the configured scan path. This utility command is useful when you are creating your own algorithms to debug ICLNetwork test suspects.

Use this command when manually debugging IJTAG networks as described in “[Diagnosing and Debugging IJTAG Networks](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

This command creates a pattern file that flushes the specified bit pattern. The pattern is saved in a pattern file named *pattern_name.pattern_type*.

Arguments

- ***pattern_name***
A required string that specifies the name of the flush pattern to be generated.
- **-pattern_type {stil | svf}**
An optional switch and literal pair that specifies the pattern type: STIL or SVF. The default is SVF.
- **-bit_pattern {000..1 | 1..000}**
An optional switch and literal pair that specifies the type of bit pattern to generate. Two bit pattern types are supported: 000..1 and 1..000. The default is 000..1.
- **-bit_pattern_length *value***
An optional switch and value pair that specifies the length of the bit pattern to generate. The value must not be less than the current length of the configured scan path. The length is normally the same length of the scan path, which you can verify using the `get_icl_network -current_scan_path` command.
- **-scanout_skew *value***
An optional switch and value pair that skews the “1” in the specified bit pattern accordingly for the scanned-out bit pattern. If the bit pattern is “000..1”, the “1” s shifted to the left by the specified skew value. If the bit pattern is “1..000”, the “1” is shifted to the right by the specified skew value.

Examples

```
create_icl_flush_pattern my_flush
```

```
create_icl_flush_pattern my_flush_2 -bit_pattern 1..000 -bit_pattern_length 145 \  
-scanout_skew 5
```

create_icl_setup_pattern

Context: patterns -silicon_insight -ijtag

Mode: setup

Creates an ICL pattern to set up the scan path of interest in the current ICL network.

Usage

create_icl_setup_pattern *pattern_name* [-pattern_type {stil | svf}]

Description

When debugging an ICL network, use this command to generate a pattern file that, when you run it, sets up the ICL network to use the scan path that you have previously configured. This utility command is useful when you are creating your own algorithms to debug ICLNetwork test suspects.

Use this command when manually debugging IJTAG networks as described in “[Diagnosing and Debugging IJTAG Networks](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

The pattern is saved in a pattern file named *pattern_name.pattern_type*.

Arguments

- *pattern_name*
A required string that specifies the name of the setup pattern to be generated.
- -pattern_type {stil | svf}
An optional switch and literal pair that specifies the pattern type: STIL or SVF. The default is SVF.

create_icl_verification_patterns

Context: patterns -ijtag

Mode: analysis

Prerequisites: To use this command, you must have previously opened a pattern set with the `open_pattern_set` command.

Specifies the creation of a structural pattern to verify the proper operation of the IJTAG network.

Usage

```
create_icl_verification_patterns [-scan_test {on | off}]  
    [-data_pin_test {on | off | end_points_only}]  
    [-modules modules] [-exclude_modules exclude_modules]  
    [-instances instances] [-exclude_instances exclude_instances]  
    [-exclude_scan_registers exclude_scan_registers]  
    [-exclude_data_pins exclude_data_pins]
```

Description

In simulation, the pattern set is useful for identifying mismatches between the ICL and Verilog model views. In manufacturing test, the pattern set covers manufacturing defects that can exist in the IJTAG network circuitry. You do not need to use this command if you are using the more automated [create_patterns_specification/process_patterns_specification](#) flow. For more information about this flow, see the [ICLNetworkVerify](#) wrapper.

When you run this command with the `-scan_test` option set to `on`, the tool creates verification patterns by tracing backward from all ScanOutPorts and configuring all ScanMuxes found along the way; this exercises all scan configurations. On the first scan load, the predictably captured values of the ScanRegisters are compared and the scan registers are loaded with a pattern consisting of alternating sequences of 0s and 1s with an increasing sequence length. The TAP controller is then put in the pause state and the ScanRegisters are unloaded in a second scan load to make sure the same data comes out. This ensures that the ScanRegisters are actually the length documented in the ICL model.

When you set the `-data_pin_test` option to `on`, the tool forces any internal DataOutPorts that do not have a source described in ICL, and observes those values by ScanRegisters unloading. The tool controls internal DataInPorts that do not have a destination described in ICL using ScanRegisters loading, and directly observes the resulting value on the internal DataInPorts. This feature is only usable in simulation where it is useful for finding mismatches between the circuits and their ICL descriptions.

Arguments

- `-scan_test {on | off}`

An optional switch that specifies whether the patterns are to verify the integrity of the scan paths. When the option is set to `on`, which is the default, the tool creates the patterns by

tracing backward from all ScanOutPorts and configuring all ScanMuxes found along the way to exercise all scan configurations. On the first scan load, the predictably captured values of the ScanRegisters are compared and the scan registers are loaded with a pattern consisting of alternating sequences of 0s and 1s with an increasing sequence length. The TAP controller is then put in the pause state and the ScanRegisters are unloaded in a second scan load to make sure the same data comes out; this ensures that the ScanRegisters are actually the length documented in the ICL model. While shifting the scan path verification pattern out of the ScanRegisters, the next ICL network configuration is already shifted into the network.

```
load 101100111100001111111100000000... expect captures values described in ICL
load the next ICL network configuration expect 101100111100001111111100000000...
```

The ICL verification pattern generator uses two different strategies to create the patterns. First, it attempts to cover all paths with the previously discussed tracing strategy. If any ICL ScanRegisters cannot be covered with this method, the ICL verification pattern generator will attempt to target them with individual scan loads for testing.

- `-data_pin_test {on | off | end_points_only}`

An optional switch that specifies whether the patterns are to verify the values observed by Internal DataInPorts and controlled by internal DataOutPorts.

`end_points_only`—With this value, the internal DataOutPorts that do not have a source described in ICL are forced, and the forced values observed using the IJTAG network. The internal DataInPorts that do not have a destination described in ICL are controlled using the IJTAG network, and the resulting value is directly observed on the internal DataInPorts.

`On`—With this value, not only are the DataInPorts with no destination and the DataOutPorts with no source observed and controlled, but all DataInPorts having an observation path through the IJTAG network are forced in the test bench and observed by the IJTAG network to confirm that the ICL and HDL descriptions are consistent. Also, all DataInPorts having some controllability from the network are sensitized to a one and zero value and that value is directly observed on the DataInPort in the test bench.

`Off`—With this value, no force and compare are done on the DataInPorts and DataOutPorts.

Note that this feature is only usable in simulation where it is useful for finding mismatches between the HDL and associated ICL descriptions. For this feature to be usable, the ICL should have been created using `extract_icl` such that each ICL instance has the `tessent_design_instance` attribute defined to reflect the original design instance path associated to the ICL instance. Verifying the internal data pins can substantially increase the pattern count as well as the time to generate the verification patterns. The increase depends on the number of DataInPorts and DataOutPorts and the overall ICL network complexity.

Also, note that ICL Extraction sets the `tessent_design_instance` attribute to the pre-synthesis instance names whenever those names are available. During the creation of the data pin verification patterns, the actual design instance names are ignored. The verification pattern

generator only uses the `tessent_design_instance` attribute to obtain the references to the design pins. Consequently, the rtl design files provided to ICL extraction must be used during the simulation of the verification patterns, at least in case that the synthesis modifies the design hierarchy (for example, because of “generate” loops). To obtain data pin verification patterns that can be simulated using the synthesized netlist with instance names that have been modified by synthesis, you either have to modify the `tessent_design_instance` attributes accordingly or run ICL Extraction based on the synthesized netlist from the beginning (without providing rtl files to the tool).

- `-modules` *modules*

An optional switch that specifies the ICL modules the test should focus on. The `modules` parameter value contains glob patterns matching ICL module names instantiated below the current ICL design. For more information on glob pattern matching, refer to “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638.

- `-exclude_modules` *exclude_modules*

An optional switch that specifies the ICL modules the test should exclude. The `exclude_modules` parameter value contains glob patterns matching ICL module names instantiated below the current ICL design. For more information on glob pattern matching, refer to “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638.

ICL modules that have the `tessent_ignore_during_icl_verification` attribute set to on are automatically excluded. You can use this attribute on ICL modules that are not truly IJTAG compliant and cannot pass the structural test performed in this test. Tessent MemoryBIST ICL modules have the `tessent_ignore_during_icl_verification` attribute set to on and are automatically excluded from the `create_icl_verification_patterns` command. If a network verification of the MemoryBIST controller is needed, refer to the [PatternsSpecification MemoryBist/run_mode : setup_chain_test](#) property value description.

- `-instances` *instances*

An optional switch that specifies the only ICL instances the test should be performed on. The `instances` parameter value contains glob patterns matching ICL instances found below the current ICL design. For more information on glob pattern matching, refer to “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638.

- `-exclude_instances` *exclude_instances*

An optional switch that specifies the set of ICL instances to exclude from the test. The `exclude_instances` parameter value contains glob patterns matching ICL instances found below the current ICL design. ICL instances that have the `tessent_ignore_during_icl_verification` attribute set to on are automatically excluded.

- `-exclude_scan_registers` *exclude_scan_registers*

An optional switch that specifies the set of ICL scan registers to exclude from the test. The `exclude_scan_registers` parameter value contains glob patterns matching ICL instances found below the current ICL design. ICL Scan Registers that have the `tessent_ignore_during_icl_verification` attribute set to on are automatically excluded. This switch is used in the LogicBIST ICL module to exclude the single chain diagnostic registers

because they are too long to be simulated serially. This switch is only used when `-scan_test` is set to on.

- `-exclude_data_pins` *exclude_data_pins*

An optional switch that specifies the set of ICL pins to exclude from the data pin test. The `exclude_data_pins` parameter value contains glob patterns matching ICL pins found below the current ICL design. ICL DataInPorts and DataOutPorts that have the `tessent_ignore_during_icl_verification` attribute set to on are automatically excluded. This switch is only used when `-data_pin_test` is set to on.

Note

 The ICL verification pattern generator attempts to utilize a minimal scan path to reach all ICL instances which are to be tested by ICL verification patterns. This scan path might traverse ICL instances that have been excluded through the `-exclude_modules` or `-exclude_instances` switches. ICL modules with the “`tessent_ignore_during_icl_verification`” attribute are not considered when searching for a minimal scan path.

Examples

The following example loads an ICL file, generates ICL verification patterns, and writes out a simulation pattern file. Because this process is automated as part of the [create_patterns_specification](#) and [process_patterns_specification](#) flow, which also provides simulation automation using the [run_testbench_simulations](#) command, it typically does not need to be performed as shown here.

```
set_context patterns -ijtag
read_icl my_instrument.icl
set_current_design
set_system_mode analysis
open_pattern_set icl_verify
create_icl_verification_patterns -data_pin_test on
close_pattern_set
write_pattern icl_verify.v -verilog
```

[process_patterns_specification](#)
[run_testbench_simulations](#)

create_initialization_patterns

Context: dft -edt, patterns -scan

Mode: analysis

Creates RAM initialization patterns and places them in the internal pattern set.

Usage

```
create_initialization_patterns RAM_instance_name | RAM_gate_id#
```

Description

The `create_initialization_patterns` command creates RAM initialization patterns that write values into the specified RAM. The tool places these patterns into the internal pattern set from which you may save them into a file.

You can identify the RAM by its instance name or gate ID number. An error condition occurs if there is not a single RAM gate inside the instance or if the specified gate is not a RAM. An error condition also occurs if the RAM does not have an initialization file, or if the RAM did not successfully pass stability checking (Design Rules A1 and A6).

The tool creates the initialization patterns by doing an independent test generation for each valid address that has a non-X state on at least one data line. If the test generation aborts, the command terminates with an error message. The patterns contain a measure PO statement, but all values are X. There may also be an unload statement, but all values are X. If the patterns are re-simulated (as in pattern compression), the tool deletes patterns that do not detect faults. For those the tool does not delete, simulation values replace the Xs in the measure PO statement.

Arguments

- ***RAM_instance_name***
A string that specifies the instance name of the RAM for which you want to `create_initialization_patterns`.
- ***RAM_gate_id#***
An integer that specifies the gate identification number of the RAM for which you want to `create_initialization_patterns`.

Examples

The following example creates RAM initialization patterns for `p1.ram/u1`, places the patterns into the internal pattern set during the ATPG run, and saves the patterns to a pattern file with the name *patfile*:

```
add_write_controls 0 w1
set_system_mode analysis
add_faults -all
create_initialization_patterns p1.ram/u1
create_patterns
write_patterns patfile
```

Related Topics

[read_modelfile](#)

[write_modelfile](#)

create_instance

Context: all contexts

Mode: insertion

Instantiates an instance of a module `mod_spec` inside a design module in the current design.

Usage

```
create_instance hierInstPath -of_module mod_spec  
    [-below_instance instance_object]  
    [-allow_instance_uniquification [-instance_uniquification_suffix string]]  
    [-parameter_values parameter_list]  
    [-silent]
```

Description

If the command is successful, this command returns a collection containing the newly created instance.

The pathname to the location must exist in the design up to the leaf level. If the leaf level already exists and the `-allow_instance_uniquification` switch is specified, Tessent Shell adds a uniquification suffix to the new instance to create a unique instance name. The uniquification suffix defaults to `_#` where `#` is replaced by the first available integer starting from 1. You can specify a different uniquification suffix using the `-instance_uniquification_suffix` option in the `create_instance` command or in the [set_insertion_options](#) command.

In addition, ports of the module that have the [function](#) attribute set to “tie0” or “tie1” are automatically tied on the created instance.

Arguments

- ***hierInstPath***

A required string that specifies the hierarchical path in which the instance is to be created concatenated to the leaf instance name of the new instance. The specified hierarchical path in which the instance is to be created must exist in the design. If an instance of the module to be instantiated already exists in that module, by default the tool uniquifies the new name by adding a “_#” suffix to the instance name. You can use the `instance_uniquification_suffix` switch to specify a different suffix.

- **`-of_module mod_spec`**

A required switch and value pair that specifies the module to be instantiated. `mod_spec` can be the name of a module or a module object returned by the [get_modules](#) command.

Note

Currently, any instantiation of parameterized modules can only be done with default values.

- `-below_instance` *instance_object*

An optional switch and value pair that specifies to create the instance below the specified *instance_object*. The instance specified with the ***hierInstPath*** value is created below the specified instance using the `-below_instance` switch. Using this switch enables you to create instances below a given instance without having to extract the name of that instance and use it as the beginning part of the ***hierInstPath*** value with a “/” to separate the two parts.

Note

If the *instance_object* is an empty collection or an empty string, the `create_instance` command uses the current design as the parent instance.

- `-allow_instance_uniquification`

An optional switch that specifies to automatically uniquify the name of the new instance being instantiated if an instance of the same name already exists in the current design. This feature is very useful when inserting gates to intercept signals. You can always use the same leaf instance name and let the tool resolve conflicts automatically. This use model is illustrated in Examples 2, 3, 4 and 5 in the [move_connections](#) command description.

- `-instance_uniquification_suffix` *string*

An optional switch that specifies a string to add to the new instance name when an instance of the same name already exists and you specify the `-allow_instance_uniquification` switch. If you don't specify this switch, the tool automatically uniquifies the object using the default string “_#” where # begins at 1 and increments by one until a unique name has been found. The string must always end with a # to denote the uniquification integer. You can also specify a different uniquification suffix using the [set_insertion_options](#) command.

- `-parameter_values` *parameter_list*

An optional switch that specifies a Tcl list of parameter values when you use the command to create an instance of a parameterized module. The instance uses the supplied list of parameter values. For an example of how to use this switch, refer to “[Example 4](#)” on page 563.

This switch is available only in `-rtl` mode (“`set_context dft -rtl`”). For more information, refer to the [set_context](#) command.

- `-silent`

An optional argument that specifies to not generate an error message under the following condition. When the error is suppressed, no instance is created and the command returns a null collection. When no errors are suppressed, the command returns a collection containing the newly created instance.

- The hierarchical path above the leaf instance name does not exist in the design.
- The specified `mod_spec` is not the name of an existing module.
- The collection supplied to the `-of_module` option does not contain a single module object.

Examples

Example 1

The following example creates an instance of module ModA called ModA_1 inside instance Block1_I1/Block2_I1. The return value is an instance object by the name of Block1_I1/Block2_I1/ModA_1.

```
create_instance Block1_I1/Block2_I1/ModA_1 -of_module ModA  
{Block1_I1/Block2_I1/ModA_1}
```

Example 2

The following example creates two instances of module MUX called MUX inside instance Block1_I1. The tool uniquifies the leaf instance name when a name conflict occurs on the second invocation of the command.

```
create_instance Block1_I1/MUX -of_module MUX -allow_instance_uniquification  
{Block1_I1/MUX}  
  
create_instance Block1_I1/MUX -of_module MUX -allow_instance_uniquification  
{Block1_I1/MUX_1 }
```

Example 3

This example creates two instances of module MUX called MUX inside instance Block1_I1. The tool uniquifies the leaf instance name when a name conflict occurs. The `get_attribute_value_list` command returns the value of the `leaf_name` attribute on the new instance name.

```
get_attribute_value [create_instance Block1_I1/MUX -of_module MUX \  
-allow_instance_uniquification] -name leaf_name  
{MUX}  
  
get_attribute_value [create_instance Block1_I1/MUX -of_module MUX \  
-allow_instance_uniquification] -name leaf_name  
{MUX_1}
```

Example 4

This example creates an instance of a parameterized module using a list of parameter values. This example is based on the following Verilog module:

```
module ff (clk,d,q);  
    parameter SIZE = 1;  
    parameter OTHER = 0;  
    input      clk;  
    input  [(SIZE-1):0] d;  
    output [(SIZE-1):0] q;  
    reg      [(SIZE-1):0] q;  
    ...  
}
```

create_instance

- The following command

```
create_instance ff_i3 -of_module ff -parameter_values { SIZE 10 }
```

creates the following Verilog code:

```
ff #(.SIZE(10), .OTHER(0)) ff_i3(.clk(), .d(), .q());
```

- The following command

```
create_instance ff_i4 -of_module ff -parameter_values [list SIZE 10 OTHER 8]
```

creates the following Verilog code:

```
ff #(.SIZE(10), .OTHER(8)) ff_i4(.clk(), .d(), .q());
```

- The following command

```
create_instance ff_i5 -of_module ff -parameter_values {SIZE {"file1.txt"} OTHER 0}
```

creates the following Verilog code:

```
ff #(.SIZE("file1.txt"), .OTHER(0)) ff_i5(.clk(), .d(), .q());
```

Example 5

To see how to pass a parameter that is defined in a Verilog module to another parameter, consider this module declaration in *top.v*:

```
module top(input1);
input input1;
parameter my_param = 8;
endmodule
```

The following command

```
create_instance core_inst -of_module top -parameter_values {SIZE my_param}
```

instantiates the core in *top.v*:

```
module top(input1);
input input1;
parameter my_param = 8;
  core #(.SIZE(my_param), .OTHER(2)) core_inst( .input1());
endmodule
```

create_layout

Context: patterns -scan_diagnosis

Mode: analysis

Generates a diagnosis tool-compatible Layout Database directory (LDB) from LEF/DEF input files.

Usage

```
create_layout layout_database_name [ -lef lef_filename ... | -leflist leflist ]  
  [-def def_filename ... | -deflist deflist ]  
  {[ -extra_layout_hierarchy extra_levels_of_hierarchy_in_layout ] | [ -extra_design_hierarchy  
  extra_levels_of_hierarchy_in_design ]}  
  [-threshold percentage_match ] [-topology_threshold percentage_match ]  
  [-temp_dir directory_name ] [-compression {on | off} ]  
  [-keep_uncompressed_database] [-core core_name ] [-verify_only]  
  [-threads num_threads ] [-min_threads min_threads ]  
  [-compact {on | off} ] [-bridge_proximity_factor bridge_proximity_factor ]  
  [-topology_error_count integer ]  
  [-gray_box_detection]  
  [-hierdb hierdb_name ] [-replace] [-continue] [-upgrade]
```

For Pre-Existing LDBs

```
create_layout layout_database_name [-adjust_vias ]
```

Description

Refer to “[Layout-Aware Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

Before generating the LDB, the tool performs layout verification of the LEF/DEF files and reports any mismatches to the transcript—refer to “[Layout Verification and Layout Database Creation Process](#)” in the *Tessent Diagnosis User’s Manual*.

After the layout-verification stage, you can interrupt the LDB creation by issuing a Ctrl-C in the invocation shell. You can subsequently use the [report_layout_rules](#) command to obtain details on the layout rule violations and use this information to correct errors in LEF/DEF files, providing the correct LEF/DEF files and add any missing LEF/DEF files to the list provided to the `create_layout` command. Following this, you then use the `create_layout` command to determine if there are any additional issues. Use this method in iterative fashion to correct any problems with the LEF/DEF before creating the LDB.

After generating the LDB, the tool performs layout pre-extraction. The tool extracts bridge and open defect information and stores this information in the LDB for use with RCD constant creation (with the [create_feature_statistics](#) command) and dynamic partitioning-based diagnosis. In addition, layout pre-extraction improves layout-aware diagnosis performance.

You can improve runtime performance of the layout pre-extraction step by specifying the `-threads` and `-min_threads` options. These options enables you to check out additional licenses so that Tessent Diagnosis can perform some layout pre-extraction tasks in parallel.

Tip

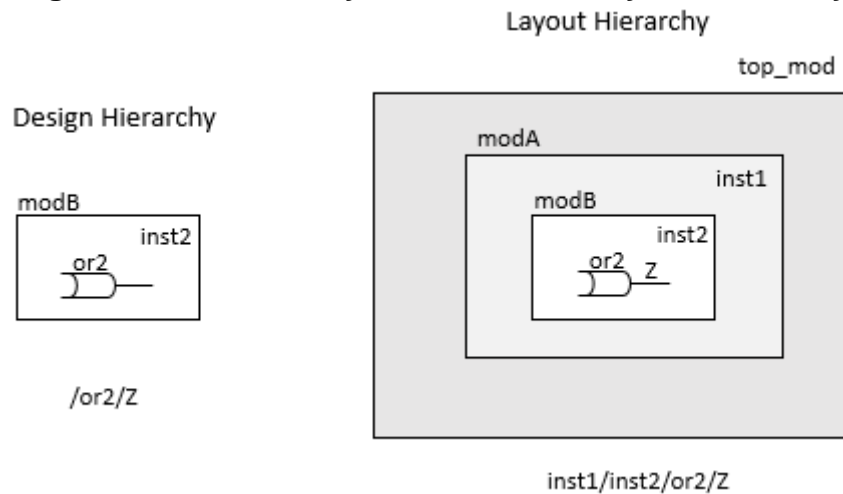

i For maximum efficiency, run the `create_layout` command on a disk that is local to the machine hosting the process. Also, because this command reads the entire physical layout information into memory by default, you should run it on a machine with sufficient physical memory.

Arguments

- ***layout_database_name***
A required string that specifies the name of the LDB that diagnosis creates from the LEF/DEF input.
- ***-lef lef_filename ...***
An optional switch and string that specifies space-separated name(s) of the LEF file(s).
- ***-leflist leflist***
An optional switch and string pair that specifies a Tcl list of the LEF file(s).
- ***-def def_filename ...***
An optional switch and string that specifies space-separated name(s) of the DEF file(s).
- ***-deflist deflist***
An optional switch and string pair that specifies a Tcl list of the DEF file(s).
- ***-extra_layout_hierarchy extra_levels_of_hierarchy_in_layout***
An optional switch and string pair that removes extra levels of layout hierarchy in the LEF/DEF layout such that the design hierarchy and layout hierarchy match. You can only specify this switch once, otherwise the tool issues an error and exits.

Use this switch if a core instance is a subset of a larger layout hierarchy. You can specify multiple levels of hierarchy in one string with no spaces. The following figure illustrates this usage.

Figure 3-28. create_layout With Extra Layout Hierarchy

The following command removes the hierarchy from the LEF/DEF net, pin names, and so forth before matching with the design name:

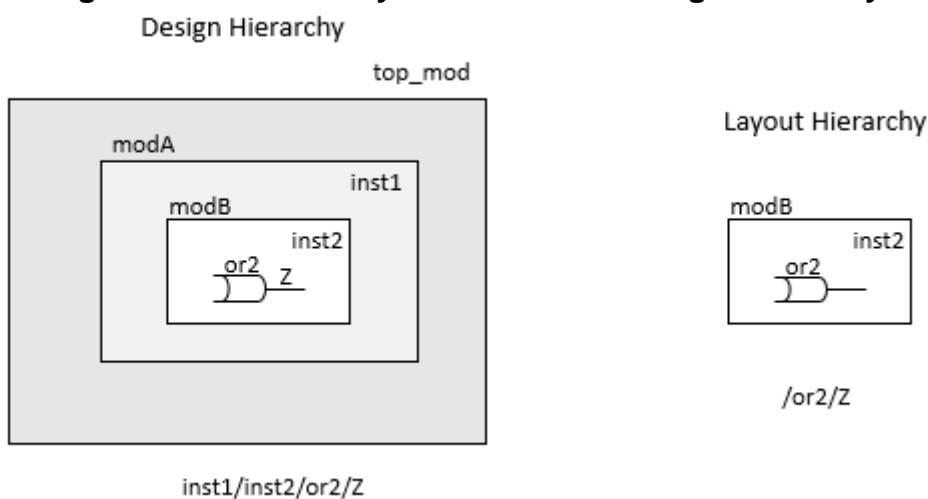

```
create_layout layout_database_name -lef lef_file -def def_file \
    -extra_layout_hierarchy inst1/inst2
```

- `-extra_design_hierarchy extra_levels_of_hierarchy_in_design`

An optional switch and string pair removes extra levels of design hierarchy such that it matches the LEF/DEF layout hierarchy. You can only specify this switch once, otherwise the tool issues an error and exits.

You use this switch if a core instance is a subset of a larger design hierarchy. You can specify multiple levels of hierarchy in one string with no spaces. The following figure illustrates this usage.

Figure 3-29. create_layout With Extra Design Hierarchy

The following command removes hierarchy from a design pin, net name, and so forth before matching with layout:

```
create_layout layout_database_name -lef lef_file -def def_file \  
-extra_design_hierarchy inst1/inst2
```

Note

 The `-EXTRA_DESign_hierarchy` and `-EXTRA_LAYout_hierarchy` switches are mutually exclusive, and the tool issues an error if you specify both.

- `-threshold percentage_match`

An optional switch and integer pair that specifies the minimum percentage match threshold required to successfully complete a layout verification of the LEF/DEF files, and subsequent creation of the LDB. The default threshold value is 85 percent. The following command sets the required layout match threshold to 92 percent:

```
create_layout design.layout -lef lef_input.lef -def def_input.def \  
-threshold 92
```

- `-topology_threshold percentage_match`

An optional switch and integer pair that specifies the minimum percentage net tracing threshold required to successfully complete topology extraction during the LDB creation process. The default threshold value is 90 percent, meaning topology extraction is considered successful if the tool can trace 90 percent of the nets. If the success rate falls below the default or user-specified *percentage_match* rate, the tool issues an error and stops LDB creation.

- `-temp_dir directory_name`

In some cases, Tessent Diagnosis must update the LDB (for example, if you use the `-verify` switch). Due to the fact that the compressed LDB is a read-only database, Tessent Diagnosis automatically uncompresses, updates, and re-compresses the LDB. By default, the temporary uncompressed LADB is stored into the same location where the compressed LDB is located; if you have limited disk space in this location, then use the `-TEmp_dir` switch and string pair to specify an alternative location.

Refer to “[Layout Database Compression and Decompression](#)” in the *Tessent Diagnosis User's Manual* for complete information.

- `-compression {on | off}`

An optional switch and literal that controls whether the tool compresses the LDB during database creation. The default is OFF. Specify ON to create a compressed LDB.

Refer to “[Layout Database Compression and Decompression](#)” in the *Tessent Diagnosis User's Manual* for complete information.

- `-keep_uncompressed_database`

An optional switch that specifies that the tool retain a copy of the uncompressed LDB as well as a compressed version of the LDB.

- `-core core_name`

An optional switch that specifies to create an instance-aware core-level LDB for the specified core design. This option only pertains to and is required for the hierarchical layout-aware diagnosis flow.

Refer to “[Diagnosis for Hierarchical Design](#)” in the *Tessent Diagnosis User's Manual* for complete information.

- `-verify_only`

An optional switch that enables LEF/DEF design verification and stops LDB creation after verification steps have completed.

- `-threads num_threads`

An optional switch and integer pair that specifies the number of CPUs to use so that the tool can run some `create_layout` tasks in parallel.

num_threads is an integer such that:

num_threads > 1: Use the specified number of threads.

num_threads = 0: Use the number of CPUs of the host for the number of threads.

num_threads < 1: Use the number of CPUs less the specified *num_threads* value.

If the requested number of threads is greater than the host's CPUs, the tool automatically adjusts the thread count down to the number of CPUs.

The tool requires one `yieldascandiag` license per thread. For example, if you specify “`-threads 8`”, the tool checks out 7 `yieldascandiag` licenses in addition to the 1 `yieldascandiag` license that was checked out when you entered `scan_diagnosis` context. The tool releases the additional licenses when the `create_layout` command completes processing.

If less than the requested licenses are available, license queuing occurs based on the setting from the `set_license_queue_timeout` command. If the tool cannot acquire the number of licenses specified by the user, the number of threads is adjusted down to the number of acquired licenses.

- `-min_threads min_threads`

An optional switch and integer pair that is used with the `-threads` option and specifies the minimum number of threads that must be available. The tool aborts the `create_layout` command if the number of acquired licenses does not meet the `-min_threads` requirement.

num_threads is an integer such that:

num_threads > 1: Use the specified number of threads.

num_threads = 0: Use the number of CPUs of the host for the number of threads.

num_threads < 1: Use the number of CPUs less the specified *num_threads* value.

- `-compact {on | off}`

An optional switch that specifies whether to produce a compact LDB, which is an optimized database that is faster to create and has a smaller size on disk. Compact LDBs have the following limitations:

- In the Tessent YieldInsight layout viewer, you do not see background polygons. (Landmark and suspect polygon display remains the same.)
- The tool does not perform DFM rule verification during the `import_dfm` process. (The rest of the DFM flow and reporting remains the same.)

You can convert existing compact LDBs by specifying “`create_layout existing_LDB -compact off.`”

- `-bridge_proximity_factor bridge_proximity_factor`

An optional switch that controls the maximum distance permitted between nets for them to be considered possible bridge defects. Specify a scale factor from 1 to 100. The default is 10. The tool calculates the maximum distance by multiplying the specified scale factor by the minimum net spacing between the layer.

This option is useful for eliminating bridge suspects that have minimal significance for failure analysis thus improving resolution metrics.

- `-topology_error_count integer`

An optional switch and integer that specifies the number of net errors per issue class to display in the net topology extraction transcript. The default is 5.

- `-gray_box_detection`

An optional switch that specifies to populate the LDB with graybox layout information for the purposes of performing graybox-aware top-level pattern diagnosis. For more information, refer to “[Top-Level Layout-Aware Diagnosis](#)” in the *Tessent Diagnosis User’s Manual*.

- `-hierdb hierdb_name`

An optional switch that specifies the name of a layout hierarchy database as created by the [analyze_layout_hierarchy](#) command. When you specify this option, the tool implements the optimized chip-mapped core-level LDB creation process as described in “[Generating Chip-Mapped Core-Level LDBs](#)” in the *Tessent Diagnosis User’s Manual*. This process optimizes core-level LDB creation by only processing the DEFs required for a specified core.

- `-replace`

An optional switch that overwrites existing layout pre-extraction information stored in the LDB with newly generated layout pre-extraction files.

create_layout

- -continue

An optional switch that specifies to continue generating the LDB, including the layout open and bridge defect information. Use this switch when:

- Processing halts for any reason. The tool automatically re-starts processing where it left off.
- You have a pre-2014.4 LDB and you would like to add layout open and bridge defect information to it.

- -adjust_vias

An optional switch that merges vias with the same physical geometries and layer names under one name, and adjusts the LDB accordingly. This results in consistent via naming, which can improve the accuracy of RCD results. The tool does not perform verification, pre-extraction, or LDB re-creation. Refer to Example 6.

To receive the benefit to RCD accuracy from via merging, you must re-create existing diagnosis reports by re-running diagnosis with the updated LDB. The feature statistics (`create_feature_statistics`) do not need to be recalculated.

- -upgrade

An optional switch that analyzes and performs any required upgrades to the specified LDB. If upgrades are not required, no changes will be made to the LDB.

Examples

Example 1

In the following example, the diagnosis tool creates a LDB (*design.layout*) directory that includes pre-extracted bridge and open information from multiple LEF files and DEF files:

```
create_layout design.layout -lef lef_input01.lef lef_input02.lef -def def_01.def def_02.def
```

Example 2

In the following example, Tessent Diagnosis creates a LDB (*design.layout*) directory that includes pre-extracted bridge and open information from a LEF file (*lef_input.lef*) and four DEF files (*a.def*, *b.def*, *c.def*, *d.def*). It skips re-generating valid pre-extraction information.

```
create_layout design.layout -lef lef_input.lef -def a.def b.def c.def d.def -continue
```

Example 3

In the following example, the tool pre-extracts layout bridge and open defect information and stores it in an existing LDB. It recreates all the layout pre-extraction information.

```
create_layout design.layout -replace
```

Example 4

In the following example, the `set_license_queue_timeout` is set for a one minute timeout and you have specified to check out four licenses (for four threads) with the `create_layout` command.

set_license_queue_timeout 1**create_layout results/layoutDB -def ya_demo6.def.gz -lef ya_demo5.lef.gz -threads 4**

```
// Note: multithreading license queue type: timeout wait
// Note: Requested threads (4) requires check out of 3 additional
// licenses.
// Note: Acquired 2 of 3 requested licenses.
// Note: Queueing 1 minute for 1 license ( CTRL-C to run with available
// licenses ).
// Waited 1 of 1 minute for 'yieldascandiag'.
// Warning: Could not acquire 3 licenses. Proceeding with reduced thread
// count of 2.
```

Example 5

In the following example, the `set_license_queue_timeout` is set for no waiting and you have specified that you require four licenses. However, there are only three available licenses.

set_license_queue_timeout no_queue**create_layout results/layoutDB5 -def ya_demo6.def.gz -lef ya_demo5.lef.gz -threads \
4 -min_threads 4**

```
// Note: multithreading license queue type: no_queue
// Note: Requested threads (4) requires check out of 3 additional
// licenses.
// Note: Acquired 2 of 3 requested licenses.
// Error: Insufficient licenses acquired (2) and -min_threads (4)
// specified.
// Note: Releasing 2 licenses.
// Error: Layout feature preparation failed.
```

Example 6

The following example shows how Tessent Diagnosis merges vias with the same physical geometries and layer names when you specify `create_layout -adjust_vias`.

The tool begins the analysis by grouping LEF and DEF vias that have the same physical geometries and layer names. Within a group of equivalent vias, the tool arrives at the merged via name as follows:

1. Consider LEF via names first. If there is only one LEF via in the group, use its name.
For example:

```
abcasc      // LEF via ---> use this name
xyyx       // DEF via
abc        // DEF via
```

2. If there are multiple LEF vias, use the LEF via with the shortest via name. For example:

```
abcasc      // LEF via
streq      // LEF via ---> use this name
xyyx       // DEF via
abc        // DEF via
```

create_layout

3. If there are multiple LEF vias and two (or more) have via names of the same shortest length, use the name with the lowest alphanumeric value. For example:

```
abcas  // LEF via
xyyx   // LEF via
abcd   // LEF via ---> use this name
abc    // DEF via
```

4. If there are no LEF vias, use the DEF via with the shortest via name.
5. If there are two (or more) DEF vias of the same shortest length, use the name with the lowest alphanumeric value.

create_module

Context: all contexts

Mode: insertion

Creates a new design module with no ports.

Usage

```
create_module module_name [-language {verilog | vhdl}] [-in_library library_name]  
    [-vhdl_architecture vhdl_architecture] [-silent]
```

Description

The `create_module` command returns a collection of one module object where the module is a newly created module.

After creating a module with this command, you can set the new module as the top level of the design for all subsequent commands by using the [set_current_design](#) command and providing the name of the new module.

You can add ports to this new design module using the [create_port](#) command, add instances using the [create_instance](#) command, and then connect the pins using the [create_connections](#) command. Optionally, you can save the completed module to disk using the [write_design](#) command. Refer to “[Design Editing Examples](#)” section of the *Tessent Shell User's Manual*.

After a new module is created, the current design can be reset to a different level with the `set_current_design` command and the module can be inserted with a `create_instance` command.

Arguments

- ***module_name***
A required string that specifies the name of the module to create.
- `-language verilog | vhdl`
An optional switch and literal pair that specifies which language (Verilog or VHDL) to use when creating the module. The language defaults to Verilog when this option is not specified. The `-language` option is only permitted in the rtl context.
- `-in_library library_name`
An optional switch and string pair that specifies in which library to create the module. The specified `library_name` must be a library name previously defined with the [set_logical_design_libraries](#) command. When the `-in_library` option is not specified, the module is created inside the default library, which is also specified using the `set_logical_design_libraries` command. The `-in_library` option is only permitted in the rtl context.

create_module

- `-vhdl_architecture vhdl_architecture`

An optional switch and string pair that specifies the name of the architecture to use for a created VHDL module. When `-vhdl_architecture` is not specified and `-language` is specified as `vhdl`, the created architecture is called `struct`. You cannot specify `-vhdl_architecture` unless `-language` is specified as `vhdl`. The `-vhdl_architecture` option is only permitted in the `rtl` context.

- `-silent`

An optional switch that suppresses the error that is normally generated if `module_name` already exists. A null collection is returned when an error is suppressed.

Examples

Example 1

The following example creates a module called `mytop` and makes it the current module so that other modules can be instantiated in it.

```
set_context dft -no_rtl
set_system_mode insertion
create_module mytop

{mytop}

set_current_design mytop
```

Example 2

The following example creates a module called `myblock` and appends the newly created module object to a collection referenced by the Tcl variable called `created_modules`.

```
append_to_collection created_modules [create_module myblock]

{myblock}
```

Example 3

The following example creates a VHDL module inside library `lib1` with the default `vhdl` architecture `struct`. Note how the [get_modules](#) command is used to report its attribute as `report_attribute` only looks for modules in the default library

```
create_module M1 -in_library lib1 -language vhdl

{M1}

report_attributes [get_modules M1 -in_library lib1]

Attribute Definition Report
```

```

Attributes defined for object 'M1':

- [create_port](#)
- [get_modules](#)

create_net

Context: all contexts

Mode: insertion

Creates a net inside an instance of a design module in the current design.

Usage

```
create_net hier_net_name  
    [-below_instance instance_object]  
    [-ascending]  
    [-silent]
```

Description

This command returns a collection of created net objects. This command returns one object for each bit of a bus with the left bit first and the right bit last.

Arguments

- ***hier_net_name***
A required string that specifies the path to the instance in which the net is created, and the leaf name of the net to be created in the module. If the net name is a bus, this command creates one net for each bus bit, beginning with the left-most bit of the bus and ending with the right-most. The specified hierarchical path in which the net is to be created must exist in the design.
- **-below_instance *instance_object***
An optional switch and value pair that specifies to create the net below the specified *instance_object*. The tool searches the specified *name_patterns* relative to each instance found in the *instance_object* list. If the *instance_object* is a null collection or a null string, the switch is ignored and instances are searched relative to the current design.
- **-ascending**
An optional switch that specifies the range direction type for a VHDL bus port. By default, the range direction type is inferred as “downto” when the left index is larger than the right index, and as “to” when the left index is smaller than the right index. You use this switch to specify that the VHDL port notation is “to” when the left index is equal to the right index; otherwise, the tool uses the “downto” range direction type. An error is generated if you specify this option and the left index is larger than the right index, or if the object name is not a bus. The -ascending option is only permitted in the rtl context.
- **-silent**
An optional argument that specifies the suppression of an error given one of the situations below. The command returns a null collection when an error is suppressed.
 - The hierarchical path of the net name specified does not exist in the design

- The net already exist in the design

Examples

The following example creates a two-bit bus net called A inside instance u1.

```
create_net u1/A[4:5]  
{u1/A[4] u1/A[5]}
```

create_open_socket_failure

Context: patterns -failure_mapping

Mode: setup

Creates emulated open-socket failure files to use for validating reverse mapping top-level failures to the core in Tessent Diagnosis.

Usage

create_open_socket_failure *failure_filename* [-pattern_count *count*] [-replace]

Description

An open-socket failure log is a file that would be created if the test was run without a chip in the socket. When you specify this command, the tool loops over the patterns and cores in the design to find the scan chains and top-level pins. A fail bit is output on each top-level pin for each chip-level measure cycle that is not filtered by -pattern_count.

For usage details, see “[Validating Reverse Mapping Prior to Core-Level Layout-Aware Diagnosis](#)” in the *Tessent Diagnosis User’s Manual*.

Note

This command does not work with SSN. If you run this command in a design with SSN present, the tool reports the following error:

```
// Error: This command is currently not supported in the presence of SSN.
```

Arguments

- **failure_filename**
A required string that specifies the name of the output open-socket failure file.
- **-pattern_count *count***
An optional switch and integer that specifies the number of patterns to output from the beginning and end of each test suite. If the count is zero, then the entire pattern range is output. The default is one, which leads to failures being generated for the first and last pattern of each test suite.
- **-replace**
An optional switch that overwrites existing open-socket failure information with newly generated data.

create_patterns

Context: dft -edt, patterns -scan

Mode: analysis

Performs automatic high-speed test generation and pattern compression.

Usage

```
create_patterns [-OvErriDe_user_settings | -NO_AUto]
  [-COmpaction_effort {Low | High | Maximum | integer}] [-NO_Analyze]
  [-COvErage_effort {Low | High}] [-NO_REdundancy_analysis]
  [-NO_TERMINATE_ineffective_atpg] [-PATterns_per_pass integer]
  [-NO_REPort_statistics]
```

Description

This command is the recommended way to produce high quality, efficient, test pattern sets in the shortest possible time.

This is a multiprocessing command for ATPG. For more information about multiprocessing, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User’s Manual*.

The create_patterns command uses the built-in expert system, ATPG Expert, to create patterns. ATPG Expert analyzes the design and DRC and may modify tool settings to optimize test patterns for coverage, pattern count, and run time. By default, ATPG Expert only optimizes settings that have not been explicitly specified; it does not change user-specified settings. If you want ATPG Expert to also optimize user-specified settings, use the -override_user_settings switch. Additionally, a statistics report is automatically displayed. The create_patterns command displays the following statistics:

- Number of patterns simulated
- Test coverage
- Number of faults detected
- Number of faults remaining in the fault list (undetected)
- Number of effective patterns
- Number of test patterns
- Number of redundant, untestable, and aborted faults

Occasionally, the display includes a line with three or four numbers separated by slashes (/). These numbers are, from left to right, the cumulative number of redundant (RE), ATPG_untestable (AU), and aborted faults. Aborted faults are separated into ATPG aborts (AAB) and EDT aborts (EAB) depending on whether compression is on. The sum of AAB and EAB aborts equal the total number of aborts.

Example transcript without compression (these numbers are shown in bold font):

```
//#patterns test      #faults #faults  #eff.  #test  process  RE/AU/AAB
//simulated coverage in list detected patterns patterns CPU time
//  ---      ---      ---      ---      ---      ---      5.79 sec  0/40868/57

//      64      74.10%  135463  413980      63      63      14.73 sec
```

Example transcript with compression (these numbers are shown in bold font):

```
//#patterns test      #faults #faults  #eff.  #test  process  RE/AU/AAB/EAB
//simulated coverage in list detected patterns patterns CPU time
//  ---      -----      ---      ---      ---      ---      5.79 sec  0/40868/27/30
//      64      74.10%  135463  413980      63      63      14.73 sec
```

Note

 At the start of create_patterns, when the hardware has EDT and the EDT low-power controller is enabled, but [set_power_control](#) has not been used, the tool issues the following note. The note says “highest” because there may be multiple active EDT instances, and they may have different hardware thresholds.

```
// Note: Creating low-power patterns with <N>%
// shift switching threshold based on highest threshold of all active EDT
// low-power controllers or 15%, whichever is higher.
// To use a different low power shift threshold or disable low
// power shift, use the 'set_power_control shift on
// -switching_threshold_percentage <int>' command.
```

At the end of the create_patterns run, the tool automatically performs redundant fault identification, which is equivalent to running the [identify_redundant_faults](#) command. If, however, you set any ATPG limit (for example, test coverage limit, run time limit, or pattern limit), then the tool does not perform redundant fault identification.

You should use the create_patterns command, review the transcript for any suggested command or setting changes, and implement the ones that help you achieve your test goals. Be aware that some of the suggestions have trade-offs (for example, greater run time in exchange for fewer test patterns); the merits of the trade-offs depend on your particular test requirements.

Note

 When you perform compression analysis, the final order of scan cells in each scan chain in the design is not known. The order of the scan cells used as deterministic bits in the test cube impacts ATPG results. If many of the deterministic bits are clustered in consecutive cycles, more EDT_ABORT faults may appear because the clustered deterministic bits may not be compressed. When this occurs, ATPG test coverage may drop.

During compression analysis, the tool assumes the scan chains are organized in a balanced way based on an existing scan cell ordering. However, in the real design, scan cells may be in an arbitrary position depending on which scan stitching tool was used. If the clustering of deterministic bits occurs during compression analysis but not in the real design or if the

clustering occurs in the real design but not in compression analysis, a discrepancy in the ATPG results may occur.

For static fault models, the tool automatically calls “add_faults -all” when the create_patterns command is run and the fault list is empty.

For transition and UDFM with defect_delay fault models, the tool automatically calls “add_faults -clock_domains all” when the create_patterns command is run and the fault list is empty. The tool does this to ensure that at-speed test is only performed within groups of synchronous clocks.

Note that you can use the [add_faults](#) command to define the scope of the create_patterns command. For more information, refer to “[Example 3](#)” on page 586.

The CPU time the tool reports is the time local to the command. If the command has multiple phases, then the reported CPU time is with respect to the beginning of that phase.

Arguments

- -OVERRIDE_user_settings

An optional switch that enables ATPG Expert to override user-specified settings if necessary to create an optimal test pattern set.

- -NO_Auto

An optional switch that turns off use of ATPG Expert to create patterns. During test generation, the default settings are used for those settings that have not been explicitly specified.

- -Compaction_effort {Low | High | Maximum | *integer*}

An optional switch that specifies how much effort to spend trying to reduce the pattern count:

Low

Specifies a faster run time but a higher pattern count than the High option.

High

Specifies a longer run time but a smaller pattern count than the Low option. Use High when generating production patterns because this can significantly reduce test time and test data volume. This option usually gives the best results and is the default.

Maximum

Enables maximum tool effort to reduce pattern count. This option significantly increases run time and should be used only when absolutely necessary. Integer value 10 or 100 should be used before using this option due to the significantly long run time.

integer

A positive integer value that specifies compaction effort as follows:

0 = Low

1 = High (usually give the best results)

n = The tool works n times harder than High

As a general guide, when $n=10$, the run time increase is small, and the pattern count can be slightly better. When $n=100$, pattern reduction can be similar to Maximum, while the run time can be lower than Maximum. Differences in design complexity and size can affect which integer value provides the trade-off between pattern counts and run time you want.

Note that you can significantly reduce the run time caused by higher integer values by using multiprocessing. For more information about multiprocessing, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **-NO_Analyze**

An optional switch that skips the analysis of test generation problems. Normally, before test generation, create_patterns checks for bus contention and whether ATPG restrictions and constraints can be satisfied. If these checks reveal potential test generation problems, an error message displays and the command terminates. If you want the analysis to be ignored and to proceed with test generation, reissue the command with this switch.

Note

 Because this switch prevents normal analysis, all faults can be targeted, and ATPG effort expanded, yet without generating patterns. The extra effort may also give the appearance that the tool is stuck. Use this switch only in special cases when the risks are acceptable.

- **-COverage_effort {Low | High}**

An optional switch that improves ATPG test coverage. When set to High, the tool retargets aborted faults and uses dynamic learning during retargeting. Note that using this setting can result in significantly higher run times in some cases. By default, the tool does not retarget aborted faults.

Using this switch may increase the ATPG run time.

- **-NO_REDundancy_analysis**

An optional switch that omits the redundancy identification analysis that follows pattern generation. When you use this switch, the patterns generate faster, but the test coverage calculations are less accurate.

- **-NO_TERMINATE_ineffective_atpg**

An optional switch that turns off a feature that terminates the ATPG session after the patterns are no longer efficient at detecting faults. Note that using this switch results in a longer run time and may generate many additional patterns to detect very few faults.

- `-PATterns_per_pass` *integer*

An optional switch and positive integer pair that specifies how many patterns to create and simulate in each pass. The integer value must be between 1 and 64. By default, the tool creates and simulates 64 patterns in each pass. When the value is 1, the tool generates and simulates every pattern, and so on. The switch affects only the current `create_patterns` session.

The potential benefit of using a smaller integer value rather than the default 64 is better pattern count because ATPG is less likely to add non-essential faults into a pattern. However, when the value is small, the overall run time is likely to increase due to excessive fault simulation. Furthermore, a small value can reduce the run-time efficiency of multithreading and distributed ATPG.

A smaller value is appropriate if the expected pattern count is small. A typical scenario for using a small integer value is IDDQ pattern generation, where you should use “`create_patterns -patterns_per_pass 1`” with “`set_atpg_limits -pattern_count n`” for creating *n* IDDQ patterns. You can use the `-compaction_effort` option with `-patterns_per_pass` to maximize the effectiveness of each pattern, but at the expense of additional run time.

- `-NO_REPort_statistics`

An optional switch that suppresses statistics reporting after the tool creates patterns. This is helpful for avoiding duplicate reports when you want to run the [report_statistics](#) command with non-default options immediately after running `create_patterns`.

Examples

Example 1

The following example creates, through ATPG Expert, an internally-stored set of optimally compact patterns for the entire netlist that can be saved using the `write_patterns` command. ATPG Expert automatically decides the best setup (for example, sequential depth) for the design.

```
set_system_mode analysis  
create_patterns
```

Example 2

The following example also creates an internally-stored set of compact patterns; however, ATPG Expert has been turned off. In this case, you must specify which sequential depth the pattern is created. The `-sequential 2` switch means there are up to two clock pulses between scan loads. The patterns can be saved using the `write_patterns` command.

```
set_system_mode analysis  
set_pattern_type -sequential 2  
create_patterns -no_auto
```

Example 3

The following example creates patterns only for the specific block specified by the `add_faults` command:

```
set_system_mode analysis
add_faults /blockA/blockB
create_patterns
```

Example 4

The following example creates, through ATPG Expert, an internally-stored set of optimally compact at-speed fault patterns for the entire netlist that can be saved using the `write_patterns` command. Notice that for at-speed fault models, if you are not using named capture procedures, and there are no user defined settings or you are not calling `create_patterns` with the `-override` switch, the tool automatically turns on `hold_pi` and mask all primary outputs. It also automatically sets clock restriction to "domain_clock" with `any_interaction` and `compatible_clocks_between_loads ON`.

```
set_system_mode analysis
set_fault_type transition
rep_faults
```

```
// Warning: No faults reported.
```

create_patterns

```

create_patterns_specification

Context: All context

Modes: All modes

Prerequisite: The top level ICL module must exist and be elaborated.

Generates a pattern specification for the specified usage. The usage is either signoff or manufacturing. The tool supports IJTAG and MemoryBIST patterns.

Usage

```
create_patterns_specification [usage] [-replace] [-ignore ignored_instrument_list]
    [-bsdl_files bsd_file] [-infer_loopbacks_during_icl_verify { on | off } ]
```

Description

This command can be called in any context and any system mode as long as the ICL module associated with the top-level design is available and elaborated, or if a BSDL file is specified for a “BSDL-only” design flow. You can provide a top-level ICL module description by using first the [read_icl](#) command followed by the [set_current_design](#) command, or by performing ICL extraction using the [extract_icl](#) command. The context is automatically changed to patterns if called from a different context.

Note

 If you are using SSN and an IJTAG graybox model exists in the TSDB, the `create_patterns_specification` command uses the graybox model instead of the full view.

This command returns the name of the [PatternsSpecification](#) wrapper if it was just created in memory. This makes it easier to modify using the configuration data editing and introspection commands listed in [Table 10-1](#) on page 3647 as shown in the example below.

Note

 The `DftControlSettings` and the [ProcedureStep](#) wrapper are auto filled by the command. Refer to the [Patterns](#) section for a description of where the `DftControlSettings` list comes from. Refer to the documentation of the [tessent_default_procedure_name](#) and [tessent_default_procedure_parameters](#) attributes for a description of their influence on the `ProcedureStep` inference.

There is a special case for the port associated with the 'scan_en' signal where, in addition to this port being added to the [PatternsSpecification/AdvancedOptions/ConstantPortSettings](#), it is also added to the [Patterns/AdvancedOptions/ConstantPortSettings](#) but only for the `JtagBscan` patterns. In this [AdvancedOptions/ConstantPortSettings](#) wrapper, the port is added with the value “-” to have this port not set to a constant value. This way, the boundary scan tests can toggle this port during the tests ensuring proper coverage of the boundary scan cell.

Any port having the attribute 'function' set to 'power' or 'ground' is added to the [AdvancedOptions/ConstantPortSetting](#) wrapper by the [create_dft_specification](#) command but only if that port is not already listed in the 'tessent_power_port_list' or 'tessent_ground_port_list' attribute of the ICL.

Arguments

- *usage*

Specifies the intended usage of the patterns. The permitted values are as follows:

signoff — Indicates that simulation signoff patterns are requested. Signoff patterns are patterns that are used for simulation and verification of the design. They only include a sub-set of patterns by default. With this usage, the ICL file is analyzed to obtain the list of instruments and BIST controllers present in the design. A set of [Patterns](#) wrapper is created per instrument type to fully verify their proper operation inside the design. The properties found inside the [SignOffOptions](#) wrapper are used to configure how the patterns are created. By default, only the instruments and the BIST controllers found in the top physical instance are simulated. You can set the “simulate_instruments_in_lower_physical_instances” property inside the [SignOffOptions](#) wrapper to also request that the instruments and the BIST controllers found in the lower physical instance be re-simulated from the current level. To help with simulation time, those simulation patterns are created so as to have one [Patterns](#) wrapper per instrument type/per lower physical instance that enables the simulation to be done using only the full view of one lower physical instance and an empty view for the rest. Refer to the description of the [LowerPhysicalBlockInstances](#) wrapper found inside the [SimulationOptions](#) wrapper as well as the description of the *design_name.format_interface* file.

In the signoff simulation, the memory BIST controllers (including ROM BIST controllers) are simulated using the [MemoryBist/reduced_address_count](#) property set to On. This assumes that the memory library description has been generated by a certified memory library generator and is correct by construction. If the memory library was created or modified manually, you must simulate the full address space on the memory BIST assembly module, located in the [instruments](#) directory, using the flow mentioned below. Because the top module name ends with “_mbist_assembly”, the [create_patterns_specification](#) command knows to not set the [MemoryBist/reduced_address_count](#) property to “on” so as to simulate the full address space of the memory.

```
> set_context patterns
> read_icl path/design_name_design_id_mbist_assembly.icl
> set_current_design design_name_design_id_mbist_assembly
> create_patterns_specification
> process_patterns_specification
> run_testbench_simulations
> check_testbench_simulations
```

manufacturing — Indicates the manufacturing patterns are requested. Manufacturing patterns are patterns generated for the ATE. They are a complete set of patterns by default. With this usage, the ICL file is analyzed to obtain the list of instruments and BIST controllers present in the design. A set of [Patterns](#) wrappers is created per

instrument type to properly exercise the various test features during manufacturing test. The properties found inside the [ManufacturingOptions](#) wrapper are used to configure how the patterns are created. Based on the `max_async_clock_sources` property value, the patterns are organized to optimize parallelism without exceeding the amount of independent frequency clocks your testcase can supply. Unlike with the original LV flow where you could only have 0 or an unlimited amount of asynchronous clocks, you can know and precisely specify the exact amount of asynchronous clocks available on your tester; the [PatternsSpecification](#) is optimized for that constraint.

- `-replace`

With this option, the error that would normally be generated is ignored when running the command where the [PatternsSpecification](#) wrapper with the same `design_name` and `design_id` and the `pattern_id` already exists in memory. This enables the [PatternsSpecification](#) wrapper present in memory to be replaced with the new one.

- `-ignore ignored_instrument_list`

An optional switch and string list that suppresses generation of the default wrapper for the specified instrument. The only valid instrument for `ignored_instrument_list` is “`ssn`”, which suppresses generation of the default `PatternsSpecification()/Patterns(SSN)/SSNContinuityVerify(default)` wrapper even if SSN is present in the hardware.

- `-bsdl_files bsd_file`

An optional value pair that specifies the BSDL file list to be used in creating the patterns specification for a “BSDL-only” design flow. If this argument is not specified, the BSDL file specified with the `read_icl -bsdl_file` option is used. Refer to the “[BSDL-Only Flow](#)” section of the *Tessent BoundaryScan User’s Manual* for more information.

- `-infer_loopbacks_during_icl_verify { on | off }`

An optional property that turns off the inference of Loadboard loopback pairs. The tool infers these loopbacks when there is a `ScanInterface` of type `Host` in the current design. These loopbacks enable performing verification of the `Host ScanInterface` before connecting to a `Client ScanInterface` at the next level up.

Examples

The following example calls the `create_patterns_specification` command and uses the configuration editing commands to insert in all memory BIST pattern wrappers a `DftControlSetting` wrapper above the first [TestStep](#) wrapper that includes a `DEBUG` macro definition.

create_patterns_specification

```
> set spec [create_patterns_specification]
> set mbist_pats [get_config_el Patterns(MemoryBist_*) -in $spec -silent]
> foreach_in_col mbist_pat $mbist_pats {
>   set first_test_step [get_config_value TestStep<0> -in $mbist_pat -obj]
>   read_config_data -before $first_test_step -from_string {
      SimulationOptions {
        SimulationMacros {
          DEBUG;
        }
      }
    }
}
```

[apply_specification_defaults](#)

[process_patterns_specification](#)

create_pin

Context: all contexts

Mode: insertion

Creates a pin on an instance of a design module.

Usage

```
create_pin hierPinName [-direction input | output | inout] [-ascending] [-silent]
```

Description

If `-auto_uniquify_edited_modules` is On, the module is first uniquified before creating a pin on the specified instance. If `-auto_uniquify_edited_modules` is Off, the pin is created on the module and all instances of the module get the newly created pin.

This command returns a collection of the pin objects created; if `hierPinName` is a bus, this command returns a collection with one pin object for each bus bit, beginning with the left-most bit of the bus and ending with the right-most.

Arguments

- ***hierPinName***
A required string that specifies the hierarchical path of the pin to be created concatenated to the leaf pin name. The specified hierarchical path of the pin to be created must exist in the design.
- `-direction input | output | inout`
An optional switch and literal pair that specifies the direction of the newly created pin. An input pin is created by default when this option is omitted.
- `-ascending`
An optional switch that specifies the range direction type for a VHDL bus port. By default, the range direction type is inferred as “downto” when the left index is larger than the right index, and as “to” when the left index is smaller than the right index. You use this switch to specify that the VHDL port notation is “to” when the left index is equal to the right index; otherwise, the tool uses the “downto” range direction type. An error is generated if you specify this option and the left index is larger than the right index, or if the object name is not a bus. The `-ascending` option is only permitted in the rtl context.
- `-silent`
An optional argument that specifies to not generate an error message if the specified `hierPinName` already exists or when the hierarchical part of the specified name is not an existing instance within the current design. When an error is suppressed, the command returns an empty collection.

Examples

The following example creates a 5-bit bus input pin called A on the instance u1. The command returns a collection of newly created pin objects.

```
create_pin u1/A[5:1]  
{u1/A[5] u1/A[4] u1/A[3] u1/A[2] u1/A[1]}
```

The following example introspects the direction attribute of the four newly created pin objects.

```
get_attribute_value_list [create_pin u1/C[3:0] -direction output] -name direction  
{output output output output}
```

[get_icl_pins](#)

[get_nets](#)

create_port

Context: dft

Mode: insertion

Creates a port on the specified design module.

Usage

```
create_port port_name [-on_module obj_spec] [-direction input | output | inout]
[-ascending] [-allow_existing] [-silent]
```

Description

By default, this command creates a port on the design module in the current design. If you specify the `-on_module` argument, this command creates a port on the module specified in `obj_spec`.

This command returns a collection of the port objects created; if `port_name` is a bus, this command returns a collection with one port object for each bus bit, beginning with the left-most bit of the bus and ending with the right-most.

If the specified port already exists the tool generates an error. You can specify the `-silent` switch to instruct the tool not to generate an error.

Arguments

- ***port_name***
A required value that specifies the name of the port to be created. Bus ports must be created with a single `create_port` command where `port_name` includes the required bus range.
- `-on_module obj_spec`
An optional switch and value pair that specifies the module to which the port is to be added. The `obj_spec` can be the name of a module or a module object returned by the `get_module` command. If the `-on_module` switch is not specified, this command adds the port to the current design, which is the module specified by the `set_current_design` command. You cannot create a port on a module that was read in from a file and that is not instantiated inside the current design. It is possible to create ports on modules created with the `create_module` command.
- `-direction input | output | inout`
An optional switch and literal pair that specify the direction of the newly created port. An input port is created when this option is omitted.
- `-ascending`
An optional switch that specifies the range direction type for a VHDL bus port. By default, the range direction type is inferred as “downto” when the left index is larger than the right index, and as “to” when the left index is smaller than the right index. You use this switch to specify that the VHDL port notation is “to” when the left index is equal to the right index;

create_port

otherwise, the tool uses the “downto” range direction type. An error is generated if you specify this option and the left index is larger than the right index, or if the object name is not a bus. The -ascending option is only permitted in the rtl context.

- -allow_existing

An optional switch specifying that if a port with a given name exists, the tool returns that port instead of issuing an error.

- -silent

An optional switch that specifies to not generate an error message if the specified port_name already exists. When an error is suppressed, the command returns an empty collection.

Examples

Example 1

The following example creates a 5-bit bus input port called A on the module that is the current design. The command returns a collection of the newly created port objects.

```
create_port A[5:1]  
{A[5] A[4] A[3] A[2] A[1]}
```

Example 2

The following example creates a scalar output port called B on module ModB.

```
create_port B -on_module ModB -direction output  
{B}
```

Example 3

The following example creates a 4-bit bus output port called C on the current design and uses the get_attribute_value_list command to query the direction attribute of the newly created port objects.

```
get_attribute_value_list [create_port C[3:0]] -name direction  
{input input input input}
```

create_reversible_patterns

Context: patterns -scan, patterns -scan_diagnosis

Mode: analysis

Generates reversible test patterns.

Usage

```
create_reversible_patterns -shift_direction_port shift_direction_port  
    -output output_pattern_file -pattern_format {STIL | WGL}  
    -begin_pattern integer -end_pattern integer  
    [ -test_setup_off ] [ -chain_mask chain_mask_file_location ]  
    -reverse_scan_config reverse_scan_config_file_location  
    [ -bidi_port ]
```

Description

Use this command to generate reversible test patterns.

Arguments

- **-shift_direction_port** *shift_direction_port*
A required switch and string that specifies the name of the port used to change the direction of the reversible chain.
- **-output** *output_pattern_file*
A required switch and string that specifies the name of the output pattern file.
- **-pattern_format** {STIL | WGL}
A required switch and string that specifies the format of the output pattern file. Allowed values are STIL and WGL.
- **-end_pattern** *integer*
A required switch and integer that specifies the end of the chain pattern set range to be extended into reversible patterns.
- **-begin_pattern** *integer*
A required switch and integer that specifies the beginning of the chain pattern set range to be extended into reversible patterns.
- **-test_setup_off**
An optional switch that specifies to exclude test setup chain patterns from the reversible pattern set.
- **-chain_mask** *chain_mask_file_location*
An optional switch and string that specifies the location of a text file that lists the chains to mask.

- `-reverse_scan_config reverse_scan_config_file_location`
A required switch and string that specifies the location of input scan path report (.spr) file.
- `-bidi_port`
An optional switch that specifies if the shift direction port is part of the bidirectional port declarations.

create_scan_chain_family

Context: dft -scan

Mode: analysis

Creates a scan_chain_family object, which controls how one or more scan chains are allocated/connected during distribution.

Usage

create_scan_chain_family *family_name*

```

{ -include_elements obj_spec | -ordered_elements obj_spec }
[ -edt_instances obj_spec |
{ -ssh_instance obj_spec [-ssh_chain_groups ssh_chain_group_list]} |
{ -si_connections obj_spec -so_connections obj_spec } ]
[ -si_associated_ports obj_spec -so_associated_ports obj_spec ]
[ -attribute_set_for_chain_assembly { attribute_list } ]
[ -single_attribute_set_chains { on | off } ]
[ -single_class_chains { on | off } ]
[ -single_clock_domain_chains { on | off } ]
[ -single_clock_edge_chains { on | off } ]
[ -single_power_domain_chains { on | off } ]
[ -single_cluster_chains { on | off } ]
[ -single_wrapper_type_chains { On | Off } ]
[ -port_index_start_value integer ]
[ -port_scalar_index_modifier integer ]
[ -chain_length { integer | unlimited } ]
[ -chain_count { integer | unlimited } ]
[ -si_port_format format ]
[ -so_port_format format ]
[ -si_timing { leading_edge | trailing_edge | any_edge } ]
[ -so_timing { leading_edge | trailing_edge | any_edge } ]
[ -lockup_cell_type { latch | flop } ]
[ -si_lockup_cell_type { latch | flop } ]
[ -so_lockup_cell_type { latch | flop } ]
[ -unused_edt_pin_handling { auto | insert_pipelining_flop | tie_compactor_input } ]
[ -si_pipelining { wrapper_chains_only | all_chains | off } ]
[ -si_pipelining_type { non_scan_flop | holding_scan_flop } ]

```

Description

Use this command to create a scan_chain_family object, which controls how one or more scan chains are allocated/connected during distribution. This is an optional/advanced command that enables you to fine-tune how sub-populations of a mode get treated.

Refer to [Chain Port Sharing](#) and [Scan Chain Family](#) in the *Tessent Scan and ATPG User's Manual* for usage examples.

Arguments

- ***family_name***
A required string that specifies a scan chain family name.
- **-include_elements *obj_spec***
A required switch (if -ordered_elements is not used) and value pair that specifies a list of mandatory scan elements to include in this chain family. It has no default value.
- **-ordered_elements *obj_spec***
A required switch (if -include_elements is not used) and value pair that specifies an ordered list of mandatory scan elements to include in this chain family. It has no default value.
- **-edt_instances *obj_spec***
A switch and value pair that specifies EDT instances to connect the scan chains to. When core descriptions for the specified instances are detected, then the tool automatically sets the -si/so_connections to the instances scan pins.
- **-ssh_instance *obj_spec* [-ssh_chain_groups *ssh_chain_group_list*]**
Optional string and literal pair to enable you to identify a single ScanHost node instance for the add_scan_mode command. When the tool detects a core description for the specified instance, it automatically sets the -si/so_connections to the scan pins of the instance.
-ssh_chain_groups *ssh_chain_group_list* — specify one or more subsets of the ScanHost connections using the SSH chain group ID(s). All ScanHost connections are selected when no SSH chain group ID is specified.
- **-si/so_connections *obj_spec***
A switch and value pair that specifies connections to existing SI/SO pins or ports. The specified value can be a Tcl list of one or more port/pin names, a collection of one or more pin/port objects, or a port/pin Verilog name (of a certain width). The specified values corresponds to existing top-level input port(s) or output pin(s) for -si_connections and existing top-level output port(s) or input pin(s) for -so_connections.
- **-si_associated_ports *obj_spec* -so_associated_ports *obj_spec***
Optional string and literal pairs that specify existing top-level port(s) associated to the internal connections identified using -si/so_connections. These are used in the .tcd file to describe the scan ports of the chains at the core boundary.
- **-attribute_set_for_chain_assembly { *attribute_list* }**
An optional switch used to specify one or more string attributes to control scan chain assembly. When you use this switch and specify several string attributes, the tool creates clusters for every value combination of the specified attributes. For example, assume that

you have defined the following quadrant and testpoint_type name attributes and that all scan elements are attributed accordingly:

```
>register_attribute \  
-name quadrant \  
-value_type string \  
-object_types scan_element \  
-enum { NE NW SE SW }  
  
>register_attribute \  
-name testpoint_type \  
-value_type string \  
-object_types scan_element \  
-enum { control observation }
```

Scan elements that are not test points are not assigned a “testpoint_type” attribute value, whereas all scan elements are assigned a “quadrant” attribute value. This implies that each scan element has one of the following attribute value combinations:

Table 3-20. Attribute Value Combinations

“quadrant” attribute value	“testpoint_type” attribute value
NE	control
NE	observation
NE	--
NW	control
NW	observation
NW	--
SE	control
SE	observation
SE	--
SW	control
SW	observation
SW	--

Accordingly, you can specify a scan chain family that creates separate scan chains for each of the above 12 attribute value combinations as follows:

```
>create_scan_chain_family foo \  
-attribute_set_for_chain_assembly { quadrant testpoint_type }
```

- -single_attribute_set_chains { on | off }

An optional switch and literal pair that restricts a scan chain to a single set of attribute values. The default is on.

- `-single_class_chains { On | Off }`

An optional string and literal pair that controls whether to mix wrapper and non-wrapper cells in a single chain. By default, the tool keeps wrapper cells separate from non-wrapper chains for internal and external type of scan modes. However, for unwrapped mode they can be mixed.
- `-single_clock_domain_chains { On | Off }`

An optional string and literal pair that specifies whether to restrict a scan chain to a single clock domain. The default is off.
- `-single_clock_edge_chains { On | Off }`

An optional string and literal pair that specifies whether to restrict a scan chain to cells having a single edge. The default is off.
- `-single_power_domain_chains { On | Off }`

An optional string and literal pair that specifies to restrict a scan chain to a single power domain using the built-in attribute “power_domain_name”. The default is off. For attribute details, refer to the table “Built in Attributes on Scan Element (SE) Object Type” in the [Scan Element Object Type](#) section of the *Tessent Shell Reference Manual*.
- `-single_cluster_chains { On | Off }`

An optional string and literal pair that specifies to restrict a scan chain to a single cluster using the built-in attribute “cluster_name”. The default is on. For usage examples, refer to [Scan Mode](#) and [Scan Insertion for Unwrapped Core](#) sections in the *Tessent Scan and ATPG User’s Manual*. For attribute details, refer to the table “Built in Attributes on Scan Element (SE) Object Type” in the [Scan Element Object Type](#) section of the *Tessent Shell Reference Manual*.
- `-single_wrapper_type_chains { On | Off }`

An optional switch and literal pair that specifies that “-single_class_chains ON” controls whether to mix input wrapper and output wrapper cells in the same chain. The default is off.
- `-port_index_start_value integer`

An optional switch and integer that specifies the starting port index. The starting index is 0 by default, but can be overridden by this option.
- `-port_scalar_index_modifier integer`

An optional switch and integer that specifies the increment used between each chain port indices, the default is 1.
- `-chain_length { integer | unlimited }`

An optional integer that specifies the target length of scan chains for a particular chain family. By default, the no limit (unlimited) is imposed on the chain length. The minimum scan chain length is 1.

- `-chain_count { integer | unlimited }`

An optional integer that specifies the number of scan chains that should be constructed for the specified chain family. By default, the chain count is set to the number of connections specified with the `-si/so_connections` or by the number of pins of the EDT controller(s) specified with the `-edt_instances` option, otherwise if the latter options were not used, then no limit (unlimited) is imposed on the chain count.

- `-si/so_port_format format`

An optional string that specifies the port format. The default `si/so_port_format` is set to `"ts_%s_si/so[%d]"` when there are more than one scan mode, otherwise it defaults to `"ts_si/so[%d]"`. The mode placeholder `"%s"` gets replaced by the chain mode name, whereas the index placeholder `"%d"` gets substituted by the chain index. A precision number may be used when specifying the index placeholder, for example the format `"lsi_si%2d"` would cause port names such as `"lsi_si00"`, `"lsi_si01"` to be created. Note that leading zeros are inserted automatically when needed making `"%2d"` implicitly equivalent to `"%02d"`.

- `-si_timing { leading_edge | trailing_edge | any_edge }`

An optional string and literal pair that provides the ability to control the capture edge of the first scan cell in a chain. The tool inserts a lockup (re-timing) cell between the scan chain input pin and the first scan cell in the chain to control the capture edge of the first cell as leading or trailing edge. No lockup cell is inserted if `"any_edge"` is provided as the argument. The default edge type is `leading_edge`.

- `-so_timing { leading_edge | trailing_edge | any_edge }`

An optional string and literal pair that provides the ability to control the change edge of the last scan cell in a chain. The tool inserts a lockup (re-timing) cell between the scan chain output pin and the last scan cell in the chain to control the change edge of the last cell as leading or trailing edge. No lockup cell is inserted if `"any_edge"` is provided as the argument. The default edge type is `trailing_edge`.

- `-lockup_cell_type { latch | flop }`

An optional switch and string that controls the type of lockup (re-timing) cell to use between timing-constrained scan elements of new scan chains. The default cell type is `latch`

- `-si_lockup_cell_type { latch | flop }`

An optional switch and string that controls the type of lockup (re-timing) cell to use between the scan chain input pin and the first scan cell. The default cell type is `latch`

- `-so_lockup_cell_type { latch | flop }`

An optional switch and string that controls the type of lockup (re-timing) cell to use between the scan chain output pin and the last scan cell. The default cell type is `latch`.

Note

 By default, the tool adds a pipeline flop in front of the wrapper chains to facilitate launching a transition from the first scan cells in the wrapper chains.

- `-unused_edt_pin_handling { auto | insert_pipelining_flop | tie_compactor_input }`
An optional switch that selects how to handle unused EDT chain pins. Options are:
 - `insert_pipelining_flop` — inserts scan chains composed of a single pipelining flop.
 - `tie_compactor_input` — ties-off the EDT compactor.
 - `auto` — selects “`insert_pipelining_flop`” for EDT controllers with bypass chains, and “`tie_compactor_input`” for all other EDT controllers. This is the default.
- `-si_pipelining { wrapper_chains_only | all_chains | off }`
An optional switch and string that controls whether a pipelining flop gets inserted at the beginning of chains. When set to `all`, all scan chains get a pipelining flop. When set to `wrapper_chains_only`, then only chains of internal or external mode types and composed of wrapper scan elements get a pipelining flop. The default is `wrapper_chains_only`
- `-si_pipelining_type { non_scan_flop | holding_scan_flop }`
An optional switch and string that controls whether to implement pipelining using a simple non-scan data flop or a holding flop constructed using a scan flop with its output connected to its data input. The default is `holding_scan_flop`.

create_scan_segment

Context: dft -scan

Mode: analysis

Creates a spec scan segment that enables you to force sequences of scan elements to be stitched together within scan chains.

Usage

```
create_scan_segment spec_segment_name
    {-include_elements <obj_spec> | -ordered_elements <obj_spec> }
    [ -head_elements <obj_spec> ]
    [ -tail_elements <obj_spec> ]
```

Description

You can use this command to create a spec segment, which is a virtual segment that does not exist physically but which you can specify logically. It is a non-dividable scan element of type “segment” that has its “exists” attribute set to false (in contrast, the attribute is set to true for the existing scan segment). Another distinction from an existing scan segment is that the scan elements inside the spec segment are not scan connected, the tool does this during scan insertion.

You can define spec segments during the system mode analysis by specifying usable scan element leaves and segments. Scan elements included inside a spec segment get the status “usable_indirectly”.

The tool treats spec segments in the same manner as existing segments during wrapper analysis. Accordingly, if a spec segment contains elements of mixed classes, then the tool automatically promotes any of its “core” elements to “wrapper” elements.

Note

 If you create or delete spec segments after analyze_wrapper_chains and/or analyze_scan_chains, it triggers the reset of the rest of the wrapper analysis and/or distribution model.

Arguments

- **spec_segment_name**
A required string that specifies the name of the spec segment to create.
- ***-include_elements* <obj_spec>**
An optional switch that specifies a list of required scan elements to include in the segment. The tool manages the ordering for the segment and may reorder the elements during scan insertion to minimize the use of retiming elements.

create_scan_segment

- **-ordered_elements <obj_spec>**
An optional switch that specifies an ordered list of required scan elements to include in the segment.
- **-head_elements <obj_spec>**
An optional switch that specifies a specific subset of ordered elements at the beginning of the segment.
- **-tail_elements <obj_spec>**
An optional switch that specifies a specific subset of ordered elements at the end of the segment.

Examples

Example 1

This example creates a spec segment with three flops ordered in a specific manner.

```
ANALYSIS> create_scan_segment my_ordered_segment \  
-ordered_elements { /df_03 /df_02 /df_01 }
```

Example 2

This example creates a spec segment that begins with three flops ordered in a specific manner, followed by the flops found below instance B_i (which are ordered by the tool to minimize the insertion of retiming cells).

```
ANALYSIS> create_scan_segment my_complex_segment \  
-head_elements { /df_04 /df_05 /df_06 } \  
-include_elements [get_scan_elements -below_instances B_i]
```

create_silicon_insight_setup_specification

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Generates a default Tessent SiliconInsight setup specification.

Usage

create_silicon_insight_setup_specification [-setup *mode_name*]

Description

Generates a default Tessent SiliconInsight setup specification wrapper called SiliconInsightSetupSpec and saves it to the current working directory in a file named *SiliconInsightSetupSpec.cfg*.

The command returns the name of created specification. For example:

```
set si_spec [create_silicon_insight_setup_specification]
set_config_value [get_config_elements selected_setup \
    -in_wrapper $si_spec] Sid(signalalyzerH4)
```

The setup specification contains Tessent SiliconInsight-specific data that defines the pin map, testers, adaptor types, and other data that are required to prepare Tessent SiliconInsight to communicate with a DUT, simulator process, or ATE.

By default, the tool generates a specification that includes all possible setups and with No_Tester(batch_cdp) as the current setup. (This mode enables generating a CDP only.) Specify the -setup option to generate the default setup specification only for the mode you specify.

For information about the Tessent SiliconInsight setup specification, refer to “[Prepare the Design Under Test](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

Arguments

- -setup *mode_name*

An optional switch and string pair that specifies to create a default setup specification for the specified Tessent SiliconInsight Desktop mode of operation. For *mode_name*, you can specify:

```
jtagkey
flyswatter2
olimex_arm_usb_ocd
olimex_arm_usb_ocd_h
signalalyzer
signalalyzerSHA40
```

signalyzerH2
 signalyzerH4
 signalyzerSP
 opalKellyXem6310
 simdut

Examples

The following example creates a setup specification to use the Tin Can Tools Flyswatter2 adaptor as the Tessent SiliconInsight Desktop connection to the performance board.

create_silicon_insight_setup_specification -setup flyswatter2

The tool generates SiliconInsightSetupSpecification with the default properties for this adaptor, which you can edit as needed. For details about the SiliconInsightSetupSpecification configuration data syntax, refer to “[SiliconInsightSetupSpecification](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

```

SiliconInsightSetupSpecification {
  selected_setup : Sid(flyswatter2);
  Protocol {
    SvftapPins {
      TRST : trst;
      TDI : tdi;
      TMS : tms;
      TDO : tdo;
      TCK : tck;
    }
  }
  Sid(flyswatter2) {
    cdp_directory : top.cdp;
    flyswatter2 {
      PinMap {
        TDI : tdi;
        TMS : tms;
        TDO : tdo;
        TCK : tck;
      }
    }
  }
}

```

create_ssn_continuity_patterns

Context: patterns -ijtag

Mode: analysis

Creates an SSN continuity pattern to test the internal path of the ScanHost from input to output.

Usage

```
create_ssn_continuity_patterns [-include_ssh_icl_instances included_ssh_instances]  
    [-ssn_datapath_ids ssn_datapath_ids]  
    [-custom_pattern_sequence custom_pattern_sequence]  
    [-verify_datapaths_simultaneously {on | off}]
```

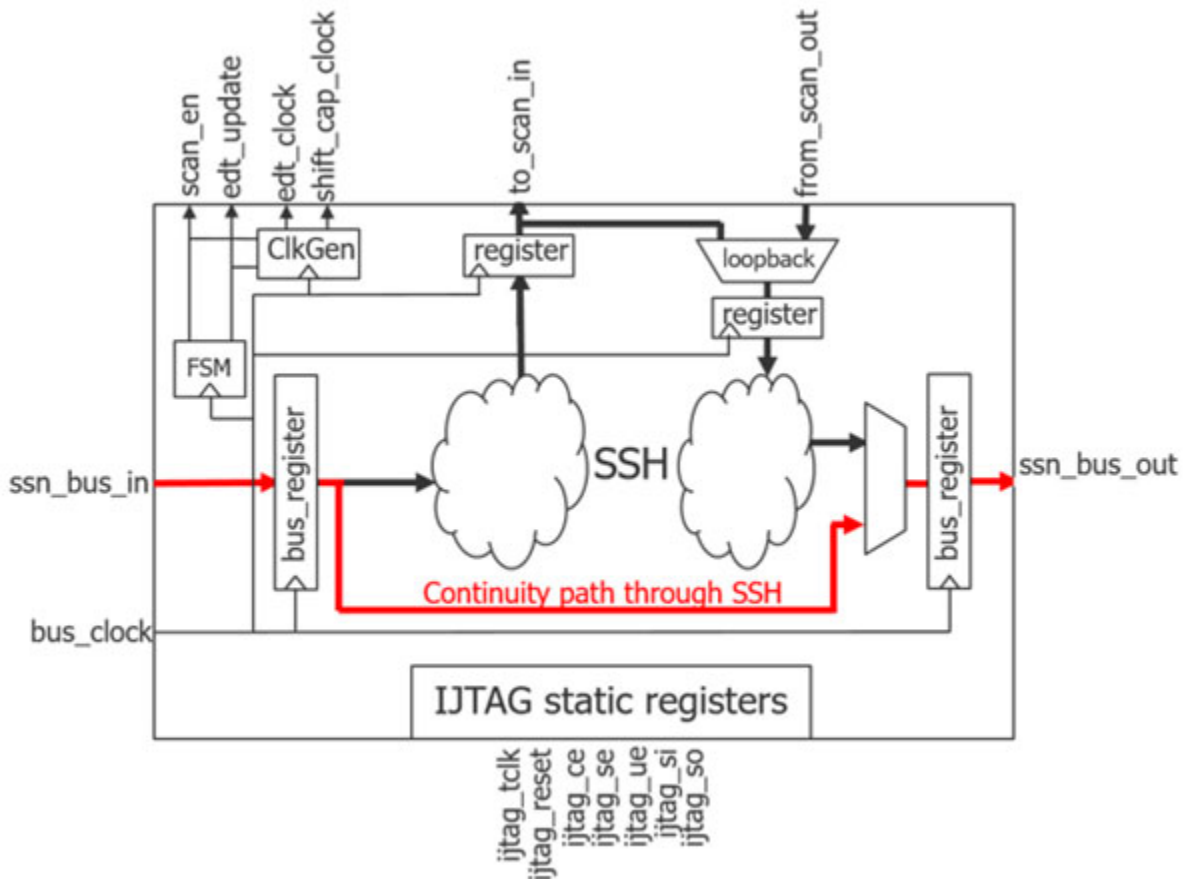

Description

The continuity pattern verifies the SSN datapath. SSN datapaths from `ssn_bus_in` to `ssn_bus_out` are verified at the chip level. A new run of `create_ssn_continuity_patterns` is required after you configure each datapath. You can also run the SSN continuity pattern at the block level.

The continuity pattern detects deviations in the lengths of the datapaths and accidental shuffling of the datapath bits. It is not SSN packetized scan data.

[Figure 3-30](#) shows the path through the ScanHost node.

Figure 3-30. SSN Continuity Pattern - Internal SSH Paths Coverage

To create the continuity patterns with an existing process_patterns_specification framework, use the create_ssn_continuity_patterns command between [open_pattern_set](#) and [close_pattern_set](#). This method stores the results of the pattern generation in an IJTAG pattern set. Use the [write_patterns](#) command to save those patterns.

At the chip level, you can use [iWrite](#) and [iApply](#) to configure the SSN Multiplexer node and change the SSN datapath configuration for the continuity pattern.

Note

Use [iCall](#) instead of [iWrite](#) if an iProc encapsulates the datapath configuration.

Arguments

- `-include_ssh_icl_instances included_ssh_instances`

By default, the create_ssn_continuity_patterns command uses all accessible ScanHost instances. Using this optional switch restricts the pattern generation to the datapaths that are required to access the instances you specify with *included_ssh_instances*. The instances you specify in *included_ssh_instances* must be valid ScanHost instances by instrument type and subtype.

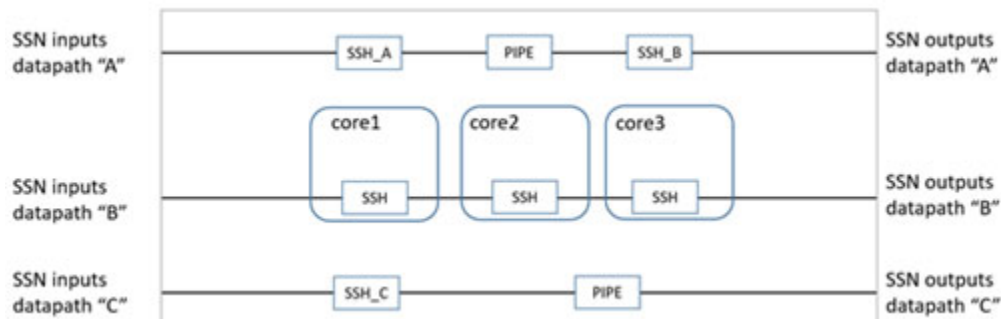

- `-ssn_datapath_ids ssn_datapath_ids`
 By default, this optional switch uses all accessible SSN datapaths. Using this switch restricts the pattern generation to the datapath IDs you specify in `ssn_datapath_ids`. The ICL must specify the datapath IDs as values of the `tessent_ssn_datapath_ids` attribute on the primary datapath bus inputs and outputs.
- `-custom_pattern_sequence custom_pattern_sequence`
 By default, the continuity pattern data is a random bit sequence. Using this optional switch enables you to specify that pattern data sequence. If the sequence you define in `custom_pattern_sequence` is shorter than the active SSN datapath, the sequence repeats from the beginning.
- `-verify_datapaths_simultaneously on | off`
 Set this optional switch to “off” to test SSN datapaths sequentially. By default, all SSN datapaths are tested simultaneously.

Examples

Example 1

The following example shows how you can use the `-include_ssh_icl_instances` option to limit the test pattern generation to a subset of the SSH instances. [Figure 3-31](#) shows an example design with multiple datapaths.

Figure 3-31. SSN With Multiple Datapaths

```
set_context patterns -ijtag
...
open_pattern_set ssn_verification1 -usage ssn
  create_ssn_continuity_patterns -include_ssh_icl_instances \
    {core1.SSH core3.SSH SSH_C}
close_pattern_set
write_patterns SSNContinuity.stil -pattern_sets ssn_verification1 -stil -replace
```

The generated test vectors contain stimuli and responses for the ports of the datapaths “B” and “C” only because this is the minimal set of datapaths that contains all of the specified SSH instances. The SSH instance `core2.SSH` is also included in the test because it is on datapath “B” and hence cannot be avoided.

Example 2

The following example shows how you can use the `-ssn_datapath_ids` and `-verify_datapaths_simultaneously` options to test multiple datapaths one after another. Refer to [Figure 3-31](#).

```
set_context patterns -ijtag
...
open_pattern_set ssn_verification2 -usage ssn
  create_ssn_continuity_patterns -ssn_datapath_ids {A B} \
    -verify_datapaths_simultaneously off
close_pattern_set
write_patterns SSNContinuity.stil -pattern_sets ssn_verification2 -stil -replace
```

The `-ssn_datapath_ids` option instructs the tool to limit the pattern generation to the specified datapaths “A” and “B.” Setting `-verify_datapaths_simultaneously` to “off” forces the tool to test those datapaths in series.

Example 3

The following chip-level example shows how you can call `create_ssn_continuity_patterns` twice to generate continuity patterns for the default SSN datapath configuration and an alternative configuration.

Figure 3-32. Example Design With Two SSN Datapath Configurations

```
set_context patterns -ijtag
...
open_pattern_set ssn_continuity_default -usage ssn
  # Select the default datapath (path 0 of bypass_mux)
  create_ssn_continuity_patterns
  # Select the secondary datapath (path 1 of bypass_mux)
  iCall <bypass_mux_inst>.setup select_secondary_bus 0b1
  iApply
  create_ssn_continuity_patterns
close_pattern_set
write_patterns SSNContinuity.stil -pattern_sets ssn_continuity_default \
  -stil -replace
```

deassert_icl_sib

Context: patterns -silicon_insight -ijtag

Mode: setup

Configures the SIB to pick the client input.

Usage

```
deassert_icl_sib sib_name
```

Description

Use this command when you are configuring a scan path in the IJTAG network. The specified SIB is held at 0 in the scan path.

Use this command when manually debugging IJTAG networks as described in “[Diagnosing and Debugging IJTAG Networks](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

Arguments

- *sib_name*
A required variable that specifies the name of the SIB.

Examples

```
deassert_icl_sib sib_I4
```

defer_schematic_updates

Context: all contexts

Modes: all modes

Postpones schematic updates until after the scope introduced by the command ends.

Usage

defer_schematic_updates *commands* [-silent]

Description

Defers execution of the given commands until the scope returns to that within which the defer_schematic_updates command was issued.

Arguments

- *command...*
A list of commands to run.
- *-silent*
An optional switch that suppresses display of the commands run.

Examples

The following example adds a design object and a design connection to the Hierarchical Schematic window, after the scope returns to that within which the defer_schematic_updates command was issued.

```
defer_schematic_updates {  
  add_schematic_objects bsr_i1 -disp hier  
  add_schematic_connections cour_i/out[3] -to tap_i/in[3] -disp hier  
}
```

delete_atpg_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Removes state restrictions from the specified pins.

Usage

```
delete_atpg_constraints {pin_pathname | gate_ID# | {function_name |  
  {-Cell cell_name {pin_name...}}}... [-Instance {object_expression...}]  
[-MODULE {module_name ...}]... | -All
```

Description

Define pin restrictions by using the [add_atpg_constraints](#) command.

If you change ATPG constraints, create patterns with those changed constraints, and then compress patterns, all patterns not meeting the new constraints are rejected. This can cause the good patterns created with the old constraints to be rejected; therefore, use the `delete_atpg_constraints` command to remove all ATPG constraints before compressing the pattern set.

Arguments

- ***pin_pathname***
A repeatable string specifying the pathname of the pin from which to remove any ATPG pin constraints.
- ***gate_ID#***
A repeatable integer specifying the gate identification number of the gate from which to remove any ATPG pin constraints.
- ***function_name***
A repeatable string specifying the name of a function created with the `add_atpg_functions` command and from which to remove any ATPG pin constraints.
- **-Cell *cell_name* {*pin_name*}**
A repeatable switch and string pair that removes ATPG constraints from the specified pin on the DFT library cell. You can repeat the *pin_name* argument if there are multiple pins or nets on a cell that have ATPG constraints you need to remove.
- **-Instance *object_expression***
An optional switch and repeatable string pair that removes ATPG constraints inside the specified list of instances. You can use regular expressions, which may include any number of embedded asterisk (*) and question mark (?) wildcard characters. You can only use this switch when using the -Cell option or when a function name is specified.

- **-MODULE** *module_name*
An optional switch and repeatable string pair that removes the ATPG constraints inside all instances of the specified module.
- **-All**
A switch that removes all current, user-defined ATPG constraints from all objects.

Examples

Example 1

The following example creates two user-defined ATPG pin constraints, runs the ATPG process, removes all ATPG constraints, and then compresses the pattern set:

```
set_system_mode analysis  
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q  
add_atpg_constraints 0 /i$135/q  
add_atpg_constraints 1 and_b_in  
create_patterns  
delete_atpg_constraints -all  
compress_patterns
```

Example 2

The following Tessent FastScan example shows how to use wildcards.

```
add_atpg_constraints 1 -cell mux21 Y -ins uALU*/ix184  
report_atpg_constraints  
  
1 dynamic /uALU/u3/ix184/Y (4400) .  
1 dynamic /uALU/u2/ix184/Y (4406) .  
1 dynamic /uALU/u1/ix184/Y (4412) .  
  
delete_atpg_constraints -cell mux21 Y -ins uALU/u1/*  
report_atpg_constraints  
  
1 dynamic /uALU/u3/ix184/Y (4400) .  
1 dynamic /uALU/u2/ix184/Y (4406) .
```

[add_atpg_functions](#)

[report_atpg_constraints](#)

delete_atpg_functions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Removes the specified function definitions.

Usage

delete_atpg_functions *function_name*... | **-All**

Description

The delete_atpg_functions command lets you delete_atpg_functions defined with the [add_atpg_functions](#) command. You cannot remove an ATPG function if an ATPG constraint is currently using that function. If you attempt to remove an in-use function, the tool generates an error. Therefore, if you need to delete an in-use ATPG function, you must first remove all the associated ATPG constraints using the delete_atpg_constraints command; then you can remove the ATPG function.

You can display a list of the current ATPG functions that the tool is using as ATPG constraints by using the report_atpg_constraints command.

Arguments

- *function_name*
A repeatable string that specifies the names of the ATPG functions that you want to delete.
- **-All**
A switch that removes all ATPG function definitions.

Examples

The following example creates two user-defined ATPG functions, one user-defined ATPG constraint, displays the currently-in-use ATPG constraints, and then removes one of the inactive ATPG functions:

```
add_atpg_functions and_b_in And /i$144/q /i$141/q /i$142/q
add_atpg_functions select_b_in select /i$144/q /i$142/q
add_atpg_constraints 0 /i$135/q
report_atpg_constraints

0 /$135/Q (23)

delete_atpg_functions and_b_in
```

delete_bist_capture_ranges

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies that the tool no longer uses a particular named capture procedure when generating BIST patterns.

Usage

delete_bist_capture_ranges *capture_proc_name* | **-All**

Description

Specifies that the tool no longer uses a particular named capture procedure when generating BIST patterns.

Arguments

- *capture_proc_name*
A required string that specifies the name of the capture procedure.
- **-All**
A switch that specifies that the tool no longer use any named capture procedures when generating BIST patterns.

Related Topics

[add_bist_capture_range](#)

[report_bist_capture_ranges](#)

delete_black_boxes

Context: all contexts

Mode: setup

Undoes the effect of the `add_black_boxes` command.

Usage

`delete_black_boxes` **-Instances** [*ins_pathnames*] | **-Modules** [*module_names*] | **-All**

Description

Undoes the effect of the `add_black_boxes` command.

For a module that was originally modeled, removing the effect of the `add_black_boxes` command reinstates the original model. Specified tied values are no longer set on the output pins. For a module that was empty or undefined in the input netlist, the output pins revert to the default tied value of X.

Note

The tool releases the flat model if one exists at the time you issue this command.

Arguments

- **-Instances** [*ins_pathnames*]
A switch that specifies for the tool to undo the effect of the `add_black_boxes` command on all instances specified by the *ins_pathnames* argument. The *ins_pathnames* argument can be a Tcl list of one or more instances, or a collection of one or more instances. If you do not specify the *ins_pathname*, the tool undoes the effect of the `add_black_boxes` command on all instance-based blackboxes.
- **-Modules** [*module_names*]
A required switch that specifies for the tool to undo the effect of the `add_black_boxes` command on all instances of the Verilog module or Tessent Cell library model specified by the *module_names* argument. The *module_names* argument can be a Tcl list of one or more modules, or a collection of one or more modules. If you do not specify the *module_names* argument, the tool undoes the effect of the `add_black_boxes` command on all module-based blackboxes.
- **-All**
A required switch that specifies for the tool to undo the effect of the `add_black_boxes` command on all blackboxes.

Examples

Example 1

The following example adds the black box for module “core” then undoes all blackboxes that were defined.

```
add_black_boxes -modules core 1  
delete_black_boxes -all
```

Example 2

The following example deletes blackboxes for the collection of modules returned by the `get_modules` command. The `get_modules` command returns only those modules that have been marked by the user with the user-defined attribute `mark_black_box`.

```
delete_black_boxes -modules [get_modules -filter mark_black_box]
```

Related Topics

[add_black_boxes](#)

[report_black_boxes](#)

delete_capture_procedures

Context: dft -edt, patterns -scan

Mode: analysis

Removes the specified capture procedures from internal memory.

Usage

```
delete_capture_procedures {-All | -Created_capture_procedures |  
-Loaded_capture_procedures | -Disabled | procedure_name...}
```

Description

The `delete_capture_procedures` command deletes all or specific named capture procedures from the internal tool memory. A named capture procedure used by the current pattern set cannot be deleted.

Arguments

- **-All**
A switch that deletes all the named capture procedures.
- **-Created_capture_procedures**
A switch that deletes all the named capture procedures automatically created by the tool.
- **-Loaded_capture_procedures**
A switch that deletes all the named capture procedures loaded using the [read_procfile](#) command or from procedure files associated with the scan group definition.
- **-Disabled**
A switch that deletes all the disabled named capture procedures.
- ***procedure_name***
A repeatable string that specifies a named capture procedure to delete.

Examples

Example 1

The following example deletes all capture procedures.

```
delete_capture_procedures -All
```

Example 2

The following example removes the capture procedure named `user_capture_proc1`.

```
delete_capture_procedures user_capture_proc1
```

Related Topics

[set_capture_procedures](#)

delete_cdp_test

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Removes the specified test from the CDP.

Usage

`delete_cdp_test test_name`

Arguments

- *test_name*
A required string that specifies the name of a CDP test.

Examples

The following example removes the test1 CDP test:

```
delete_cdp_test test1
```

Related Topics

[add_cdp_test](#)

delete_cell_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Removes constraints placed on scan cells.

Usage

```
delete_cell_constraints -All | pin_pathname | {chain_name cell_position} | {-Drc C6} |  
{-CHain chain_name} | {-CLock clock_name}
```

Description

The delete_cell_constraints command deletes the constraints placed on scan cells using the [add_cell_constraints](#) command. You can specify a scan cell by using either a pin pathname or a position in a scan chain.

Arguments

- **-All**
A switch that, in Setup mode, specifies to delete all constraints from all scan cells. In analysis mode, it specifies to delete all cell constraints that were added in non-Setup modes.
- ***pin_pathname***
A string that specifies the name of an output pin that directly connects to a scan memory element (you can only specify output pins of buffers and inverters). Valid in Setup mode only.
- ***chain_name cell_position***
A string and integer pair that specifies the name of a currently-defined scan chain and the position of the cell in the scan chain. The *cell_position* is an integer where 0 is the scan cell closest to the scan-out pin. Valid in Setup mode only.
- **-Drc C6**
A switch and literal pair that specifies to delete all cell constraints added by “add_cell_constraints -drc c6”. Valid in analysis mode only.
- **-CHain *chain_name***
A switch and string pair that specifies to delete all cell constraints added by the -Chain argument to the add_cell_constraints command. Valid in analysis mode only.
- **-CLock *clock_name***
A switch and string pair that specifies to delete all cell constraints added by the -Clock argument to the add_cell_constraints command. Valid in analysis mode only.

Examples

The following example deletes an incorrectly added cell constraint placed on a scan cell:

```
add_clocks 1 clock1
add_scan_groups group1 proc.g1
add_scan_chains chain1 group1 scanin1 scanout1
add_scan_chains chain2 group1 scanin2 scanout2
add_cell_constraints chain1 5 c0
add_cell_constraints chain2 3 c1
delete_cell_constraints chain2 3
add_cell_constraints chain2 4 c1
report_cell_constraints
```

Related Topics

[add_cell_constraints](#)

delete_cell_library

Context: unspecified, all contexts

Mode: setup

Removes all current cell libraries, the current design including the flat model, and all tool data that is design-specific.

Usage

`delete_cell_library`

Description

This command also clears any Tessent Visualizer schematic or instance browser tabs.

When this command is deleting a flat model, and that flat model was saved with a list of enabled and turned off commands, then the restriction on the turned off commands is removed. In other words, all commands permitted in the tool are enabled for the next design.

Arguments

None

Examples

The following example removes all current cell libraries:

```
delete_cell_library
```

Related Topics

[delete_design](#)

delete_cell_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Specifies the name of the DFT library cell that the tool is to remove from the active list of cells that the user can access when adding test points or that the tool can access when inserting test logic.

Usage

```
delete_cell_models dftlib_model... | {-Type {INV | And | Buf | OR | NAnd | NOr | Xor | Mux  
| Scancell | DFf | LATCH}} | -All
```

Description

Specifies the name of the DFT library cell that the tool is to remove from the active list of cells that the user can access when adding test points or that the tool can access when inserting test logic.

You originally added the cells to the active list with either the [add_cell_models](#) command or with the *cell_type* library attribute. If you remove a cell model from the active list, you only remove the cell from that list and do not change the DFT library.

If you accidentally delete a DFT library cell from the active list with the `delete_cell_models` command, you can add the specified cell back into the active list with the [add_cell_models](#) command.

Arguments

- *dftlib_model*

A repeatable string that specifies the names of the particular DFT library models that you want the tool to remove from the active list.

- **-Type INV | And | Buf | OR | NAnd | NOr | Xor | Mux | Scancell | DFf | LATCH**

A switch and argument pair that specifies the cell model type of all DFT library models that you want the tool to remove from the active list. The valid cell model types are as follows:

INV — A literal that specifies a one-input inverter gate.

And — A literal that specifies an AND gate.

Buf — A literal that specifies a one-input buffer gate.

OR — A literal that specifies an OR gate.

NAnd — A literal that specifies a NAND gate.

NOr — A literal that specifies a NOR gate.

Xor — A literal that specifies an exclusive OR gate.

Mux — A literal that specifies a 2-1 multiplexer.

Scancell — A literal that specifies a mux-scan D flip-flop.

Dff — A literal that specifies a D flip-flop.

LATCH — A literal that specifies a D latch.

- **-All**

A switch that removes all cell models from the active list, including those tagged in the DFT library with the *cell_type* attribute. This switch does not change the contents of the DFT library, only the active list within the tool.

Examples

The following example removes a DFT library model from the active list:

```
add_clocks 0 clk
set_test_logic -set on -reset on
set_system_mode analysis
add_cell_models and2 -type and
add_cell_models or2 -type or
add_cell_models mux21h -type mux s a b
add_cell_models nor2 -type nor
delete_cell_models or2
insert_test_logic
```

delete_chain_masks

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup and analysis when EDT is off

Mode: setup only when EDT or LBIST is on

Removes chain masks from the specified scan chains.

Usage

```
delete_chain_masks chain_name... | -INStance instance_name -Block_chain_index_list  
block_chain_index_list | -All
```

Description

The delete_chain_masks command deletes chain masks from the specified scan chains defined with the [add_chain_masks](#) command. You can delete the definitions of specific chain name or all chains.

Arguments

- ***chain_name***
A repeatable string that specifies the names of the chain mask definitions that you want to delete.
- ***-INStance instance_name -Block_chain_index_list block_chain_index_list...***
Required set of switches and values that specifies a core instance object_spec and the list of chain indices starting with “1” on the EDT controller.
- ***-All***
A switch that deletes all chain mask definitions.

Examples

The following example defines two chain masks then deletes all chain masks:

```
add_chain_masks chain2 chain3  
delete_chain_masks -all
```

Related Topics

[add_chain_masks](#)

[report_chain_masks](#)

delete_clocks

Context: all contexts

Mode: setup

Removes clocks from the clock list.

Usage

delete_clocks *pin_or_label_name*... | **-All**

Description

The delete_clocks command removes clocks from the clock list that you can specify by pin name or label name. If you delete an equivalence pin, the command also deletes all of the equivalent pins from the clock list.

If you want to change one or more options of a defined clock, you can use the [set_clock_options](#) command to modify the clock.

Arguments

- *pin_or_label_name*
A repeatable string that specifies the pin name or label name to delete from the clock list.
- **-All**
A switch that deletes all clocks from the clock list.

Examples

The following example deletes an incorrectly added clock from the clock list:

```
add_clocks 1 clock1
add_clocks 1 clock2
delete_clocks clock1
```

Related Topics

delete_config_element

Context: unspecified, all contexts

Mode: all modes

Deletes one or more configuration elements. Only elements that can be added can be deleted.

Usage

```
delete_config_element config_object | {config_name_list [-in_wrapper wrapper_object_spec]}
```

Description

Singular elements such as a wrapper declared with Repeatable set to single in the metadata and properties cannot be deleted as they always exist as soon as their parent wrapper exist.

Arguments

- *config_object*
A required collection containing one or more configuration elements. When using a collection of object, the -in_wrapper option cannot be used as the objects contains the full path of the object
- *config_name_list*
A required value that specifies a Tcl list containing names of one or more configuration elements. When the -in_wrapper option is specified, the names are relative to the specified wrapper element.
- -in_wrapper *wrapper_object_spec*
An optional value pair that is used to specify the parent wrapper in which the configuration elements are to be deleted. The *wrapper_object_spec* value is the name of a wrapper or a collection containing a wrapper element. The names in the *config_name_list* are relative to the specified *wrapper_object_spec*.

Examples

The following example deletes elements using the full name of elements, using a relative name with respect to a parent wrapper and using a collection of objects.

```
delete_config_element {  
  DftSpecification(mod1,rtl)/lntagNetwork/HostScanInterface(1)  
  DftSpecification(mod1,rtl)/lntagNetwork/HostScanInterface(2) }  
  
delete_config_element {HostScanInterface(1) HostScanInterface(2)} \  
-in_wrapper DftSpecification(mod1,rtl)/lntagNetwork  
  
> delete_config_element [get_config_elements HostScanInterface \  
-in DftSpecification(mod1,rtl)/lntagNetwork
```

Related Topics

[add_config_element](#)

[get_config_elements](#)

delete_config_messages

Context: all contexts

Mode: all modes

Deletes error, warning or info message that were added to configuration elements using the `add_config_message` command.

Usage

```
delete_config_messages config_object_spec  
    [-hierarchical] [-all | [-error] [-warning] [-info]] [-silent]
```

Description

Deletes error, warning or info message that were added to configuration elements using the `add_config_message` command.

Arguments

- *config_object_spec*
A required value that specifies a configuration object on which to delete the messages. The `config_object_spec` value is the name of a configuration element or a collection containing a single configuration element object.
- `-hierarchical`
An optional Boolean option that specifies that the config message should be deleted on the specified `config_object_spec` and all elements below it. The `-hierarchical` option is ignored when the `config_object_spec` is a property.
- `-all`
An optional Boolean option that specifies that all message types are to be deleted. The use of the `-all` option is mutually exclusive to the specification of the `-error`, `-warning`, and `-info` options. When none of the four options is specified, `-all` is assumed.
- `-error`
An optional Boolean option that specifies that the messages to be deleted are of type error. The use of the `-error` option is mutually exclusive to the specification of the `-all`, `-warning`, and `-info` options. When none of the `-error`, `-warning` and `-info` options is specified, `-all` is assumed.
- `-warning`
An optional Boolean option that specifies that the messages to be deleted are of type warning. The use of the `-error` option is mutually exclusive to the specification of the `-error`, `-warning`, and `-info` options. When none of the `-error`, `-warning` and `-info` options is specified, `-all` is assumed.

- **-info**
An optional Boolean option that specifies that the messages to be deleted are of type info. The use of the **-error** option is mutually exclusive to the specification of the **-all** option. When none of the **-error**, **-warning** and **-info** options is specified, **-all** is assumed.
- **-silent**
An optional Boolean option that turns off the warning that is normally generated if the specified configuration element does not contain any messages of the specified type.

Examples

The following example deletes all message on and below the wrapper `DftSpecification(moda,rtl)`. The addition and deletion of messages on the [DftSpecification](#) and [DefaultsSpecification/DftSpecification](#) wrappers is automatically handled by the [process_dft_specification](#) command.

```
delete_config_messages DftSpecification(moda,rtl) -hierarchical
```

Related Topics

[add_config_message](#)
[get_config_messages](#)

delete_config_tabs

Context: all contexts

Mode: all modes

Deletes one or many configuration tree tabs from the Configuration Data Visualizer window that was previously added using the `add_config_tab` or `display_specification` command.

Usage

```
delete_config_tabs [config_object_spec] [-silent]
```

Description

Deletes one or many configuration tree tabs from the Configuration Data Visualizer window that was previously added using the [add_config_tab](#) or [display_specification](#) command.

When no `config_object_spec` value is specified then all existing tabs are deleted.

Arguments

- *config_object_spec*
An optional value that specifies one or more configuration wrappers. The value is either the a Tcl list of one or more names of wrappers or a collection containing one or more configuration wrappers. The wrappers are the root wrapper displayed in the tab.
- `-silent`
An optional value that turns off the warning that is normally generated when *config_object_spec* contains a configuration element that is not a root wrapper displayed in an existing tab or when no configuration tab exists at all.

Examples

The first example deletes the tab in which the `DftSpecification(mod1.rtl)` wrapper is displayed. The second example deletes all tabs and suppresses the warning that would be generated if there are no tab to delete.

```
delete_config_tabs DftSpecification(mod1.rtl)  
delete_config_tabs -silent
```

Related Topics

[add_config_tab](#)

[display_specification](#)

delete_connections

Context: all contexts

Mode: insertion

Disconnects net, pin, or port objects.

Usage

delete_connections *obj_spec* [-within] [-silent]

Description

If the disconnected object is a pin, the pin is left without a connection in the instance independent of whether the pin is an input, output, or inout pin. If the object is a port, if the associated net of the same name is connected to any other object, the tool creates a uniquified net and uses it in all of the connections the original net made. This results in input and inout ports with no fanout, and output and inout ports with no fanin. If the object is a net that is also a pin, the tool creates a uniquified net and uses it in all of the connections the original net made. This results in input and inout pins with no fanout, and output and inout ports with no fanin.

You must be careful when using the delete_connection command inside a non-uniquified design. You must only do the move or disconnection once per module and once per generate loop count. To perform this robustly, see how the parent_instance and the leaf_name_hash attributes are used in Section 3 of “[Example 5](#)” on page 923 in the [get_dft_cell](#) command description.

Arguments

- *obj_spec*

The *obj_spec* must be a Tcl list of one or more net, pin, or port names, or a collection of one or more net, pin or port names created by the `get_nets`, `get_pins`, or `get_ports` commands.

If an object within *obj_spec* does not exist and the `-silent` option is specified, the object is ignored. If an object within *obj_spec* does not exist and the `-silent` option is not specified, the tool generates an error.

- `-within`

An optional argument that specifies to disconnect a pin inside the boundary of a hierarchical instance. That is, the tool disconnects the pin from the net to which it is attached inside the instance. If you do not use this argument, the tool disconnects the pin on the outside of the instance. This argument requires that *obj_spec* is a pin on a hierarchical instance.

- `-silent`

An optional argument that specifies to ignore specified objects that do not exist and to not generate error messages.

Examples

Example 1

The following example disconnects the net or constant that may be connected to input pin u1/A.

```
delete_connections u1/A  
{ }
```

Example 2

The following example disconnects the net or constant that may be connected to the pin within the generated collection.

```
delete_connections [get_pins ABC*/TE]  
{ }
```

Example 3

The following example disconnects the internal fanout of the input pin ABC/in1. It does that by renaming the net ABC/in1 to ABC/in1_ts1. The pin ABC/in1 ends up with no fanout.

```
delete_connections [get_nets ABC/in1]  
{ABC/in1_ts1}
```

Example 4

The following example disconnects the internal fanin of the output port out1. It does that by renaming the net out1 to out1_ts1. The port out1 ends up with no fanin.

```
delete_connections out1  
{out_ts1}
```

delete_core_descriptions

Context: all contexts

Mode: setup

Removes core descriptions that have been read in using the `read_core_descriptions` command from memory.

Usage

```
delete_core_descriptions {-all | -cores core_name_list} [-modes mode_name_list]
```

Description

Removes core descriptions that have been read in using the `read_core_descriptions` command from memory.

You cannot delete a core description that is instantiated in another core description unless you specify to delete the parent core description also, by using the `-all` switch for example.

If a corresponding core instance exists for the core description, this command deletes the core instance along with the core description.

If you specify to delete multiple descriptions, and deleting one or more core descriptions fails, the command continues deleting the remaining core descriptions.

You can delete a top-level core description only in a flow without a top-level netlist. For information about such a flow, see “[Retargeting Patterns Without a Top-Level Netlist](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **-all**
A switch that specifies to delete all core description files in the current design.
- **-cores *core_name_list***
A required switch and Tcl list that specifies the core names of the core descriptions to be deleted.
- **-modes *mode_name_list***
An optional switch that specifies the mode of the core to delete.

Examples

The following example reads in the core descriptions from the `top_core_des` file and then reports the defined core descriptions. The top-level core description is then deleted from memory. The `second_level_core` becomes the top of the design. The `report_core_descriptions` command then reports the defined core descriptions after the top-level core description is deleted.

set_context patterns -scan_retargeting
read_core_descriptions top_core_des

delete_core_instances

Context: patterns -scan, patterns -scan_retargeting

Mode: setup

Removes an instance binding created with the `add_core_instances` command.

Usage

```
delete_core_instances
  {-all | -cores core_names | -modules module_objects | -instances instance_objects
  | -current_design}
  [-modes mode_names] [-silent]
```

Description

Removes an instance binding created with the [add_core_instances](#) command.

You can use this command to retarget patterns for different configurations sequentially in the same tool session. After completing one configuration and before switching to the next configuration, you use the `delete_core_instances` command to delete the old core instances so that the core instances used in the next session can be added.

Arguments

- **-all**
A required switch that specifies to remove all bindings that have been added with the [add_core_instances](#) command.
- **-cores *core_names***
A required switch and Tcl list that specifies the core names of the core descriptions from which all instance bindings should be removed.
- **-modules *module_objects***
A required switch and string pair that specifies a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects. This command removes the instance bindings for each instantiation of those modules in the design.
- **-instances *instance_objects***
A required switch and string pair that specifies a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects. This command removes the instance bindings for each instance in the list.
- **-current_design**
A required switch that specifies to delete the core instance with respect to the current design. This switch is mutually exclusive with the `-core`, `-modules`, and `-instances` switches.

- `-modes mode_names`
An optional switch and string pair that specifies the list of modes to delete for each specified core instance.
- `-silent`
An optional switch that specifies to suppress warning messages.

Examples

Example 1

The following example adds the same instance twice. The second attempt fails with a warning, deletes it, and re-adds it successfully.

```
add_core_instances -instances core_1 -cores my_core  
// Added core instance 'core_1'.  
  
add_core_instances -instances core_1 -cores my_core  
// Warning: Instance 'core_1' has already been added. Skipping.  
  
delete_core_instances -instances core_1  
add_core_instances -instances core_1 -cores my_core  
// Added core instance 'core_1'.
```

Example 2

The following example adds two instances of the same module and then deletes both of them.

```
add_core_instances -instances {core_1 core_2} -cores my_core  
// Added core instance 'core_1'.  
// Added core instance 'core_2'.  
  
delete_core_instances -instances {core_1 core_2}
```

Example 3

The following example adds two instances and then attempts to delete the two instances as well as one other instance that has not been added. The `-silent` usage suppresses the warning messages that would be printed for the three non-existing core instances.

```
add_core_instances -instances {core_1 core_2} -cores my_core  
delete_core_instances -instances {core_1 core_2 core_3}  
  
// Warning: Instance 'core_3' of module 'my_core_2' has not been added as  
// a core instance. Skipping.  
  
delete_core_instances -instances {core_1 core_2 core_3} -silent
```

Example 4

The following example adds two instances of the same module and then deletes both of them through the module.

add_core_instances -instances {core_1 core_2} -cores my_core

```
// Added core instance 'core_1'.  
// Added core instance 'core_2'.
```

delete_core_instances -modules my_module

delete_design

Context: all contexts

Mode: setup

Removes all design modules including the flat model and all tool data that is design-specific.

Usage

`delete_design`

Description

Cell modules read in with the [read_cell_library](#) command are preserved. However, cell modules that are Verilog modules surrounded by ``celldefine` and loaded with the [read_verilog](#) command are also deleted.

This command also clears any Tessent Visualizer schematic or instance browser tabs. Note that this command does not delete cell libraries unless a flat model is deleted.

When the `delete_design` command is deleting a flat model, and that flat model was saved with a list of enabled and turned off commands, then the restriction on the turned off commands is removed. In other words, all commands permitted in the tool are enabled for the next design.

Arguments

None

Examples

The following example removes all design modules:

```
delete_design
```

delete_dfm

Context: patterns -scan_diagnosis

Mode: analysis

Deletes a DFM rule from the open LDB.

Usage

```
delete_dfm [-rule rule_name] | [-vacuum]
```

Description

Deletes a DFM rule from the open LDB.

The -rule and -vacuum options are mutually exclusive.

Arguments

- -rule *rule_name*

An optional switch that specifies a specific DFM rule to delete from the LDB. The rule name is one of the rule names as reported by the report_dfm_rules command. Enclose the rule name in quote marks.

When not specified, the tool deletes all the DFM rules from the open LDB.

- -vacuum

An optional switch that specifies to vacuum the LDB to reduce its size on disk. The tool recreates the LDB, moving records around to squeeze out any holes left after deleting DFM rules. For large databases, this operation may take a long time.

Examples

Example 1

The following example shows the DFM rules before and after deleting one rule from the LDB.

```
report_dfm_rules
```

```
delete_dfm -rule "metal_cross_edge_route1"
```

id	rule	layer	type
1	minimum_space_4_line_route1	route_1	BRIDGE
2	metal_cross_edge_route1	route_1	OPEN
3	low_density_min_space_route2	route_2	BRIDGE
4	half_comb_route3	route_2	OPEN
5	metal_cross_edge_route1	route_3	OPEN
6	corner_to_interior_metal4	route_4	BRIDGE
7	divergent_line_with_jog_metal5	route_5	BRIDGE
8	metal_cross_edge_route1	route_5	OPEN
9	route_5_barbell	route_5	OPEN
10	route_2_between_vias	route_2	OPEN

report_dfm_rules

id	rule	layer	type
1	minimum_space_4_line_route1	route_1	BRIDGE
3	low_density_min_space_route2	route_2	BRIDGE
4	half_comb_route3	route_2	OPEN
6	corner_to_interior_metal4	route_4	BRIDGE
7	divergent_line_with_jog_metal5	route_5	BRIDGE
9	route_5_barbell	route_5	OPEN
10	route_2_between_vias	route_2	OPEN

Example 2

The following example deletes multiple DFM rules. It shows you three ways you can specify deleting rules.

```
delete_dfm -rule "rule_name1 rule_name2"
```

or:

```
delete_dfm -rule "rule_name1" "rule_name2"
```

or:

```
delete_dfm -rule "rule_name1"
```

```
delete_dfm -rule "rule_name2"
```

delete_dft_clock_enables

Context: dft (with no sub context)

Mode: setup

Prerequisites: The current design must be set with the `set_current_design` command.

Deletes one or all previously added DFT clock enable signals.

Usage

```
delete_dft_clock_enables port_pin_spec | -all
```

Description

All DFT clock enable signals are automatically deleted when elaborating a new design or re-elaborating the same design using the `set_current_design` command.

Arguments

- ***port_pin_spec***
A required string that specifies the name of a port or pin on the current design, or a collection containing a port or pin on the current design, or a port on a sub-module. The pin or ports must have previously been the target of an [add_dft_clock_enables](#) command.
- **-all**
A required Boolean switch that specifies that all pins and ports that were previously the target of an [add_dft_clock_enables](#) command are to be removed from the DFT clock enable signal list.

Examples

The following example adds three DFT clock enable signals, reports them, deletes one and reports them again, deletes them all and finishes with a last report. Notice that the clock enable signal defined on the port “FE” of the cell “cgand” remains even after deleting them all because this one was not defined with the `add_dft_clock_enables` command but instead was defined in the Tessent cell library.

```
add_dft_clock_enables en  
add_dft_clock_enables blockb_i1/en2 -active_polarity 0  
report_dft_clock_enables  
  
// Dft clock enables

delete_dft_clock_muxes

Context: dft (with no sub context)

Mode: setup

Prerequisites: The current design must be set with the `set_current_design` command.

Deletes one or all previously added DFT clock multiplexers.

Usage

```
delete_dft_clock_muxes pin_port_spec | -all
```

Description

All DFT clock mux specifications are automatically deleted when elaborating a new design or re-elaborating the same design using the `set_current_design` command.

Arguments

- *port_pin_spec*
A required string that specifies the name of a port or pin on the current design, or a collection containing a port or pin on the current design. The pin or port must have previously been the target of an `add_dft_clock_mux` command.
- **-all**
A required Boolean switch that specifies that all pins and ports that were previously the target of an `add_dft_clock_mux` command are to be removed from the DFT clock mux list.

Examples

The following example adds three DFT clock multiplexers, reports them, deletes one and reports them, deletes them all and then reports them again.

```
add_dft_clock_muxes clkb -test_clock_source mem1/clock -dft_signal_source_name all_test
register_static_dft_signal_names pll_bypass
add_dft_clock_muxes pll1/vco -test_clock_source pll1/ref \
  -dft_signal_source_name pll_bypass

delete_dft_control_points

Context: dft (with no sub context)

Mode: setup

Prerequisites: The current design must be set with the `set_current_design` command.

Deletes one or all previously added DFT control points.

Usage

```
delete_dft_control_points pin_port_spec | -all
```

Description

All DFT control point specifications are automatically deleted when elaborating a new design or re-elaborating the same design using the `set_current_design` command.

Arguments

- ***port_pin_spec***
A required string that specifies the name of a port or a pin on the current design or a collection containing a port or a pin on the current design. The pin or port must have previously been the target of an `add_dft_control_points` command.
- **-all**
An optional Boolean switch that specifies that all pins and ports that were previously the target of an `add_dft_control_points` command are to be removed from the DFT control point list.

Examples

The following example adds three DFT control points, reports them, deletes one and reports them, and then deletes them all and reports them again.

```
add_dft_control_points portb -dft_signal_source_name all_test  
register_static_dft_signal_names pll_bypass  
add_dft_control_points pll1_mux/s -dft_signal_source_name pll_bypass

delete_dft_modal_connections

Context: dft (with no sub context)

Mode: setup

Prerequisites: The current design must be set with the `set_current_design` command.

You use the `delete_dft_modal_connections` command to delete modal connection specifications previously added by the `add_dft_modal_connections` command.

Usage

```
delete_dft_modal_connections  
  {-ports port_spec | -auxiliary_data_pins pin_spec | -all}
```

Description

The `delete_dft_modal_connections` command is used to delete modal connection specifications previously added by the `add_dft_modal_connections` command. You can either delete all previously defined DFT modal connections using the `-all` switch or delete all connections to or from a set of ports or auxiliary data pins using the `-ports` or `-auxiliary_data_pins` switch. Use the `report_dft_modal_connections` command to see the list of ports or auxiliary data pins that can be referenced.

Arguments

- **-ports *port_spec***
A switch used to specify a list of one or more port names or a collection containing one or more port objects. The ports must have been previously referenced using the “`add_dft_modal_connections -ports`” command.
- **-auxiliary_data_pins *pin_spec***
A switch used to specify a list of one or more pin names or a collection containing one or more pin objects. The pins must have been previously referenced using the “`add_dft_modal_connections -auxiliary_data_pins`” command. An auxiliary data pin automatically inferred using the “`add_dft_modal_connections -auxiliary_data_pins`” command can also be referenced. The “Modes:” section of the report created with the `report_dft_modal_connections` command is useful to see all the port and auxiliary pins scheduled to be part of a modal connection.
- **-all**
A Boolean switch used to specify that all previously specified DFT modal connections are to be deleted.

Examples

The following example shows the result of the `report_dft_modal_connections` before and after a `delete_dft_modal_connections` command invocation. The starting configuration comes from [Example 1](#) of the `add_dft_modal_connections` command description.

SETUP> report_dft_modal_connections

delete_dft_signals

Context: dft

Mode: setup

Deletes a DFT signal that was previously added using the `add_dft_signals` command.

Usage

```
delete_dft_signals {name ...} | -all_user_added [-silent]
```

Description

A command used to delete a DFT signal that was previously added using the [add_dft_signals](#) command. Only DFT signals that were added and not yet created can be deleted. Once a DFT signal is inserted using the [process_dft_specification](#) command, the signal exists and can no longer be deleted.

Arguments

- *name*
A repeatable string defining one or more DFT signal names to delete. You can specify several names in one command line invocation. You can also supply several names in a single well formatted Tcl list.
- **-all_user_added** [-silent]
A Boolean switch that specifies the deletion of all DFT signals that were previously added using the [add_dft_signals](#) command.

The `-silent` optional argument specifies not to generate error and status messages when DFT signals cannot be found, or the deletion is not possible.

Examples

The following example shows how to delete one DFT signal at a time or all of them at one time:

```
add_dft_signals ltest_en int_ltest_en ext_ltest_en
```

```
get_dft_signals -list
```

```
ltest_en int_ltest_en ext_ltest_en
```

```
delete_dft_signals ltest_en
```

```
get_dft_signals -list
```

```
int_ltest_en ext_ltest_en
```

```
delete_dft_signals -all_user_added
```

```
get_dft_signals -list
```

delete_edt_blocks

Context: `dft -edt`, `patterns -scan (EDT On)`, `patterns -scan_diagnosis`

Mode: `setup`

Removes the data for the specified EDT block(s) from the tool's internal database.

Usage

`delete_edt_blocks -All | block_name`

Description

The `delete_edt_blocks` command removes all data for the specified EDT block(s) from the tool's internal database, making the block(s) unavailable for use with the [set_current_edt_block](#) command.

If you delete the current EDT block, leaving just one remaining EDT block defined, the tool automatically sets the EDT context to the remaining block. The tool does not reset the EDT context, however, if there is more than one defined EDT block remaining; in this case, subsequent context-sensitive commands that define attributes for a given EDT block return an error until you set the EDT context using the [add_edt_blocks](#) or `set_current_edt_block` command.

You set or change the EDT context when you restrict the applicability of certain commands to a particular EDT block by issuing the `add_edt_blocks` or [set_current_edt_block](#) command. The EDT block on which context-sensitive commands currently operate is referred to as the current EDT block. The current EDT block remains the sole target of the context-sensitive commands until you delete its definition using the `delete_edt_blocks` command or change the context to a different EDT block using the `add_edt_blocks` or [set_current_edt_block](#) command. The `add_scan_chains` command, EDT-specific commands that define attributes for a given block, and some reporting commands are presently the only context-sensitive commands. Most commands like `set_system_mode`, `report_statistics` and `create_patterns`, are unaffected by the EDT context and always operate on the whole design.

Arguments

- **-All**
A switch that specifies to remove the data for all EDT blocks from the tool's internal database.
- ***block_name***
A string that specifies to remove the data for a particular EDT block from the tool's internal database.

Examples

Example 1

The following example displays currently defined EDT block names, then removes the definition for the one representing the current EDT block.

```
report_edt_blocks  
  
// my_core1_block  
// my_core3_block (current block)  
  
delete_edt_blocks my_core3_block  
report_edt_blocks  
  
// Block deleted. my_core1_block is now the current EDT block.
```

Example 2

The following example shows how the tool manages the current EDT context when there are more than two blocks defined.

```
report_edt_blocks  
  
// my_core1_block  
// my_core2_block  
// my_core3_block  
// my_core4_block (current block)  
  
delete_edt_blocks my_core3_block  
report_edt_blocks  
  
// my_core1_block  
// my_core2_block  
// my_core4_block (current block)  
  
delete_edt_blocks my_core4_block  
  
// Block deleted. No EDT block now selected as current block.  
  
set_edt_options -channels 4  
  
// Error: No current EDT block defined.  
  
set_current_edt_block my_core2_block  
set_edt_options -channels 4  
report_edt_configuration
```

delete_edt_blocks

```
//  
// EDT block "my_core2_block"  
// -----  
// IP version:                3  
// External scan channels:    4  
// Bypass logic:              On  
// Lockup cells:              On  
// Clocking:                  edge-sensitive  
//  
// Note: Only current EDT block "my_core2_block" is reported. Use "report  
// edt configuration -all_blocks" to report the configurations of all  
// blocks.
```

Related Topics

[add_edt_blocks](#)

[report_edt_blocks](#)

[set_current_edt_block](#)

delete_edt_configurations

Context: dft -edt

Mode: setup

Prerequisites: One or more compression configurations must be defined with the [add_edt_configurations](#) command.

Deletes specified compression configurations from all blocks in a design.

Usage

```
delete_edt_configurations -All | config_name
```

Description

In a multi-block design flow, all subsequently added blocks inherit the defined compression configurations. The compression configuration parameters are then set for each block context.

Arguments

- **-All**
A required switch that deletes all the compression configurations from all the blocks of the design.
- ***config_name***
A required string that specifies the name of a single compression configuration to delete from all the blocks of the design.

Examples

The following example reports the currently defined compression configurations in a design, deletes one, and reports the remaining compression configurations.

report_edt_configuration

```
// my_core1_block
// IP version:           1
// Bypass logic:         On
// Lockup cells:         On
// Clocking:              edge-sensitive
// Input channels:       [manufacturing_test : 10] [system_test : 4]
// Output channels:      [manufacturing_test : 5] [system_test : 2]
// Bypass chains: 5
```

```
delete_edt_configurations system_test
report_edt_configuration
```

```
// my_core1_block
// IP version:          1
// Bypass logic:       On
// Lockup cells:       On
// Clocking:           edge-sensitive
// Input channels: [manufacturing_test : 10]
// Output channels: [manufacturing_test : 5]
// Bypass chains: 5
```

delete_false_paths

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Removes definitions of false paths.

Usage

```
delete_false_paths [-All] [-Verbose]
  [-From source_node... | -FROM_Clock clock_signal_name...]
  [-TO sink_node... | -TO_Clock clock_signal_name...]
  [{-THrough through_node... }...]
```

Description

The `delete_false_paths` command deletes from the tool's internal database, false paths you defined using the `add_false_paths` command.

Arguments

Tip

 When using the following arguments, you can include any number of asterisks (*) in pin or instance pathnames. The command treats an asterisk as a wildcard character, enabling you to use it to match many pathnames in the design.

- **-All**
An optional switch that specifies to delete all previously defined false paths.
- **-Verbose**
An optional switch that directs the tool to display the definition of each deleted false path as it is deleted.
- **-From *source_node*...**
An optional switch and repeatable string pair that specifies the starting point of a false path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the output pins of the instance to be starting points. For a clock PI, the tool considers the outputs of all the non-transparent latches, flip-flops and RAMs associated with the clock PI to be starting points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

If a specified source node does not translate to an internal gate, the tool transcripts an error message and does not delete the false path definition.

- **-FROM_Clock** *clock_signal_name...*

An optional switch and repeatable string pair that specifies the starting point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of a clock signal and considers the outputs of all non-transparent latches, flip-flops and RAMs associated with this clock signal to be starting points.

If a specified clock signal name does not translate to an internal gate, the tool transcripts an error message and does not delete the false path definition.

- **-TO** *sink_node...*

An optional switch and repeatable string pair that specifies the end point of a false path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the input pins of the instance to be end points. For a clock PI, the tool considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with the clock PI to be end points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

If a specified sink node does not translate to an internal gate, the tool transcripts an error message and does not delete the false path definition.

Note

 For two port latches with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “delete_false_paths... -to CLK2” would delete false paths that have an end point at D2.

- **-TO_Clock** *clock_signal_name...*

An optional switch and repeatable string pair that specifies the end point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of an internal clock signal and considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with this clock to be end points.

If a specified clock signal name does not translate to an internal gate, the tool transcripts an error message and does not delete the false path definition.

- **{-THrough** *through_node...}*...

An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the false path must pass. A valid through node is a pin or instance pathname. Clock PIs are not supported as through nodes and the tool makes no attempt to determine if a pin pathname is that of an internal clock pin.

When you use multiple -Through arguments, the tool considers their order left-to-right in the command string to be the order in which a signal would pass through the nodes on the specified false path. For example, the following false path specification:

```
delete_false_paths -from A -through B C -through D E -to F
```

specifies all paths that start from A, pass through either B or C, then pass through D or E, and end at F. If you do not use the `-Through` argument when specifying a path, the tool considers all paths from the specified starting points to the specified end points to be false paths.

If a through node does not translate to an internal gate, the tool transcripts an error message and does not delete the false path definition.

Examples

The following example displays current false path definitions, then deletes one of them, echoing its definition as it is deleted:

report_false_paths -all

```
// False Path -from /my_design/a /my_design/b -through /my_design/u1
// False Path -to /my_design/c
// False Path -through /my_design/u24 /my_design/u25
// Total reported paths = 3
```

delete_false_paths -verbose -to /my_design/c

```
// Deleting false paths ...
// False Path -to /my_design/c ( /my_design/c/Y (36) )
// Deleted 1 false paths.
```

Refer to the [add_false_paths](#) command for examples of signal matches for pathnames specified using the asterisk (*) character.

delete_fault_sites

Context: dft -edt, patterns -scan

Mode: analysis

Removes bridge entries, delay paths, user-defined fault sites, and any associated faults from the current fault list. For UDFMs, all faults are removed.

Usage

Bridge Faults Usage

```
delete_fault_sites {-All | {bridge_name... -NAME}}
```

Path Delay Faults Usage

```
delete_fault_sites {-All | -Unsensitizable_paths | path_name...}
```

UDFM Faults Usage

```
delete_fault_sites {-All | filename}
```

Description

Depending on the current fault model, deletes specified fault sites (bridge entries or delay paths) from the current fault list. The `delete_fault_sites` command removes faults loaded with the `read_fault_sites` command. When a fault site is removed from the current fault list, the associated patterns are also removed from the internal pattern set.

For more information on bridge faults and the bridge fault definition file, refer to “[The Static Bridge Fault Model](#)” in the *Tessent Scan and ATPG User’s Manual*.

For more information on path delay faults and the path definition file, refer to “[Path Delay Test Set Creation](#)” in the *Tessent Scan and ATPG User’s Manual*.

For more information on UDFMs, see “[About User-Defined Fault Modeling](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **-All**
A switch that specifies to remove all fault sites from the current fault list and deletes all faults associated with the deleted fault sites.
- ***bridge_name***
A repeatable string that specifies a bridge name.
- **-NAME**
A switch that specifies the argument strings preceding the switch are bridge names. This switch is required just once, whether you enter one or multiple ***bridge_name*** strings.

- **-Unsensitizable_paths**

A switch that directs the tool to perform an ATPG analysis of each path, and to delete those proved unsensitizable. For a list of critical paths identified by static timing analysis, for example, use this switch to identify and delete the unsensitizable paths.

Note

 This ATPG process may be very lengthy. A progress message is displayed after every 100 paths analyzed, as well as at the end of the analysis.

- ***path_name***

A repeatable string that specifies the name of an existing path that resides in the current path definition file and whose path delay faults you want to remove from the current path delay fault list.

- ***filename***

A required string that specifies a UDFM filename. Use this option to delete all fault sites associated with a specified UDFM file.

Examples

Example 1

The following example reads the bridge information in the bridge fault definition file */user/design/bridgefile*, then deletes two of the three valid entries added to the fault site list:

```
set_fault_type bridge  
read_fault_sites /user/design/bridgefile  
  
//  
// Load bridge entries from file "/user/design/bridgefile".  
//  
// 5 bridge entries were read from file "/user/design/bridgefile".  
// 2 bridge entries were skipped due to unknown net name.  
// 3 bridge entries were added to the fault site list.  
  
report_fault_sites
```

delete_fault_sites

```

BRIDGE "U7.BRIDGE" {
  NET1 = "/G5";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}
BRIDGE "U5.BRIDGE" {
  NET1 = "/G4";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}
BRIDGE "U0.BRIDGE" {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}

```

**delete_fault_sites U5.BRIDGE U7.BRIDGE -name
report_fault_sites**

```

BRIDGE "U0.BRIDGE" {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}

```

Example 2

The following path delay example reads the path information from the file, */user/design/pathfile*, and deletes one of the two paths:

**set_fault_type path_delay
read_fault_sites /user/design/pathfile
report_fault_sites**

```

PATH "path0" =
  PIN /I$6/Q + ;
  PIN /I$35/B0 + ;
  PIN /I$35/C0 + ;
  PIN /I$1/I$650/IN + ;
  PIN /I$1/I$650/OUT - ;
  PIN /A_EQ_B + ;
END ;
PATH "path1" =
  PIN /I$6/Q + ;
  PIN /I$35/B1 + ;
  PIN /I$35/C1 + ;
  PIN /I$1/I$649/IN + ;
  PIN /I$1/I$649/OUT - ;
  PIN /I$5/D - ;
END ;

```

**delete_fault_sites path0
report_fault_sites**

```
PATH "path1" =  
  PIN /I$6/Q + ;  
  PIN /I$35/B1 + ;  
  PIN /I$35/C1 + ;  
  PIN /I$1/I$649/IN + ;  
  PIN /I$1/I$649/OUT - ;  
  PIN /I$5/D - ;  
END ;
```

Example 3

The following example deletes all fault sites associated with the *c090_std.udfm* UDFM model:

```
delete_fault_sites /home/design/c090_std/c090_std.udfm
```

Example 4

The following example deletes all fault sites from the current fault list:

```
delete_fault_sites -All
```

delete_faults

Context: dft -edt, dft -test_points, patterns -scan

Mode: analysis

Removes faults from the current fault list.

Usage

```
delete_faults fault_model_specific_options [power_aware_options] [ -KEEP_Patterns ]  
    [{> | >> } file_pathname]
```

Stuck/Transition/Toggle/Iddq Faults Usage

```
[-All | {-Class {class_name | class_code} ... }  
  | {object_expression ... [-PIn | -Instance | -MODule [-PIN module_pin_pathname ... ]}]  
  | {-CLOCK_Domains {ALL | clock_pathname ... } [-NO_EQUivalent_clocks]  
  | -EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains}  
  | {-CAPture_procedures {ALL | capture_procedure_name ... } }  
  | {[-SCAN_Enable] [-CLOCK_Cones] [-IO] [-ASYNchronous_controls]}  
  [-Stuck_at {01 | 0 | 1}]  
  [-FRom pin ... ] [-THrough pin ... ] [-TO pin ... ]  
  [-STOP_at {SEQUential_elements | SCAN_cells | PORTs_only}  
  [-fanout_off_path_stop {on | off } ] [-fanin_off_path_stop { on | off } ]  
  [-VERbose]
```

UDFM Fault Usage

```
{-All | {-Class {class_name | class_code} ... }  
  | {object_expression ... [-INstance]}  
  | {-CLOCK_Domains {ALL | clock_pathname ... } [-NO_EQUivalent_clocks]  
  | -EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains}  
  | {[-SCAN_Enable] [-CLOCK_Cones] [-IO] [-ASYNchronous_controls]}  
  | -SCAN_Data  
  | {[-UDFM_type name] [-CELLname] [-MODule name] [-FAULT name]}  
  [-FRom pin ... ] [-THrough pin ... ] [-TO pin ... ]  
  [-STOP_at {SEQUential_elements | SCAN_cells | PORTs_only}  
  [-fanout_off_path_stop {on | off } ] [-fanin_off_path_stop { on | off } ]  
  [-VERBoSe]
```

Bridge Fault Usage

```
[-All | {-Class {class_name | class_code} ... }  
  | {{bridge_name ... -NAME} | {net_pathname ... -SINGle} | {instance_name ... -SINGle}}  
  | {-CLOCK_Domains {ALL | clock_pathname ... } [-NO_EQUivalent_clocks]  
  | -EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains}  
  | {-CAPture_procedures {ALL | capture_proc_name ... } }  
  | {[-SCAN_Enable] [-CLOCK_Cones] [-IO] [-ASYNchronous_controls]}]
```

Path Delay Faults Usage

```
[-All | name_of_delay_path... | -Class {class_name | class_code}...]
  [-Both | -Rise | -Fall] [-UNTestable]
```

Power-Aware Options (applicable only after you have loaded CPF/UPF power data)

```
[-ON_domains | -OFF_domains | {-POWER_domains {domain_name ...}}]
  [-ISolation_cells] [-LEvel_shifters] [-REtention_cells]
```

Description

The `delete_faults` command deletes faults you added using the `add_faults` or `read_faults` command from the fault list. The power-aware options remove faults based on power domains and power features after you have loaded a CPF or UPF file.

Alternatively, you can also delete a large number of faults using the `-delete` switch of the [read_faults](#) command.

When you run this command, the tool discards all patterns in the current test pattern set by default. To save the current test patterns, you must explicitly write them with the [write_patterns](#) command before using the `delete_faults` command or use the `-keep_patterns` switch.

By default, the `delete_faults` command ignores the constraint values implied in the data path when deleting faults in the data path. However, the tool still considers the constraint values for clock path faults.

You cannot use a single command to `delete_faults` for clock domains, capture procedures, and specific classes, objects, or paths. Use a separate command instance for each.

When you delete bridge faults, the currently loaded faults sites remain intact.

Arguments

- **-KEEP_Patterns**
An optional switch that specifies that the tool preserves the current test patterns while deleting faults. The default behavior is for the tool to delete the current test patterns as faults are deleted.
- **-All**
A required switch that deletes all faults in the current fault list.
- ***name_of_delay_path***
A required, repeatable string that specifies the name of the delay path to delete from the current fault list. The name must correspond to the name of a delay path defined in [the path definition file](#).
- **-Class {*class_name* | *class_code*}...**
A required switch and repeatable literal pair that deletes one or more classes of faults. The table below lists the valid fault *class_codes* and their associated fault *class_names*.

Table 3-21. Fault Class Codes and Class Names

Fault Class Codes	Fault Class Names	Fault Class Coverage
FU	Full	TE+UT
TE	TEstable	DT+PD+AU+UD
DT	DETEcted	DS+DI+DR
DS	DET_Simulation	
DI	DET_Implication	
DR	DET_Robust (Path Delay Testing only)	
DF	DET_Functional (Path Delay Testing only)	
PD	POSDET	PT+PU
PU	POSDET_Untestable	
PT	POSDET_Testable	
AU	Atpg_untestable	
UD	UNDEtected	UC+UO
UC	UNControlled	
UO	UNObserved	
UT	UNTestable	UU+TI+BL+RE
UU	UNUsed	
TI	TIed	
BL	Blocked	
RE	Redundant	

- - Both | -Rise | -Fall

An optional switch that specifies which faults to delete for each path already added via the [read_fault_sites](#) command. These switches are valid only for path delay faults.

-Both — Deletes both the slow-to-rise and slow-to-fall faults. This is the default.

-Rise — Deletes only the slow-to-rise faults.

-Fall — Deletes only the slow-to-fall faults.

- *object_expression*

A required string representing a list of instances or pins associated with the faults you want to delete from the current fault list. In the case of UDFM, you can specify only instances. You can use any number of asterisk (*) and question mark (?) wildcard characters.

Instance pathnames must be Tessent Cell library cell instances. Pin pathnames must be Tessent Cell library cell instance pins, also referred to as design level pins. If the object

expression specifies a pin within an instance of a Tessent Cell library model, the tool ignores it. By default, the tool matches pin pathnames first. If it does not find a pin pathname match, the tool next tries to match instance pathnames. Force the tool to match only pin pathnames or only instance pathnames by including the `-Pin` or `-Instance` switch after the *object_expression*.

- **-PIN**
An optional switch that uses the *object_expression* to match only pin pathnames and then delete the associated faults.
- **-Instance**
An optional switch that uses the *object_expression* to match only instances and then delete the associated faults.
- **-Module [-PIN *module_pin_pathname* ...]** (Stuck/Transition/Toggle/Iddq only)
A switch that interprets the *object_expression* argument as a module pathname. All instances of the module are affected. You can use the asterisk (*) and question mark (?) wildcards for the *object_expression* argument, and the tool adds the faults for all matching modules or library models.

When you follow the `-Module` switch with the optional `-PIN` switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given *object_expression* and deletes faults for every pin specified in *module_pin_pathname* list.
- **-Untestable**
An optional switch that deletes all identified, untestable path delay faults. Untestable faults are common when using random patterns. This includes faults that the tool cannot detect due either to constraints or the use of a single capture clock.
- ***bridge_name***
A required, repeatable string that specifies the name of a bridge. The tool deletes the faults associated with the specified bridge from the current fault list.
- ***net_pathname***
A required, repeatable string that specifies the name of a single net. The tool deletes the faults associated with the specified net from the current fault list.
- ***instance_name***
A required, repeatable string that specifies the name of an instance. The tool deletes the faults associated with the specified instance from the current fault list.
- **-NAME**
An optional switch specifying that all entered strings are bridge names.

- **-SINGLE**

An optional switch specifying that all the entered strings are either a single net or instance. The tool searches for a net first. If it cannot find a corresponding net, the tool searches for a corresponding instance.

If the string specifies a net, the tool deletes each bridge entry associated with the net.

If the string specifies an instance that contains a non-dominant net included in a bridge entry, the tool deletes the associated faults.

- **-CLOCK_Domains** {**ALL** | *clock_pathname...*}

A required switch and literal or repeatable string pair that specifies a list of clocks that the tool uses to decide the faults to add to the fault list, given the following requirements:

- **Static Faults** — The tool adds a fault to the fault list if it can be captured by any clock in the specified list of clocks or any of its equivalent clocks.
- **Transition Faults** — The tool adds a fault to the fault list if one of the following is true:
 - i. The launch and capture clock are the same clock from the specified list of clocks
 - ii. The launch and capture clock are synchronous clocks from the specified list of clocks
 - iii. The launch or capture clock from the specified are equivalent clocks

When you use this switch, the tool ignores the constraint values implied in the data path when adding faults in the data path. However, the tool still considers the constraint value for the clock cone tracing to determine the state element clock domain.

ALL — A literal that specifies all the clocks in the design.

clock_pathname — A repeatable string that specifies a particular clock.

The tool deletes faults potentially detectable by a clock that you specify with this switch, even if they might also be detectable by an unspecified clock.

The tool takes user-defined non-race clocks and faults between synchronous clock groups into account when adding or deleting faults by clock domain.

- **-NO_EQUIvalent_clocks**

An optional switch that prevents the **-Clock_domains** switch from deleting faults in equivalent clock domains.

- **-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains**

An optional switch used with **-Clock_domains** to instruct the tool to exclude the inter-clock faults for synchronous clocks. When you specify this, the tool considers only faults within clock domains when adding or deleting faults by clock domain.

- **-CAPture_procedures** {**ALL** | *capture_procedure_name...*}

A required switch and literal or repeatable string pair that specifies a list of enabled named capture procedures and directs the tool to delete faults that are potentially detectable by any of the specified procedures. The argument choices are as follows:

ALL — A literal that specifies all enabled named capture procedures.

capture_procedure_name — A repeatable string that specifies a particular enabled named capture procedure.

Refer to the [set_capture_procedures](#) command description for information about enabling or turning off named capture procedures.

- **-FRom** *pin...*

An optional switch and repeatable string that sets the start pin or pins of the cone of logic the tool uses to select faults to delete. It directs the tool to perform forward cone tracing from the specified pin or pins until it encounters a stop point. You can specify one or more instance names, rather than pin names. When you specify an instance name with **-from**, the tool uses its output pins when defining the cone.

- **-THrough** *pin...*

An optional switch and repeatable string that sets the through pin or pins of the cone of logic the tool uses to select faults to delete. When you specify this option, the tool performs forward and backward cone tracing from the specified pin or pins until it encounters a stop point in both directions. You can specify one or more instance names, rather than pin names. When you specify an instance name with **-through**, the tool uses its output pins when defining the cone.

- **-TO** *pin...*

An optional switch and repeatable string that sets the end pin or pins of the cone of logic the tool uses to select faults to delete. When you specify this option, the tool performs backward cone tracing from the specified pin or pins until it encounters a stop point. You can specify one or more instance names, rather than pin names. When you specify an instance name with **-to**, the tool uses its input pins when defining the cone.

Note

 When you use **-from**, **-to**, and **-through** with other switches, the selected faults are the intersection of the cones traced for all specified switches.

- **-STOP_at** {**SEQUential_elements** | **SCAN_cells** | **PORTs_only**}

An optional switch and literal pair that sets the stop condition for tracing the cone of logic the tool uses to select faults to delete. By default, the traced logic cone includes only combinational logic, so cone tracing stops at any sequential elements. When you specify “**scan_cells**”, the cone includes non-scan cells and tracing stops only at scan cells. When you specify “**ports_only**”, the cone includes any sequential elements and tracing stops only at primary inputs and outputs.

- -fanout_off_path_stop {on | off}

An optional switch and literal pair that specifies an additional stop condition when tracing the fan-in fault cone backward and reaching a multiple fanout gate G. When this switch is on, tracing stops at gate G unless the cone already includes all of the fanout gates of G. The default is off. You can use a separate command, `set_fault_selection_options`, to change the default of this stop condition.

- -fanin_off_path_stop {on | off}

An optional switch and literal pair that specifies an additional stop condition when tracing the fanout fault cone forward and reaching a multiple fan-in gate G. When this switch is on, tracing stops at gate G unless the cone already includes all of the fan-in gates of G. The default is off. You can use a separate command, `set_fault_selection_options`, to change the default of this stop condition.

- -Stuck_at 01 | 1 | 0

An optional switch and literal pair that specifies the stuck-at or transition faults to delete from the fault list, according to the following table:

	01 (default)	0	1
Stuck-At	stuck-at-0 stuck-at-1	stuck-at-0	stuck-at-1
Transition	slow-to-rise slow-to-fall	slow-to-rise	slow-to-fall

The following switches, which support stuck-at, transition, toggle, Iddq, UDFM, and bridge faults, delete faults at certain locations that are ATPG untestable in functional mode or should not be tested (to avoid over-testing). For bridge faults, the switches apply to any bridge that has at least one end in a specified location. Use the switches to fine-tune the fault population and improve the quality of the tool's coverage statistics. You should take care to ensure that you are familiar enough with the design to understand the effects of these switches on the design.

- -SCAN_Enable

An optional switch that deletes faults that only fan out to the select lines of multiplexers in the scan path. For this switch, a multiplexer is either a MUX simulation primitive or a nonprimitive type multiplexer composed of AND and OR gates. In essence, this switch deletes all faults that are in the fan-in cone of local scan enable signals and are dominated by them.

- -CLOCK_Cones

An optional switch that deletes all faults in the clock cone. The clock cone is the intersection of the fan-in of the sequential element clock ports and the fanout of the clock sources. This switch considers any sequential elements, such as flops, latches, RAMs, and ROMs, not just scan cells.

- **-IO**
An optional switch that deletes faults that either only PIs control or only POs observe. This switch applies only to PIs that are either not defined as a clock, or defined as clock (or read/write control) but constrained to be off during capture.
- **-ASynchronous_controls**
An optional switch that deletes all faults that only fan out to Set/Reset ports of state elements and RAMs.
- **-SCAN_Data**
An optional switch that deletes all bridge faults where at least one of the bridging nets is located on the scan data path.
- **-VERBOSE**
An optional switch that outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the > or >> redirection operators.
By default when you specify wildcard characters for instance (-INSTANCE) or pin (-PIN) names, the tool outputs all found instances or pins matching the wildcard characters. For example:

```
ANALYSIS> delete_faults */irep0/sigdout -verbose
=== Found 1 design pin ===
path_to_instance/irep0/sigdout
```

If you use actual instance or pin names instead of wildcards, then this switch has no effect.
- **> file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- **>> file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.
- **-Udfm_Type name**
An optional switch and string pair that specifies the name of a UDFM type. Use this option to delete all faults associated with a specific UDFM type from the current fault list. The name string is case insensitive and can include any number of asterisk (*) and question mark (?) wildcard characters.
- **-CELL name**
An optional switch and string pair that specifies a library cell. Use this option to delete all faults associated with a specified cell from the current fault list. The name string is case insensitive and can include any number of asterisk (*) and question mark (?) wildcard characters.

- **-MODule *name* (UDFM only)**

An optional switch and string pair that specifies a module. Use this option to delete all faults associated with a specified module from the current fault list. The name string is case insensitive and can include any number of asterisk (*) and question mark (?) wildcard characters.

- **-Class *class_type***

An optional switch and repeatable literal pair that deletes the internal fault entries that belong to the class specified by the *class_type* argument. The *class_type* argument can be either the fault class code or a fault class name. For more information on fault classes, refer to “[Fault Classes](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **-Fault *name***

An optional switch and string pair that specifies a UDFM fault name. The name string is case insensitive and can include any number of asterisk (*) and question mark (?) wildcard characters.

Power-Aware Options (applicable only after you have loaded CPF/UPF power data)

- **-ON_domains**

An optional switch that removes faults on all power-on domains.

- **-OFF_domains**

An optional switch that removes faults on all power-off domains.

- **-Power_domains {*domain_name* ...}**

An optional switch and repeatable string that removes faults on the specified power domains.

- **-Isolation_cells**

An optional switch that removes faults on all isolation cells.

- **-Level_shifters**

An optional switch that removes faults on all level shifters.

- **-REtention_cells**

An optional switch that removes faults on all retention cells.

Examples

Example 1

The following example deletes a stuck-at-0 fault from the current fault list after adding all the faults to the circuit, but before creating patterns:

```
set_system_mode analysis
add_faults -all
delete_faults i_1006/i1 -stuck_at 0
create_patterns
```

Example 2

The following example deletes all stuck-at-0 AU faults. The reduction in AU faults in the statistics report corresponds to the increase in the reported coverages as a result of removing these faults from the calculation. (For information on the formulas used to calculate coverage, refer to “[Testability Calculations](#)” in the *Tessent Scan and ATPG User’s Manual*.)

...	

Example 3

After adding all of the faults in the design, this example removes only the faults from the power domain named PD1:

```
add_faults -all
delete_faults -power_domain PD1
```

Example 4

The following example deletes all UDFM type intra_cell_bridges associated with all library cells that begin with “mux”:

```
delete_faults -udfm_type intra_cell_bridges -cell mux*
```

delete_flat_model

Context: all contexts

Mode: setup

Deletes a flat model that was previously created either by going to system mode analysis or by using the `create_flat_model` command.

Usage

`delete_flat_model`

Description

Deletes a flat model that was previously created either by going to system mode analysis or by using the `create_flat_model` command.

You typically do not need this command because any command you use that invalidates the flat model automatically deletes the flat model at the same time. The tool also automatically deletes the flat model when you enter insertion mode.

In addition, the tool deletes the flat model when you set an attribute on a design module, instance, port, or pin that has the preserve boundary option enabled. For more information, refer to the “`set_attribute_options -preserve_boundary_in_flat_model`” description.

To free up used memory, you can use this command to delete the flat model while still in setup mode if you do not need it anymore.

You cannot use this command to delete a flat model that was read in with the `read_flat_model` command. In this case, you must use the `delete_design` command to delete the flat model.

Arguments

None

Return Values

None

Related Topics

[create_flat_model](#)

[delete_design](#)

[read_flat_model](#)

[set_attribute_options](#)

delete_gate_to_rtl_mapping

Context: all contexts

Mode: setup

Removes the specified rule for post-synthesis/post-layout to RTL instance name-mapping for DEF files.

Usage

```
delete_gate_to_rtl_mapping -instance_name_map_index instance_name_map_index
```

Description

Deletes the specified DEF post-synthesis/post-layout instance to RTL instance name-mapping rule created with the [add_gate_to_rtl_mapping](#) command.

Arguments

- **-instance_name_map_index** *instance_name_map_index*
A required switch and integer value pair that specifies the index of the name-mapping rule to be removed. The index values for existing name-mapping rules are reported with the [report_gate_to_rtl_mapping](#) command.

Examples

The following command removes the name-mapping reported for index 5 shown in the [report_gate_to_rtl_mapping](#) example:

```
delete_gate_to_rtl_mapping -instance_name_map_index 5
```

A subsequent [report_gate_to_rtl_mapping](#) command then reports:

```
report_gate_to_rtl_mapping
Index  Original instance name      Mapped instance name
-----
1      memA                          /MEMORY.mem1
2      memB                          /MEMORY.mem2
3      memC                          /MEMORY.mem3
4      memD                          /MEMORY.mem4
5      memF                          /MEMORY.mem6
```

Related Topics

[add_gate_to_rtl_mapping](#)

delete_icl_modules

Context: all contexts

Mode: setup

Deletes the specified ICL modules from memory.

Usage

```
delete_icl_modules {object_spec | -all} [-silent]
```

Description

If any of the specified ICL modules are instantiated below the current design, the ICL elaboration tree is destroyed and you must recreate it using a new [set_current_design](#) command.

Arguments

- *object_spec*
A value that specifies one or more ICL modules to delete. The value is a Tcl list of one or more ICL module names, or a collection of one or more ICL module objects as returned by the [get_icl_modules](#) command. When this argument is omitted, all ICL modules are deleted.
- **-all**
A switch that specifies to delete all ICL modules in the system.
- **-silent**
An optional argument that specifies to not generate error messages when an ICL module specified by *object_spec* does not exist.

Return Values

None

Examples

The first example deletes three ICL modules. The second example deletes all ICL modules. The third example deletes all ICL modules with a name starting with a, b, or c.

```
delete_icl_modules {mychip tap tdr}  
delete_icl_modules -all  
delete_icl_modules [get_icl_modules {[abc].*}] -regexp]
```

Related Topics

[get_icl_modules](#)

[read_icl](#)

delete_icl_ports

Context: patterns -ijtag, dft

Mode: setup, insertion

Undoes the effect of the `add_icl_ports` command on a specified list of top level ports.

Usage

```
delete_icl_ports { port_objects | -all } [-silent]
```

Description

Undoes the effect of the [add_icl_ports](#) command on a specified list of top level ports.

Arguments

- *port_objects*
A required string that specifies a Tcl list of one or more design port names or a collection of one or more design or icl ports.
The ports in the collection must not have been used as arguments of the `-source` switch of an `add_icl_port` command before. (A port that is already in use as a “source port”, cannot be deleted by means of `delete_icl_ports`.)
- **-all**
A required switch that triggers the deletion of all previous specifications of the [add_icl_ports](#) command.
- **-silent**
An optional switch that specifies to suppress the warning messages that are normally generated when the specified port names do not exist or were never the target of previous [add_icl_ports](#) commands.

Examples

The following example declares then deletes ICL DataInPort D1, and ICL DataOutPorts O1 O2 and O3.

```
set_current_design top
add_icl_ports D1 -type data_in
add_icl_ports {O1 O2 O3} -type data_out
delete_icl_ports {O1 O2 O3}
```

Related Topics

[add_icl_ports](#)

delete_icl_scan_interfaces

Context: patterns -ijtag, dft

Mode: setup, insertion (dft context only)

Deletes the specified scan interfaces previously added by `add_icl_scan_interfaces` from the new ICL top module that is created during ICL extraction.

Usage

```
delete_icl_scan_interfaces name_list | -All
```

Description

Deletes the specified scan interfaces previously added by `add_icl_scan_interfaces` from the new ICL top module that is created during ICL extraction.

You must set the current design with `set_current_design` before using the `delete_icl_scan_interfaces` command.

Arguments

- *name_list*
A list that specifies the names of scan interfaces that ICL extraction deletes from the new top ICL module.
- **-All**
A switch that specifies that all scan interfaces are deleted from the new ICL top module.

Examples

The following example deletes the ScanInterfaces named TAP and Internal from the new ICL top module during ICL extraction:

```
delete_icl_scan_interfaces {TAP Internal}
```

delete_icl_ssn_datapaths

Context: all contexts

Mode: setup, insertion

Deletes the SSN datapath specifications added with the `add_icl_ssn_datapaths` and `set_icl_ssn_datapath_ports` commands.

Usage

```
delete_icl_ssn_datapaths name_list | -all
```

Description

The command `delete_icl_ssn_datapaths` is used to undo specifications that you have made with the `add_icl_ssn_datapaths` and `set_icl_ssn_datapath_ports` commands. You can either remove a single SSN datapath or a list of SSN datapaths, or all SSN datapath specifications. The specified names must have been introduced as SSN datapath identifiers. Deleting a SSN datapath also deletes the associated specifications done by means of the `set_icl_ssn_datapath_ports` command.

Arguments

- *name_list*
A Tcl list of names that are removed from the set of registered SSN datapath identifiers.
- -all
A switch that instructs Tessent Shell to remove all SSN datapath specifications.

Examples

```
SETUP> add_icl_ssn_datapaths mypath
SETUP> delete_icl_ssn_datapaths mypath
SETUP> add_icl_ssn_datapaths mypath
SETUP> set_icl_ssn_datapath_ports -name mypath -clock_inputs bus_clock \
    -bus_data_inputs bus_in[11:0] -bus_data_outputs bus_out[11:0]
SETUP> extract_icl
```

delete_iddq_exceptions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Deletes exceptions to Iddq restrictions added with the `add_iddq_exceptions` command.

Usage

`delete_iddq_exceptions {original_string... | -All}`

Description

Deletes exceptions to Iddq restrictions added with the `add_iddq_exceptions` command.

For more information about IDDQ, see “[IDDQ Test Set Creation](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- *original_string*
A required repeatable string that identifies a site to which you previously applied Iddq exception. The original string is reported by the `report_iddq_exceptions` command and must be one of the following:
 - A string originally input to an `add_iddq_exceptions` command
 - A string generated automatically by the “`analyze_restrictions -Int_float_auto_except`” command.
- **-All**
A required switch that specifies the deletion of all Iddq restrictions.

Examples

The following example removes an Iddq exception:

```
delete_iddq_exceptions /cpu/alu/U2392/
```

Related Topics

[analyze_restrictions](#)

[set_iddq_checks](#)

delete_ijtag_logical_connection

Context: patterns -ijtag

Mode: setup

Removes logical connections previously added to a design. You must specify either the source pin/port or the destination pin/port or both source and destination pins/ports.

Usage

```
delete_ijtag_logical_connection  
    -from source_pin_or_port_name | -to destination_pin_or_port_name
```

Description

You must specify the source pin/port or the destination pin/port or both with this command. If both the source and destination pins/ports are specified, the command removes the logical connection between them. If only the source pin/port is specified, then all logical connections that have that pin/port as the source are removed. If only the destination pin/port is specified, then all logical connections that have that pin/port as the destination are removed.

Arguments

- **-from *source_pin_or_port_name***
A switch and value pair that specifies the source pin/port for the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.
- **-to *destination_pin_or_port_name***
A switch and value pair that specifies the destination pin/port for the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.

Examples

The following example adds three logical connections in the current design, then deletes one logical connection.

```
add_ijtag_logical_connection -from /i2/in -to /i2/out  
add_ijtag_logical_connection -from /i3/in -to /i3/out  
add_ijtag_logical_connection -from /i4/in -to /i4/out  
report_ijtag_logical_connections  
  
// IJTAG Logical Connections:  
// From Source   To Destination   Inversion  
// =====  
// /i2/in       /i2/out         no  
// /i3/in       /i3/out         no  
// /i4/in       /i4/out         no
```

delete_ijtag_logical_connection -from /i4/in -to /i4/out

report_ijtag_logical_connections

```
// IJTAG Logical Connections:  
// From Source To Destination Inversion  
// =====  
// /i2/in /i2/out no  
// /i3/in /i3/out no
```

Related Topics

[report_ijtag_logical_connections](#)

delete_input_constraints

Context: all contexts

Mode: setup, analysis (dft -edt and patterns -scan contexts only)

Removes previously applied constraints from primary input pins.

Usage

Context: dft-scan and dft -test_points

```
delete_input_constraints  
[-ALL] | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs |  
-EQuivalent equivalent_pin...] [constraint_switch]
```

Context: patterns -scan

```
delete_input_constraints  
[-ALL] | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs |  
-EQuivalent equivalent_pin...] [constraint_switch] [-HOLD] [-NO_Z] [-SLOW_pad [-CELL  
model_name]]
```

Context: patterns -ijtag

```
delete_input_constraints  
[-ALL] | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude | -EQuivalent  
equivalent_pin...] [constraint_switch]
```

Description

The delete_input_constraints command removes constraints you previously applied to primary input pins using the [add_input_constraints](#) command.

Arguments

- **-ALL**
An optional switch that specifies to remove all previously applied input constraints, including pin equivalents. This is the default. Constraints for power and ground pins that are added via attributes are not deleted. To remove only pin equivalents, use the -Equivalent switch.
- *primary_input_pin_name*
An optional, repeatable string that specifies the name of a primary input pin from which to remove the constraint.
- **-BIDI_Only**
An optional switch that specifies to remove previously applied constraints only from bidirectional pins.
- **-BIDI_Exclude**
An optional switch that specifies to remove previously applied constraints only from primary input pins that are not bidirectional.

- **-SCAN_Inputs**
An optional switch that specifies to remove previously applied constraints only from scan input pins.
- **-Equivalent *equivalent_pin***
An optional switch and repeatable string that specify the name of a primary input pin from which to remove a previously defined equivalence specification.
- ***constraint_switch***
An optional switch that specifies a particular constraint to remove. The choices, from which you can specify only one, are as follows:
 - C0 — Constant 0
 - C1 — Constant 1
 - CX — Constant X (unknown)
 - CZ — Constant Z (high-impedance)
 - CT0 — Constant TIE0
 - CT1 — Constant TIE1
 - CTZ — Constant TIEZ

Tip

 For additional information about the constraints associated with the preceding switches, refer to the same switches under the [add_input_constraints](#) command.

- C_All — All C-type constraints
- C_Default — All C-type constraints added using any of the following switches with the `add_input_constraints` command: `-All`, `-Bidi_only`, `-Bidi_exclude`, `-Scan_inputs`. This does not include C-type constraints added by specifying the primary input pin name explicitly.
- C_Specified — C-type constraints added by specifying the primary input pin name explicitly.
- **-Hold**
An optional switch that specifies to remove the “hold” restriction, if applicable, from the specified pins. Refer to the description of the `-Hold` argument to the `add_input_constraints` command for more information.
- **-NO_Z**
An optional switch that specifies to remove the “no-Z” restriction, if applicable, from the specified pins. Refer to the description of the `-No_z` argument to the `add_input_constraints` command for more information.

- **-Slow_pad**
An optional switch that specifies to remove the “slow-pad” restriction, if applicable, from the specified pins. Refer to the description of the `-Slow_pad` argument to the `add_input_constraints` command for more information.
- **-CELL *model_name***
An optional switch and string pair that, together with the `-Slow_pad` switch, specifies to prefix the instance name of each instance of the Tessent Cell library model of type *model_name* to the *primary_input_pin_name*, and look up each resulting name as the pin directly driven by the primary input.

Examples

The following example deletes constraints from two primary inputs.

```
delete_input_constraints indata2 -c1  
delete_input_constraints indata4 -c0
```

Related Topics

delete_instances

Context: all contexts

Mode: insertion

Deletes the specified instance objects from the current design.

Usage

`delete_instances obj_spec [-silent]`

Description

The `obj_spec` can be a Tcl list of one or more hierarchical instance names, or a collection of one or more instances.

Arguments

- *obj_spec*
A required value that specifies one or more instances to delete. The value is a Tcl list of one or more hierarchical instance names, or a collection of one or more instances.
- `-silent`
An optional argument that specifies to not generate an error messages when an instance in the `obj_spec` list does not exist.

Examples

Example 1

The following example deletes the two specified instances in the Tcl list:

```
delete_instances {u1/u2 u1/u4}
```

Example 2

The following example deletes the collection of instances returned by the `get_instances` command:

```
delete_instances [get_instances ABC* -hierarchical -of_module XYZ]
```

Related Topics

delete_iprocs

Context: all contexts

Mode: all modes

Deletes the specified list of iProcs attached to the ICL module specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Usage

```
delete_iprocs iprocs_list [-of_module module_name] [-silent]
```

Description

Deletes the specified list of iProcs attached to the ICL module specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

All iProcs attached to the ICL module are deleted when `iprocs_list` is not specified.

Arguments

- ***iprocs_list***
A Tcl list of iProc names.
- `-of_module module_name`
A required switch and value pair that constrains the command to delete only instances of iProcs attached to the module specified by *module_name*.
- `-silent`
An optional switch that specifies to suppress error messages if the specified iProcs or module do not exist.

Return Values

None

Examples

The following example deletes the `test1` iProc from module `mychip` and then searches and deletes any remaining iProcs on `mychip` that begin with “p”.

```
delete_iprocs test1 -of_module mychip  
delete_iprocs [lsearch -inline -all [get_iproc_list p*] -of_module mychip]
```

delete_layout_core_information

Context: patterns -scan_diagnosis

Mode: analysis

In hierarchical layout-aware diagnosis, deletes all core instance data or the core instance data from a specified design.

Usage

```
delete_layout_core_information {-chip_design_name name | -all}
```

Description

To use this command you must have a valid LDB that you previously opened using the `open_layout` command.

Refer to “[Diagnosis for Hierarchical Design](#)” in the *Tessent Diagnosis User's Manual* for more information.

Arguments

- **-chip_design_name *name***
A switch and string pair that specifies to delete the core instance data from the specified design.
- **-all**
A switch that specifies to delete all the core instance data.

Related Topics

[add_layout_core_information](#)

[report_layout_core_information](#)

delete_layout_verification

Context: patterns -scan_diagnosis

Mode: analysis

Reports or deletes stored layout verification information from the current layout database.

Usage

```
delete_layout_verification {-List | -Design design_index_in_list}
```

Description

Reports or deletes stored layout verification information from the current layout database.

Arguments

- **-Design *design_index_in_list***
A required switch and integer pair that specifies the layout verification data the tool deletes. Use the -list switch to print index numbers for all stored design layout verification information.
- **-List**
A required switch that directs the tool to list all the designs and corresponding layout rule violation information stored in the layout database. Each design is listed with its assigned Index number, which is used as an argument to the -design switch. The -list switch does not delete any layout verification information, use the -design switch to delete layout verification data from the database.

Examples

In the following example, the diagnosis lists the layout verification and design information stored in the open_layout database:

```
delete_layout_verification -list  
  
// Note: Layout verification information corresponding to the following  
//       designs can be deleted from the layout database  
//  
// Index      Stored Violation Count   Flat model file name  
// 1.         611                       my_design.flat  
// 2.         643                       other_design_version.flat  
//  
// Note: The current design is my_design.flat (Index 1.)  
// Note: To delete any of the above, please use  
//       delete_layout_verification -design <design index in the list>  
//
```

In the following example, the diagnosis deletes the layout verification information for design index 1 (my_design.flat):

```
delete_layout_verification -design 1
```

```
// Note: Deleting layout verification information corresponding
//       to my_design.flat.
// Warning: Since the layout verification information for the
//          current design has been deleted, the layout will be closed.
```

Related Topics

delete_lfsr_connections

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Removes connections between the specified primary pins and Linear Feedback Shift Registers (LFSRs).

Usage

delete_lfsr_connections *primary_pin*... | **-All**

Description

The delete_lfsr_connections command deletes the connections between the LFSRs and the primary pins specified with the add_lfsr_connections command. You can use the report_lfsr_connections command to display all the current connections between LFSRs and primary pins.

Arguments

- *primary_pin*
A repeatable string that lists the primary pins whose connections to LFSRs you want to delete.
- **-All**
A switch that deletes all of the connections between LFSRs and primary pins.

Examples

The following example changes the definition of an LFSR connection by deleting it and then re-adding it with a new definition:

```
add_lfsrs lfsr1 prpg 5 15 -serial -in
add_lfsr_taps lfsr1 2 3 4
add_lfsr_connections scan_in.1 lfsr1 2
delete_lfsr_connections scan_in.1
add_lfsr_connections scan_in.2 lfsr1 2
```

Related Topics

[add_lfsr_connections](#)

[report_lfsr_connections](#)

delete_lfsr_taps

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Removes the tap positions from a Linear Feedback Shift Register (LFSR).

Usage

```
delete_lfsr_taps lfsr_name {tap_position... | -All}
```

Description

The `delete_lfsr_taps` command deletes the specified LFSR tap positions added with the `add_lfsr_taps` command. To display the current tap positions of all defined LFSRs, use the `report_lfsrs` command.

Arguments

- ***lfsr_name***
A string that specifies the reference name of the LFSR whose tap positions you want to delete.
- ***tap_position***
A repeatable string that specifies the list of tap positions that you want to delete from the *lfsr_name*.
- **-All**
A switch that deletes all of the tap positions from the *lfsr_name*.

Examples

The following example changes an LFSR tap position by deleting it and then adding a new tap position:

```
add_lfsrs lfsr1 prpg 5 15 -serial -in
add_lfsrs lfsr2 Prpg 5 13 -serial -in
add_lfsr_taps lfsr1 2 3 4
add_lfsr_taps lfsr2 1 3
delete_lfsr_taps lfsr1 3
add_lfsr_taps lfsr1 1
```

Related Topics

[add_lfsr_taps](#)

[report_lfsrs](#)

[set_lfsrs](#)

delete_ifsrs

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Removes the specified Linear Feedback Shift Registers (LFSRs).

Usage

delete_ifsrs *lfsr_name*... | **-All**

Description

The delete_ifsrs command deletes LFSRs defined with the add_ifsrs command. You can use the report_ifsrs command to display a list of the current LFSRs with their current values and tap positions. When you delete an LFSR, the tool also deletes all its taps and pin connections.

Arguments

- *lfsr_name*
A repeatable string that specifies the reference names of the LFSRs that you want to remove.
- **-All**
A switch that deletes all defined LFSRs.

Examples

The following example changes the definition of an LFSR by deleting it and then re-adding it with a new definition:

```
add_ifsrs lfsr1 prpg 5 15 -serial -in
add_ifsrs lfsr2 prpg 5 13 -serial -in
add_ifsrs lfsr3 prpg 5 11 -parallel -out
delete_ifsrs lfsr3
add_ifsrs lfsr3 prpg 5 11 -parallel -in
```

[set_ifsrs](#)

delete_lists

Context: `dft -edt, patterns -scan`

Mode: analysis

Removes pins from the pin list the tool monitors and reports on during simulation.

Usage

`delete_lists` *pin_pathname*... | **-All**

Description

The `delete_lists` command removes from the monitored pin list, pins that you previously added to the list using the [add_lists](#) command. To review the current list of pins, use the [report_lists](#) command. To put additional pins on the list, use the `add_lists` command.

Arguments

- *pin_pathname*
A repeatable string that specifies the pins you want to remove from the monitored pin list.
- **-All**
A switch that removes all currently listed pins from the monitored pin list.

Examples

The following example removes an extra added output pin from the monitored pin list:

```
add_lists /i_1006/o /i_1007/o /i_1008/o  
report_lists
```

```
3 pins are currently monitored.  
/i_1006/o  
/i_1007/o  
/i_1008/o
```

```
delete_lists /i_1007/o  
report_lists
```

```
2 pins are currently monitored.  
/i_1006/o  
/i_1008/o
```

[set_list_file](#)

delete_loadboard_loopback_pairs

Context: patterns -ijtag, -scan, -scan_diagnosis, -scan_retargeting

Modes: setup

Prerequisites: Design must be elaborated prior to using this command.

Deletes any loopback connection associated with the specified ports.

Usage

```
delete_loadboard_loopback_pairs -all | port_object_spec
```

Description

You use this command to delete the loopbacks associated with specified ports or all of the loopbacks that were created with the [add_loadboard_loopback_pairs](#) command.

Arguments

- **-all**
A switch that specifies to delete all loopbacks.
- *port_object_spec*
A required string that lists the ports from which to delete associated loopbacks. You may specify one or both ports of the associated loopback pairs.

Examples

Example 1

This example shows one loopback pair being deleted using the *port_object_spec*:

```
add_loadboard_loopback_pairs -inputs {din[4] ue} -outputs {dout[5] dout[0]}  
report_loadboard_loopback_pairs
```

```
-----  
Inputs  Outputs  AC Time to Z  
-----  
din[4]  dout [5]  N/A  
ue      dout [0]  N/A  
-----
```

```
delete_loadboard_loopback_pairs {dout[5] din[4]}  
report_loadboard_loopback_pairs
```

```
-----  
Inputs  Outputs  AC Time to Z  
-----  
ue      dout [0]  N/A  
-----
```

Example 2

This example shows how you delete all loopback pairs using the **-all** switch:

```
add_loadboard_loopback_pairs -inputs {din[4] ue} -outputs {dout[5] dout[0]}  
report_loadboard_loopback_pairs
```

```
-----  
Inputs  Outputs  AC Time to Z  
-----  
din[4]  dout[5]  N/A  
ue      dout[0]  N/A  
-----
```

```
delete_loadboard_loopback_pairs -all  
report_loadboard_loopback_pairs
```

```
-----  
Inputs  Outputs  AC Time to Z  
-----  
-----  
-----
```

delete_misrs

Context: pattern -scan

Mode: setup, analysis

Deletes MISRs you specify with the `add_misrs` command.

Usage

```
delete_misrs {-all | misr_name}
```

Description

Deletes MISRs you specify with the `add_misrs` command.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

Arguments

- **-all**
A required switch that specifies removing all MISRs.
- ***misr_name***
A required repeatable string that specifies the name of the MISR.

Examples

This example deletes a previously added MISR called `misr_0`, and then re-adds the MISR as `blk1_misr`.

```
add_misrs misr_0 -size 24 -seed 000000 -taps 21 22 24
delete_misrs misr_0
add_misrs blk1_misr -size 24 -seed 0000 -taps 21 22 24
report_misrs -all
list of MISRs
blk1_misr MISR length=24 in_stream_taps=20,21,23
blk1_misr_pre_unload_value = 00000000000000000000000000000000
```

Related Topics

[add_misrs](#)

delete_multicycle_paths

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Removes definitions of multicycle paths previously read in using the read_sdc command.

Usage

```
delete_multicycle_paths [-All] [-Verbose]
  [-Cycles integer [-Start | -End ]]
  [-From source_node... | -FROM_Clock clock_signal_name...]
  [-TO sink_node... | -TO_Clock clock_signal_name...]
  [{-Through through_node...} ...]
```

Description

The delete_multicycle_paths command deletes from the tool's internal database, multicycle path definitions previously read in by the read_sdc command.

Arguments

Tip

 When using the following arguments, you can include asterisks (*) in pin or instance pathnames. The command treats an asterisk as a wildcard character, enabling you to use it to match many pathnames in the design.

- -All
An optional switch that specifies to delete all multicycle path definitions.
- -Verbose
An optional switch that directs the tool to display the definition of each deleted multicycle path as it is deleted.
- -Cycles *integer* [-Start | -End]
An optional switch and integer value that define the multicycle paths to delete when the path's cycle count is equal to the value specified by *integer*.
[-Start | -End]
These argument options for the -Cycles switch, specify the cycle count is associated with the clock of the start point (-from) or the end point (-to). The default, -End, is uses the end point clock (-to).
- -From *source_node...*
An optional switch and repeatable string pair that specifies the starting point of a multicycle path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the output pins of the instance to be starting points. For a clock PI, the tool considers the outputs

of all the non-transparent latches, flip-flops and RAMs associated with the clock PI to be starting points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

If a specified source node does not translate to an internal gate, the tool transcripts an error message and does not delete the multicycle path definition.

- **-FROM_Clock** *clock_signal_name...*

An optional switch and repeatable string pair that specifies the starting point of a multicycle path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of a clock signal and considers the outputs of all non-transparent latches, flip-flops and RAMs associated with this clock signal to be starting points.

If a specified clock signal name does not translate to an internal gate, the tool transcripts an error message and does not delete the multicycle path definition.

- **-TO** *sink_node...*

An optional switch and repeatable string pair that specifies the end point of a multicycle path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the input pins of the instance to be end points. For a clock PI, the tool considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with the clock PI to be end points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

If a specified sink node does not translate to an internal gate, the tool transcripts an error message and does not delete the multicycle path definition.

Note

 For two port latches with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “delete_multicycle_paths... -to CLK2” would delete_multicycle_paths that have an end point at D2.

- **-TO_Clock** *clock_signal_name...*

An optional switch and repeatable string pair that specifies the end point of a multicycle path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of an internal clock signal and considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with this clock to be end points.

If a specified clock signal name does not translate to an internal gate, the tool transcripts an error message and does not delete the multicycle path definition.

- -Through *through_node...*

An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the multicycle path must pass. A valid through node is a pin or instance pathname. Clock PIs are not supported as through nodes and the tool makes no attempt to determine if a pin pathname is that of an internal clock pin.

When you use multiple -Through arguments, the tool considers their order left-to-right in the command string to be the order in which a signal would pass through the nodes on the specified multicycle path. For example, the following multicycle path specification:

```
delete multicycle paths -from G -through H I -through J
K -to L
```

specifies all paths that start from G, pass through either H or I, then pass through J or K, and end at L. If you do not use the -Through argument when specifying a path, the tool considers all paths from the specified starting points to the specified end points to be false paths.

If a specified through node does not translate to an internal gate, the tool transcripts an error message and does not delete the multicycle path definition.

Examples

The following example displays current multicycle path definitions, then deletes one of them, echoing its definition as it is deleted:

```
report multicycle_paths -all
```

```
// Multicycle Path -from /my_design/a -through /my_design/u1 -cycles 2
// Multicycle Path -to /my_design/c -cycles 3
// Multicycle Path -through /my_design/u24 /my_design/u25 -cycles 2
// Total reported multicycle paths = 3
```

```
delete multicycle_paths -verbose -to /my_design/c
```

```
// Multicycle Path -to /my_design/c (/my_design/c/Y (130)) -cycles 2
// Deleted 1 multicycle path.
```

Refer to the [add_false_paths](#) command for examples of signal matches for pathnames specified using the asterisk (*) wildcard character.

delete_nets

Context: all contexts

Mode: insertion

Removes net objects inside an instance of a design module.

Usage

`delete_nets` *obj_spec* [-silent]

Description

You cannot delete a net that has a fanin or fanout. You can delete only dangling nets.

You cannot delete a net that is also a pin of an instance. You can delete the corresponding input pin using the `delete_pins` command, but the net remains if it has objects in its fanout. You can delete the corresponding output pin using the `delete_pins` command, but the net remains if it has objects in its fanin.

In general, you cannot delete a net that is driven by any RTL construct; however, an exception is that you can delete a dangling net driven by a Verilog assign statement. When you delete such a net, you also delete the assign statement.

Arguments

- *obj_spec*
A required value that specifies a Tcl list of one or more net names or a collection of one or more net objects as returned by the `get_nets` command. If the specified net object is part of a bus net, the entire bus is deleted.
- -silent
An optional argument that specifies to ignore specified objects that do not exist and to not generate error messages.

Examples

Example 1

The following example creates a connection between two pins using a specific net name. Once created, the net cannot be deleted until it is no longer used in any connection.

```
create_connections INSTA/I1 INSTB/O1 -net_name mynet  
  
get_nets mynet  
{mynet}  
  
delete_net mynet
```

```
// Error: Cannot remove net 'mynet' in scope 'mychip' as it is being used
// in expression(s).
// Error: Error on 'delete_nets' at 'mynet'.
```

```
delete_connections { INSTA/I1 INSTB/O1}
```

```
delete_net mynet
```

```
get_nets mynet -silent
```

```
{}
```

Example 2

The following example checks for nets inside instance u1 with no fanin, disconnects their fanout and deletes them.

```
foreach_in_collection net [get_nets u1/*] {  
  if {[sizeof_collection [get_fanins $net]] == 0} {  
    delect_connections [get_fanouts $net -stop_on pin]  
    delete_nets $net  
  }  
}
```

delete_nofaults

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Removes the nofault settings from either the specified pin or instance/module pathnames.

Usage

```
delete_nofaults {-All | modulename ... -Module [-PIN module_pin_pathname ...] |  
  object_expression ... [-PIN | -Instance]} [-Stuck_at {01 | 0 | 1}]  
  [-Class {System | User | Full}] [-VERBose] [(> | >>) file_pathname]
```

Description

The delete_nofaults command deletes nofault settings you added using the add_nofaults command.

You can optionally specify nofault settings that have a specific stuck-at or transition value. For the latter, you specify 0 for “slow-to-rise” and 1 for “slow-to-fall” transition faults. If you do not specify a stuck-at (transition) value when deleting a nofault setting, the command deletes both stuck-at (transition) nofault settings.

You can use the report_nofaults command to display all the current nofault settings.

You can also optionally specify nofault settings that have a specific class code: user-defined, system netlist, or both. If you do not specify a class code, then the command deletes the nofault setting from the user class.

Arguments

- **-All**
A switch that deletes all nofault settings.
- ***modulename***
A repeatable string that specifies the name(s) of the module(s) from which you want to delete nofault settings. You must include the -Module switch when you specify a module name.
- **-Module**
A switch that specifies interpretation of the *modulename* argument as a module pathname. All instances of these modules are affected. You can use the asterisk (*) and question mark (?) wildcards for the *modulename* argument, and the tool deletes the nofault for all matching modules or library models.

When you follow the -Module switch with the optional -PIN switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given module name and deletes nofaults for every pin specified in module_pin_pathname list.

- ***object_expression***

A string representing a list of pathnames of instances or pins from which you want to delete nofault settings. You can use regular expressions, which may include any number of asterisk (*) and question mark (?) wildcard characters.

Pin pathnames must be Tessent Cell library cell instance pins, also referred to as design level pins. If the object expression specifies a pin within an instance of a Tessent Cell library model, the tool ignores it. By default, pin pathnames are matched first. If a pin pathname match is not found, the tool next tries to match instance pathnames. You can force the tool to match only pin pathnames or only instance pathnames by including the `-Pin` or `-Instance` switch after the *object_expression*.

- `-Pin`

An optional switch that specifies to use the preceding object expression to match only pin pathnames; the tool then deletes nofault settings from all the pins matched.

- `-Instance`

An optional switch that specifies to use the preceding object expression to match only instance pathnames; the tool then deletes nofault settings from all boundary and internal pins of the instances matched.

- `-Stuck_at 01 | 0 | 1`

An optional switch and literal pair that specifies the stuck-at or transition values from which you want to remove a nofault setting. The choices are as follows:

01 — A literal specifying that for stuck-at faults the tool delete both “stuck-at-0” and “stuck-at-1” nofault settings; or for transition faults the tool delete both “slow-to-rise” and “slow-to-fall” nofault settings. This is the default.

0 — A literal that deletes only the “stuck-at-0” nofault settings (“slow-to-rise” nofault settings for transition faults).

1 — A literal that deletes only the “stuck-at-1” nofault settings (“slow-to-fall” nofault settings for transition faults).

- `-Class User | System | Full`

An optional switch and literal pair that specifies the source (or class) of the nofault settings that you want to delete. The valid literals are as follows:

User — A literal that deletes the user-entered nofault settings. This is the default.

System — A literal that deletes netlist-based nofault settings.

Full — A literal that deletes all the nofault settings in the user and system classes.

- `-VERbose`

By default when you specify wildcard characters for instance (`-INstance`) or pin (`-PIN`) names, the tool outputs a summary message similar to the following:

```
// Note: Adding faults for 330 fault sites.
```

delete_nofaults

When you specify the optional `-VERBOSE` switch, then the tool outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the `>` or `>>` redirection operators.

If you use actual instance or pin names instead of wildcards, then this switch has no effect.

- `> file_pathname`

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- `>> file_pathname`

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example deletes nofault settings from the pins of instance `i_1007` and then adds all faults to the circuit, thereby enabling the tool to add faults to the pins of the `i_1007` instance:

```
add_nofaults i_1006 i_1007 i_1008 -instance
delete_nofaults i_1007 -instance
set_system_mode analysis
add_faults -all
```

delete_nonscan_instances

Context: dft, dft -scan, dft -test_points

Mode: setup

Resets any user-specified `is_non_scannable` attribute on the specified objects.

Usage

```
delete_nonscan_instances -INStances instance_spec | -Modules module_spec | -scan_elements  
  scan_element_spec | -All | -unmapped_flop_cells | -library_models
```

Description

Resets any user-specified `is_non_scannable` attribute on the specified objects, thus stopping to exclude them from the scan insertion process.

The `delete_nonscan_instances` command resets the user-specified `is_non_scannable` attribute (see [add_nonscan_instances](#)) on the specified instances, all instances within the specified modules, the specified scan elements, or all instances. Please note that if the `is_non_scannable` attribute was set for any other reason(s), it remains set after this operation.

Arguments

- `-INStances instance_spec`
An optional switch and value pair that specifies to delete the specified instances from the non-scan instance list. *instance_spec* can be a Tcl list of one or more instances or a collection of one or more instances. If the instance is hierarchical, then all instances beneath it are also deleted from the non-scan instance list.
- `-Modules module_spec`
An optional switch and value pair that specifies to delete all instances within the specified modules from the non-scan instance list. *module_spec* can be a Tcl list of one or more modules or a collection of one or more modules. Note: `module` may specify the name of a Verilog module, or a Tessent library model.
- `-scan_elements scan_element_spec`
An optional switch and value pair that specifies to delete the specified scan elements from the non-scan scan_element list. *scan_element_spec* can be a Tcl list of one or more scan elements or a collection of one or more scan elements.
- `-All`
An optional switch that specifies to delete all instances from the non-scan instance list.
- `-unmapped_flop_cells`
An optional switch that specifies to delete from the non-scan instance list every flop cell not already mapped to a scan cell in the design.

- `-library_models`

An optional switch that specifies to delete from the non-scan instance list all `nonscan_instances` that were marked as such by using the `-module` switch followed by a Tessent library model name. This switch serves as a replacement for the obsolete `"delete_(non)scan_models -all"` command.

Examples

The following example deletes an extra sequential non-scan instance called `i_1007`.

```
add_nonscan_instances -instances i_1006 i_1007 i_1008  
delete_nonscan_instances -instances i_1007  
insert_test_logic
```

Related Topics

[add_nonscan_instances](#)

[report_seq_transparent_procedures](#)

delete_notest_points

Context: dft -scan, dft -test_points

Mode: setup, analysis

Enables test logic insertion in the specified regions.

Usage

```
delete_notest_points {pin_pathname... | instance_pathname... | instance_expression} |  
-ALL | {-Path critical_pathname} | -ALL_Paths}
```

Description

The `delete_notest_points` command is used to enable test logic insertion in regions of the design that were previously excluded from use because the `add_notest_points` command was used, or the underlying `no_control_point`/`no_observe_point` attributes were set directly. This command works by setting the `no_control_point` and `no_observe_point` attributes to false (which enables test logic insertion). This means a simple scenario such as preventing test points everywhere in the design except for one particular block can be done as follows:

```
add_notest_points /
```

```
delete_notest_points /block1
```

One obvious problem is that the `no_control_point` and `no_observe_point` attributes actually have three values (true, false, and unspecified). Simply setting the attribute for the top level instance to false when “`delete_notest_points -all`” is issued does not produce the required result. Instead, the `-all` switch actually sets the `no_control_points` and `no_observe_points` attributes to unspecified for all instances and `pin_pathnames` within the design. This also occurs when you use “`delete_notest_points /`”.

For more information, refer to [Attribute Inheritance Behavior](#) in Chapter 6.

Arguments

- ***pin_pathname***
A repeatable string that specifies a list of pins on which you want to enable test logic insertion.
- **-All**
A switch that enables test logic insertion in the entire netlist by setting the `no_control_point` and `no_observe_point` attributes to unspecified for all `pin_pathnames`, `instance_pathnames`, and `instance_expressions`.
- ***instance_pathname***
A required repeatable string that enables test logic insertion on or inside the specified instance by setting the `no_control_point` and `no_observe_point` attributes to false for this instance.

Note

 The no_control_point and no_observe_point attribute for the gate-pins inside this instance are NOT affected in any way.

- ***instance_expression***

A string representing a list of instances within the design. The string *instance_expression* is defined as:

```
{ string | string * } ...
```

The asterisk (*) is a wildcard that enables you to match many instances in a design. Any expression that does not contain an asterisk (*) matches exactly zero or one instance.

This argument does not support pathnames to objects below the instance level of a Tessent Cell library model. You can use a pathname expression to select several instances and the tool then enables test logic insertion for all the pins on those instances; but if the expression specifies a location below the instance level of a Tessent Cell library model, the tool reports an error message.

- **-Path *critical_pathname* (dft -test_points context only)**

A required switch and name pair that specifies to delete the named critical path. You can list the names of the critical paths using the [report_notest_points](#) command with the -Paths switch. For more information on the format of the file, refer to “[The Path Definition File](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **-ALL_Paths**

A required switch that specifies to delete all critical paths.

Examples

Example 1

The following example deletes an incorrect notest circuit point and corrects it with a new circuit point before performing testability analysis:

```
set_system_mode analysis
add_notest_points tr_i ts_i
delete_notest_points tr_i
add_notest_points tr_io
```

Example 2

You must be careful when using the add and delete_notest_point commands in conjunction with introspection, as shown in the following example:

```
add_notest_points [get_instances -below_instance /block1]
delete_notest_points /block1/block2]
```

In this example, the get_instances command returns block3, which is the only instance inside block1 and block2.

Figure 3-33. Hierarchical Test Logic Insertion Example

The attributes are explicitly set for each of these low-level objects. However, the `delete_notest_points` command simply sets the attribute for the instance `block2` to false. Because the attributes for `block1/block2` are deleted, the tool inserts test logic in the gates/pins/nets inside `block2`. However, any other module that is instantiated below `block2` (`block3` in this example) remain out of bounds when inserting test logic. This is because the attribute was set specifically for all the instances below `/block1`. If you want to insert test logic for `block3`, then you should instead use the following command:

```
delete_notest_points [get_instances -below /block1/block2]
```

delete_output_masks

Context: dft, dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Removes the masking of the specified primary output pins.

Usage

delete_output_masks *primary_output...* | **-All**

Description

The tools use primary output pins as the observe points during the fault detection process. When you mask a primary output pin with the `add_output_masks` command, the tools mark that pin as an invalid primary output during the fault detection process.

You can set a default mask for all output and bidirectional pins using the [set_output_masks](#) command. You can add a hold value to a default mask with the `add_output_masks` command, or remove a hold value using the `delete_output_masks` command. To turn off the default masks for all output pins, you must use the “`set_output_masks Off`” command.

Note

The `delete_output_masks` command can only be used to delete pin constraints added in the same mode. Pin constraints added in setup mode cannot be deleted in analysis mode.

Arguments

- *primary_output*
A repeatable string that specifies the names of the primary output pins that you want to unmask.
- **-All**
A switch that un.masks all primary outputs masked using the `add_output_masks` command.

Examples

The following example first incorrectly chooses two of the design’s primary output pins to mask. The example then un.masks the one primary output that was inappropriate, masks the correct primary output, and then displays the complete list of currently-masked primary output pins no longer available as observation points:

```
add_output_masks q1 qb3
delete_output_masks q1
add_output_masks qb1
report_output_masks
```

```
TIEX      qb1
TIEX      qb3
```

delete_pattern_trigger

Context: patterns -silicon_insight

Mode: all modes

Deletes pattern triggers set with the add_pattern_trigger command.

Usage

delete_pattern_trigger *pattern_name* [-vector_address *vector_address*]

Arguments

- *pattern_name*
A required string that specifies the name of the pattern from which to delete the trigger.
- -vector_address *vector_address*
An optional switch and nonnegative integer that specifies the vector address for the trigger to delete. If you do not specify an address, the command deletes all pattern triggers.

delete_patterns

Context: dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis, patterns -ijtag

Mode: analysis

Deletes the current pattern set.

Usage

Context: patterns -scan

```
delete_patterns [-external | -internal] [-pattern_sets [chain] [scan]] [-keep_fault_status] [-force]
```

Context: patterns -ijtag

```
delete_patterns [-pattern_sets pattern_set_list] [-force]
```

Context: patterns -scan_retargeting

```
delete_patterns -core name [-mode name] [-silent]
```

Description

This command removes either the internal or external pattern set or both from the current session.

You can only delete generated pattern sets (that is, patterns generated by the tool and not read in) that have been written out using the [write_patterns](#) command, unless you use the `-force` switch. This restriction prevents you from deleting patterns that you have generated but have not yet written out to disk. In the `-ijtag` context, you can delete only patterns that have been closed.

Arguments

- `-external | -internal` (**patterns -scan context only**)
Optional switches that specify which pattern source to remove. By default, the command removes both internal and external pattern sets.
- `-pattern_sets [chain] [scan]` (**patterns -scan only**)
An optional switch and keyword pair that specifies which pattern type (scan or chain) to remove from the current session. By default, the tool removes both scan and chain patterns.
- `-pattern_sets pattern_set_list` (**-ijtag and patterns -scan_retargeting context only**)
An optional switch and string that specifies a Tcl list of pattern set names that were created using the [open_pattern_set](#) command. When you do not use this switch, the command deletes all pattern sets.
- `-keep_fault_status` (**-scan context only**)
Optional switch that keeps the current fault status when removing the internal patterns. When deleting the internal patterns, the status of existing faults is reset by default if you do not use this switch.

delete_patterns

- **-force**
An optional switch that forces removing the internal patterns even when they are not stored previously. By default, the tool does not permit you to remove the unsaved internal patterns. However, the **-force** option enables you to delete the unsaved internal patterns without this safeguard. You can always remove the external patterns.
- **-core *name* (patterns -scan_retargeting only)**
A required switch that specifies the cores from which pattern sets are to be deleted. If the core ***name*** does not exist, the patterns for all cores are deleted in the pattern retargetable phase.
- **-mode *name* (patterns -scan_retargeting only)**
An optional switch that specifies which modes of the core the patterns should be deleted from. If **-mode** is not specified, all modes of the core are deleted.
- **-silent (patterns -scan_retargeting only)**
An optional switch that specifies not to report patterns as they are deleted. By default, deleted patterns are reported.

Examples

Example 1

The following example removes all pattern sets currently in memory:

```
delete_patterns
```

Example 2 (-scan context)

The following example removes only the chain patterns from the internal pattern set. The **-force** option suppresses the error that would otherwise occur if you had not already saved the internal patterns using the `write_patterns` command.

```
delete_patterns -internal -pattern_sets chain -force
```

Example 3 (-ijtag context)

The following example removes only the patterns in the Tcl list named `pattern_list5`:

```
delete_patterns -pattern_sets patterns_list5
```

Related Topics

[write_patterns](#)

[open_pattern_set](#)

delete_pins

Context: all contexts

Mode: insertion

Removes pin objects from a design module instance.

Usage

```
delete_pins obj_spec [-silent]
```

Description

If the pin to be deleted has an internal connection, the internal nets associated to the pin are kept; otherwise they are removed too.

Note

You should be aware that deleting one bit of a bus deletes the entire bus.

Arguments

- *obj_spec*

A required value that specifies a Tcl list of one or more pin names, or a collection of one or more pin objects as returned by the `get_pins` command. If the specified pin object is part of a bus net, the entire bus is deleted.

- `-silent`

An optional argument that specifies to not generate an error message if an object within the specified `obj_spec` does not exist.

Examples

Example 1

The following example deletes the specified pins names. On instance `u1`, pin A is a scalar port, pin B is a bus pin with indices `[3:0]`, and port C is also a bus port with indices `[7:0]`. All three pins are completely deleted even though the complete bus range was not specified for pins B and C.

```
get_pins {u1/A u1/B u1/C}
```

```
{u1/A u1/B[3] u1/B[2] u1/B[1] u1/B[0] u1/C[7] u1/C[6] u1/C[5] u1/C[4] u1/C[3] u1/C[2] u1/C[1] u1/C[0]}
```

```
delete_pins {u1/A u1/B u1/C[1]}  
get_pins {u1/A u1/B u1/C}
```

```
// Warning: No result. Please check your filtering options.  
{}
```

Example 2

The following example deletes the collection of pin objects returned by the `get_pins` command.

```
delete_pins [get_pins {u1/A u1/B u1/C[1]} -silent]
```

Related Topics

[create_pin](#)

[get_icl_pins](#)

[get_icl_ports](#)

[get_nets](#)

delete_ports

Context: all contexts

Mode: insertion

Removes port objects from a design module.

Usage

```
delete_ports obj_spec1 [-on_module obj_spec2] [-silent]
```

Description

If the port to be deleted has an internal connection, the internal nets associated to the port are kept; otherwise they are removed too.

If *obj_spec1* is a collection of ports, those names refers to ports on specific modules and the specified *-on_module* option is ignored.

Note

Deleting one bit of a bus port deletes the entire bus port.

Arguments

- *obj_spec1*
A required value that specifies a Tcl list of one or more port names or a collection of one or more port objects.
- *-on_module obj_spec2*
An optional switch and value pair that specifies the module from which the ports are to be deleted. The *obj_spec2* value can be the name of a module or a module object returned by the command. If the *-on_module* switch is not specified, this command deletes the port from the current design, which is the module specified by the *set_current_design* command. You cannot delete a port on a module that was read in from a file and that is not instantiated inside the current design. It is possible to delete ports on modules created with the *create_module* command.
- *-silent*
An optional argument that specifies to not generate an error message if an object within the specified *obj_spec1* or *obj_spec2* does not exist.

Examples

Example 1

The following example deletes the specified port names of module ModA. On ModA, port A is a scalar port, port B is a bus port with indices [3:0], and port C is also a bus port with indices [7:0]. All three ports are completely deleted even if the complete bus range was not specified for port B and C.

delete_ports

delete_ports {A B C[1]} -on_module ModA

Example 2

The following example deletes the collection of port objects returned by the `get_ports` command. Notice that the `-on_module` option is not specified for the `delete_ports` command because the port objects returned by the `get_ports` command are already associated to a specific module.

delete_ports [get_ports {A B C[1]} -of_module ModA]

[create_port](#)

[get_icl_ports](#)

delete_primary_inputs

Context: all contexts

Mode: setup

Removes the specified primary inputs from the existing flat model or, if a flat model does not yet exist, from the flattened result.

Usage

```
delete_primary_inputs {net_pathname... | primary_input_pin... | -All}  
  [-Class {User | System | Full}]
```

Description

The `delete_primary_inputs` command deletes from a circuit the primary inputs that you specify. You can delete either the user class, system class, or full classes of primary inputs. If you do not specify a class, the tool deletes the primary inputs from the user class.

You can display a list of any class of primary inputs by using the [report_primary_inputs](#) command.

Note

 Once you delete a primary input pin with this command, adding the pin back again with the `add_primary_inputs` command does not create the same pin. Bus information is lost and the pin is marked as user-added. Take care to use `delete_primary_inputs` only if you want to truly delete a pin from the design so it is not used.

Arguments

- ***net_pathname***
A repeatable string that specifies the circuit connections that you want to delete. You can specify the class of primary inputs to delete with the `-Class` switch.
- ***primary_input_pin...***
A repeatable string that specifies a list of primary input pins that you want to delete. You can specify the class of primary inputs to delete with the `-Class` switch.
- **-All**
A switch that deletes all primary inputs. You can specify the class of primary inputs to delete with the `-Class` switch.
- **-Class User | System | Full**
An optional switch and literal pair that specifies the class code of the designated primary input pins. The valid class code literal names are as follows:
User — A literal specifying that you added the primary inputs using the `add_primary_inputs` command. This is the default class.

delete_primary_inputs

System — A literal specifying that the primary inputs derive from the netlist.

Full — A literal specifying that the primary inputs consist of both user and system classes.

Note

In `dft -scan` context and `dft -test_points` context, the `delete_primary_input -class system` or `-class full` are not permitted.

Examples

The following example deletes an extra added primary input from the user class of primary inputs:

```
add_primary_inputs indata2 indata4 indata6  
delete_primary_inputs indata4 -class user
```

Related Topics

[add_primary_inputs](#)

[report_primary_outputs](#)

delete_primary_outputs

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Removes the specified primary outputs from the existing flat model or, if a flat model does not yet exist, from the flattened result.

Usage

```
delete_primary_outputs {net_pathname... | primary_output_pin... | -All}  
[-Class {User | System | Full}]
```

Description

The delete_primary_outputs command deletes from a circuit the primary outputs that you specify. You can delete either the user class, system class, or full classes of primary outputs. If you do not specify a class, the tool deletes the primary outputs from the user class.

You can display a list of any class of primary outputs by using the report_primary_outputs command.

Note

 Once you delete a primary output pin with this command, adding the pin back again with the add_primary_outputs command does not create the same pin. Bus information is lost and the pin is marked as user-added. Take care to use delete_primary_outputs only if you want to truly delete a pin from the design so it is not used.

Arguments

- *net_pathname*
A repeatable string that specifies the circuit connections that you want to delete. You can specify the class of primary outputs to delete with the -Class switch.
- *primary_output_pin*
A repeatable string that specifies a list of primary output pins that you want to delete. You can specify the class of primary outputs to delete with the -Class switch.
- -All
A switch that deletes all primary outputs. You can specify the class of primary outputs to delete with the -Class switch.
- -Class User | System | Full
An optional switch and literal pair that specifies the class code of the primary output pins that you specify. The valid literal names are as follows:
User — A literal specifying that the list of primary outputs were added using the add_primary_outputs command. This is the default class.

System — A literal specifying that the list of primary outputs derive from the netlist.

Full — A literal specifying that the list of primary outputs consists of both the user and system class.

Examples

The following example deletes a primary output from the system class of primary outputs:

```
delete_primary_outputs outdata1 -class system
```

Related Topics

[add_primary_outputs](#)

[report_primary_outputs](#)

delete_processors

Context: unspecified, `dft -edt`, `patterns -scan`

Mode: setup, analysis, insertion (`dft -edt` context only)

Removes processor definitions previously specified with the `add_processors` command.

Usage

`delete_processors [hostname[:cpus]]...`

Description

Removes processor definitions previously specified with the `add_processors` command.

The `delete_processors` command deletes secondary processor definitions you previously specified using the `add_processors` command. When you issue the command with no arguments, the tool deletes any additional local (primary) threads and discontinues all current secondary processes. If you specify one or more *hostname* arguments, the tool discontinues secondary processes only on the specified host machines. If you include *:cpus* with *hostname*, the tool discontinues only the specified number of secondary processes on that host machine. Without the *:cpus*, all current secondary processes on that host machine are discontinued. When specifying *hostname*, you must specify the network name of the machine, even if it was originally selected by an LSF, SGE, or custom job scheduler.

Be aware that the process run by an LSF, SGE, or custom job scheduler is a script rather than the actual secondary process. If you discontinue these secondary processes with the `delete_processors` command, the corresponding scripts also terminate.

Tip

 Alternatively, you can end execution of the scripts by using the job scheduler commands (SGE's `qdel`, LSF's `bkill`, or whatever is used by the job scheduler invoked by the `add_processors` Generic command) or a Linux kill command. There is a small delay before the secondary process is actually shut down to permit for the detection of the script death and for the shutdown to be coordinated with the primary process. Secondary processes shut down in this manner appear to have died in the primary process's transcript. This is normal behavior. Detection of script deaths occurs only during the `add_processors`, `delete_processors`, and `report_processors` commands; you can also see these deaths when actively using the processes. You can force detection from the command line without other side effects by issuing the `report_processors` command with no arguments.

Arguments

- *hostname*

A repeatable string that specifies a host machine you previously defined with the [add_processors](#) command or received via a job scheduler. The hostname choices are as follows:

machine_name — A string that specifies the host machine by its network name.

LOCALHOST — A literal that specifies the host machine is the machine on which you invoked the tool.

IPaddress — A string that specifies the host machine by its IP address.

- *:cpus*

An optional colon (:) and positive integer pair that specifies the number of processes to delete on the particular host machine.

Examples

The following example begins by reporting the distributed ATPG status. It then discontinues all the secondary processes currently running on one host (nemo) and one of the secondary processes running on the other host (ahab):

report_processors

hosts/processors	arch	CPU(s)	%idle	free RAM	process size
ace (primary)	x86	2 x 2.2 GHz	81%	8393.52 MB	20.07 MB
nemo	1 x86	2 x 2.0 GHz	98%	382.33 MB	18.78 MB
	2				18.78 MB
	3				18.78 MB
	4				18.78 MB
ahab	1 x86	1 x 1.7 GHz	99%	334.98 MB	18.78 MB
	2				18.78 MB

Primary process with 6 threads running.

delete_processors nemo ahab:1

```
// Deleted host nemo:4
// Deleted host ahab:1
// Total processors: 1
// Note: Freeing 1 'Tessent FastScan' license.
```

report_processors

hosts/processors	arch	CPU(s)	%idle	free RAM	process size
ace (primary)	x86	2 x 2.2 GHz	81%	8393.52 MB	20.07 MB
ahab	1 x86	1 x 1.7 GHz	97%	229.83 MB	18.78 MB

Primary process with 1 thread running.

delete_read_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Removes the read control line definitions from the specified primary input pins.

Usage

delete_read_controls *primary_input_pin...* | **-All**

Description

The delete_read_controls command deletes read control lines defined with the add_read_controls command. You can delete the read control line definitions for specific pins or for all pins.

Arguments

- *primary_input_pin*
A repeatable string that specifies a list of primary input pins from which you want to delete any read control line definitions.
- **-All**
A switch that deletes the read control line definitions for all primary input pins.

Examples

The following example deletes an incorrect read control line, then redefines that read control line with the correct off-state:

```
add_read_controls 0 r1 r2
delete_read_controls r1
add_read_controls 1 r1
set_system_mode analysis
```

Related Topics

[add_read_controls](#)

[report_read_controls](#)

delete_register_value

Context: all contexts

Mode: setup

Deletes all or a specified register value variable specified with the `add_register_value` command.

Usage

```
delete_register_value {-All | value_name ...}
```

Description

Deletes all or a specified register value variable specified with the [add_register_value](#) command.

Refer to “[Serial Register Load and Unload for LogicBIST and ATPG](#)” in the *Tessent Shell User’s Manual* for complete information.

Arguments

- **-All**
A required switch that deletes all register value variables.
- *value_name* ...
A required repeatable string that deletes a named *value_name*.

Examples

The following example deletes all register value variables:

```
delete_register_value -all
```

Related Topics

[add_register_value](#)

[report_register_value](#)

delete_rtl_to_gates_mapping

Context: all contexts

Mode: setup

Removes name-mapping rules for RTL to post-synthesis/post-layout name mapping.

Usage

```
delete_rtl_to_gates_mapping [-instance_name_map_index instance_name_map_index] |  
    [-register_name_modifiers_index register_name_modifiers_index] |  
    [-port_name_map_index port_name_map_index] |  
    [-port_name_substring_map_index port_name_substring_map_index]
```

Description

Removes the name-mapping rules for RTL to post-synthesis/post-layout name mapping built into the tool or that you previously added using the `add_rtl_to_gates_mapping` command. Use the `report_rtl_to_gates_mapping` command to see the integer index value associated with each mapping.

Arguments

- **-instance_name_map_index *instance_name_map_index***
An optional switch and string pair that specifies the instance renaming rule index to remove.
- **-register_name_modifiers_index *register_name_modifiers_index***
An optional switch and string pair that specifies a mapping previously added by the `add_rtl_to_gates_mapping -register_name_prefix` or `-register_name_suffix` options to remove.
- **-port_name_map_index *port_name_map_index***
An optional switch and string pair that specifies a mapping previously added by the `add_rtl_to_gates_mapping -port_name_map_list` option to remove.
- **-port_name_substring_map_index *port_name_substring_map_index***
An optional switch and string pair that specifies a mapping previously added by the `add_rtl_to_gates_mapping -port_name_substring_map_list` option to remove.

Examples

The following example shows the result of `report_rtl_to_gates_mapping` before and after the `delete_rtl_to_gates_mapping` command was called. The register name prefix "rtlcreg_" which is used to create the built in mapping rule "rtlcreg_%name{[%d]}{.%name{[%d]}}" and the user-specified instance mapping "corea_i1/coreb_i1 -> corea_i1" rules are deleted by using their respective indexes from the report created by the `report_rtl_to_gates_mapping` command.

```
report_rtl_to_gates_mapping
```

```
// Index Register Name Prefix Register Name Suffix
// -----
// 1                                     _reg
// 2          rtlcreg_
// 3
// Index Original instance name Mapped instance name
// -----
// 1      corea_il/coreb_il      corea_il
```

delete_rtl_to_gates_mapping -instance_name_map_index 1

delete_rtl_to_gates_mapping -register_name_modifiers_index 2

report_rtl_to_gates_mapping

```
// Index Register Name Prefix Register Name Suffix
// -----
// 1                                     _reg
// 2
```

Related Topics

delete_scan_chain_families

Context: dft -scan

Mode: analysis

Removes scan chain families.

Usage

```
delete_scan_chain_families {obj_spec | -all} [-force]
```

Description

Use this command to remove scan chain families.

Arguments

- *obj_spec*
An required list that specifies a collection of scan chain families that should be deleted.
- **-all**
An required switch that specifies that all scan chain families that have been added so far should be deleted.

Note

If included in one or more scan mode, you must first delete these modes using the “delete_scan_modes” command.

- **-force**
An optional switch that deletes associated scan modes along with the specified scan chain families.

Related Topics

[get_scan_chain_families](#)

delete_scan_chains

Context: `dft -edt`, `dft -scan`, `dft -test_points`, `patterns -scan`, `patterns -scan_diagnosis`

Mode: setup

Removes the specified scan chain definitions from the scan chain list.

Usage

`delete_scan_chains` *chain_name*... | **-All**

Description

The `delete_scan_chains` command deletes scan chains defined with the `add_scan_chains` command. You can delete the definitions of specific scan chains or of all scan chains.

dft -scan Details

When you remove a scan chain definition, it is only the definition you are removing, not the scan chain itself.

Arguments

- *chain_name*
A repeatable string that specifies the names of the scan chain definitions that you want to delete.
- **-All**
A switch that deletes all scan chain definitions.

Examples

The following example defines several scan chains, adding them to the scan chain list, then deletes one of the scan chains:

```
add_scan_chains chain1 group1 indata2 outdata4
add_scan_chains chain2 group1 indata3 outdata5
add_scan_chains chain3 group1 indata4 outdata6
delete_scan_chains chain2
```

Related Topics

[add_scan_chains](#)

[report_scan_chains](#)

delete_scan_elements

Context: dft -scan, dft -test_points, dft -no_rtl

Mode: setup, analysis

Removes scan elements (such as chain or segment) of a given name.

Usage

delete_scan_elements {*obj_spec* | **-all** }

Description

Use this command to remove scan elements (such as chain or segment) of a given name.

Arguments

- *obj_spec*
A required list that specifies a collection of scan elements that should be deleted.
- **-all**
A required switch that specifies that all scan elements that have been added so far should be deleted.

Note

Only scan elements created by you in the current system mode can be deleted.

Related Topics

[report_scan_elements](#)

delete_scan_groups

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Removes the specified scan chain group definitions from the scan chain group list.

Usage

delete_scan_groups *group_name*... | **-All**

Description

The delete_scan_groups command deletes scan chain groups defined with the add_scan_groups command. You can delete the definitions of specific scan chain groups or of all scan chain groups.

When you delete a scan chain group, the tool also deletes all scan chains within the group.

Arguments

- *group_name*
A repeatable string that specifies the names of the scan chain group definitions that you want to delete.
- **-All**
A switch that deletes all the scan chain group definitions.

Examples

The following example defines two scan chain groups, adding them to the scan chain group list, then deletes one of the scan chain groups:

```
add_scan_groups group1 scanfile1
add_scan_groups group2 scanfile2
delete_scan_groups group1
```

Related Topics

[add_scan_groups](#)

[report_scan_groups](#)

delete_scan_instances

Context: dft -scan, dft -test_points

Mode: setup

Removes the specified, sequential instances from the user-identified scan instance list.

Usage

```
delete_scan_instances -INStances instance_spec | -Modules module_spec | -All |  
-library_models
```

Description

The `delete_scan_instances` command deletes sequential instances, library models or all instances within the specified module that were previously added to the scan instance list by using the `add_scan_instances` command. You can delete either a specific list of instance names or all instances.

You can also use this command to remove an exception status from an instance, that you added using the `add_scan_instances` command, which enabled the tool to convert the instance into a scan cell even though it violated the S4 rule. In this case, although the instance is converted back into a non-scan instance, the effects of its previous unknown state on downstream instances is not reset.

User-identified scan instances result from using the `add_scan_instances` command.

If you issue an `insert_test_logic` command after removing an instance from the user-identified scan list with the `delete_scan_instances` command, the tool then has the option of including it in the system-identified scan instance list.

Arguments

- `-INStances instance_spec`
An optional switch and value pair that causes to tool to delete the specified instances from the user-identified scan instance list. *instance_spec* can be a Tcl list of one or more instances or a collection of one or more instances. If the instance is hierarchical, then all instances beneath it are also deleted from the user-identified scan instance list.
- `-Modules module_spec`
An optional switch and value pair that causes to tool to delete all instances within the specified modules from the user-identified scan instance list. *module_spec* can be a Tcl list of one or more modules or a collection of one or more modules. Note: module may specify the name of a Verilog module, or a Tessent library model.
- `-All`
An optional switch that specifies to delete all instances from the user-identified scan instance list. This switch does not affect the instances in the system-identified scan instance list.

- `-library_models`

An optional switch that causes the tool to delete all `nonscan_instances` that were marked as such by using the `-module` switch followed by a Tessent library model name. This switch serves as a replacement for the obsolete “`delete_(non)scan_models -all`” command.

Examples

The following example deletes an extra sequential scan instance that was defined to be treated as a scan cell; thus, the deleted instance is no longer included in the user-identified scan instance list:

```
add_scan_instances -instances i_1006 i_1007 i_1008  
delete_scan_instances i_1007
```

delete_scan_modes

Context: dft -scan

Mode: analysis

Removes one or more scan modes.

Usage

delete_scan_modes {*obj_spec* | **-all**}

Description

Use this command to remove one or more chain scan modes.

Arguments

- *obj_spec*
An required list of scan modes that should be deleted.
- **-all**
An required switch that specifies that all scan modes that have been added so far should be deleted.

Related Topics

[add_scan_mode](#)

[get_scan_modes](#)

delete_schematic_callout

Context: all contexts

Mode: all modes

Deletes informational callouts from a Tessent Visualizer schematic window.

Usage

```
delete_schematic_callout object_spec [-display window_name]
```

Description

Deletes informational callouts from objects in the Tessent Visualizer schematic window.

Arguments

- *object_spec*
A Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, gate_pin, instance, or net objects.
- -display *window_name*
An optional switch and literal that specifies the Tessent Visualizer schematic window from which to delete the callout. The valid options for the *window_name* argument are as follows:
 - flat_schematic — A literal that specifies the Flat Schematic window.
 - hierarchical_schematic — A literal that specifies the Hierarchical Schematic window.By default, the callout is deleted from the Flat Schematic window.

Examples

This example shows how to add a callout with the message “this is an instance” to a gate and another callout with the message “this is a pin” to a pin in the Hierarchical Schematic window. After these are added, the callout for the pin is deleted.

```
add_schematic_callout U_0/CSEEBblock/rootcntr_reg[1] U_0/CSEEBblock/rootcntr_reg[1]/Q \  
-message "this is an instance" -display hierarchical_schematic
```

```
add_schematic_callout U_0/CSEEBblock/rootcntr_reg[1]/Q -m "this is a pin" \  
-display hierarchical_schematic
```

```
delete_schematic_callout U_0/CSEEBblock/rootcntr_reg[1]/Q -display hierarchical_schematic
```

delete_schematic_objects

Context: all contexts

Modes: all modes

Deletes design objects from a Tessent Visualizer schematic window.

Usage

```
delete_schematic_objects [object_spec | -all] [-display {flat_schematic |  
  hierarchical_schematic}]
```

Description

Delete objects from the specified schematic window.

Arguments

- *object_spec*
A Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, gate_pin, instance, or net objects.
- *-all*
Remove all objects from the schematic window. Mutually exclusive with *object_spec*
- *-display window_name*
An optional switch and literal that specifies the Tessent Visualizer schematic window from which to delete the objects. The valid options for the *window_name* argument are as follows:
 - flat_schematic* — A literal that specifies the Flat Schematic window.
 - hierarchical_schematic* — A literal that specifies the Hierarchical Schematic window.By default, the objects are deleted from the Flat Schematic window.

Examples

Example 1

This example shows how to delete a collection of objects from the Hierarchical Schematic window:

```
delete_schematic_objects { bsr_i1 bsr_i2 } -display hierarchical_schematic
```

Example 2

This example shows how to delete all objects from the Flat Schematic window:

```
delete_schematic_objects -all
```

delete_schematic_path

Context: all contexts

Mode: all modes

Delete the specified path from a Tessent Visualizer schematic window.

Usage

```
delete_schematic_path object_spec [-display window_name]
```

Description

Deletes the specified path from the Tessent Visualizer Flat or Hierarchical Schematic window.

Arguments

- *object_spec*
A Tcl list or Tcl collection of one or more names of pin or gate_pin objects. Given lists of pins must represent existing connections in the hierarchical or flat data model.
- -display *window_name*
An optional switch and literal that specifies the Tessent Visualizer schematic window from which to delete the path. The valid options for the *window_name* argument are as follows:
 - flat_schematic — A literal that specifies the Flat Schematic window.
 - hierarchical_schematic — A literal that specifies the Hierarchical Schematic window.By default, the path is deleted from the Flat Schematic window.

Examples

This example shows how to delete a path from the Hierarchical Schematic window:

```
delete_schematic_path { U_0/CSEBlock/rootcntr_reg[1]/Q U_0/CSEBlock/U50/A0 } \  
-display hierarchical_window
```

delete_simdut_fault

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Removes the injected stuck-at fault at the specified signal or all the injected faults.

Usage

`delete_simdut_fault {-signal signal_name / -all}`

Description

Removes the injected stuck-at fault at the specified signal or all the injected faults.

Arguments

- **-signal *signal_name* / -all**

A required choice, as follows:

-signal *signal_name*: deletes the specified injected stuck-at fault at the specified signal.

-all: deletes all of the injected faults stored in the simulator.

Examples

The following example removes an injected stuck-at fault from the `SIMDUT_TB.DUT_inst.memory00.q_a` signal.

```
delete_simdut_fault -signal SIMDUT_TB.DUT_inst.memory00.q_a
```

Related Topics

[add_simdut_fault](#)

[report_simdut_faults](#)

delete_simulation_contexts

Context: all contexts

Mode: setup, analysis

Prerequisite: A flat model must currently exist

Deletes one or more user-defined simulation contexts.

Usage

```
delete_simulation_contexts {context_name... | -all_user_defined}
```

Description

Deletes one or more user-defined simulation contexts.

The `delete_simulation_contexts` command enables you to delete one or multiple or all user-defined simulation contexts.

Arguments

- ***context_name***
A required string that defines the name of one or more simulation contexts. Note that you cannot use wildcard characters in the ***context_name***. You also cannot delete any of the predefined context names listed in [Table 6-8](#) on page 2291.
- **-all_user_defined**
A required switch that specifies all user-defined simulation contexts.

Examples

Example 1

The following example lists all of the user-defined simulation contexts and then deletes them:

```
SETUP> get_simulation_context_list -user_defined {myContext1 myContext2 myContext3}  
SETUP> delete_simulation_contexts -all_user_defined  
SETUP> get_simulation_context_list -user_defined { }
```

Example 2

The following example lists all of the user-defined simulation contexts and then deletes two of them:

```
SETUP> get_simulation_context_list -user_defined {myContext1 myContext2 myContext3}  
SETUP> delete_simulation_contexts { myContext2 myContext3 }  
SETUP> get_simulation_context_list -user_defined { myContext1 }
```

delete_simulation_forces

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Removes forces from one or more gate_pin objects.

Usage

```
delete_simulation_forces {obj_spec | -all}
```

Description

Removes forces from one or more gate_pin objects.

The delete_simulation_forces command removes simulation forces from the specified gate_pin object(s). When this command removes a simulation force, the tool immediately propagates the values on the driving gate_pin objects to keep the circuit in a consistent state.

This command is permitted for user-defined contexts only.

Arguments

- *obj_spec*
A required value that specifies one or more gate_pin objects.
- **-all**
A required switch that removes all simulation forces on all gate_pin objects within the current simulation context.

Examples

The following example shows the effect of adding a force and then removing all forces:

```
ANALYSIS> set_current_simulation_context myContext
ANALYSIS> add_simulation_forces [get_gate_pins I1] -value 1
ANALYSIS> report_simulation_forces
```

```
Value  Object
-----  -----
1      I1
```

```
ANALYSIS> delete_simulation_forces -all
ANALYSIS> report_simulation_forces
```

delete_synchronous_clock_group

Context: dft, patterns

Mode: setup

Removes one or more user-defined synchronous clock groups.

Usage

```
delete_synchronous_clock_group { object_spec | -all } [-scope {capture | shift | all}]
```

Note

 Synchronous clock groups have no impact on scan chain analysis, test point identification, and EDT IP insertion (in the dft -scan, dft -test_points and dft -edt sub-contexts).

Description

Removes one or more user-defined synchronous clock groups.

The `delete_synchronous_clock_group` command removes clock groups that you defined with the `add_synchronous_clock_group` command. For more information about synchronous clock groups, refer to the [add_synchronous_clock_group](#) command.

Arguments

- ***object_spec***
A Tcl list or collection of pin or net objects that specify a current synchronous clock group. You must specify the complete original `object_spec` for the clock group you want to remove.
- **-all**
A switch that specifies all synchronous clock groups.
- **-scope {capture | shift | all}**
An optional switch and literal pair that specifies whether to delete capture clock groups, shift clock groups, or both. By default, capture clock groups are deleted.

Examples

The following example creates two synchronous clock groups and then removes one of them:

```
SETUP> report_clocks
```

```
User-defined Clocks (4):
=====

Sync and Async Source Clocks
=====
-----
Name   Off State  Constraints  Internal
-----
I1      0          No           No
I2      0          No           No
I3      0          No           No
I4      0          No           No
```

```
SETUP> add_synchronous_clock_group {I1 I2}
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Group
=====
// No.  Clocks (Labels)  Scope
// ---  -
// 1    I1                capture
//      I2
```

```
SETUP> add_synchronous_clock_group {I3 I4}
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Groups
=====
// No.  Clocks (Labels)  Scope
// ---  -
// 1    I1                capture
//      I2
// 2    I3                capture
//      I4
```

```
SETUP> delete_synchronous_clock_group {I1}
```

```
// Error: Specified synchronous clock group does not exist.
```

```
SETUP> delete_synchronous_clock_group {I2 I1}
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Group
=====
// No.  Clocks (Labels)  Scope
// ---  -
// 1    I3                capture
//      I4
```

The following example uses the same clocks to create a synchronous clock group for both capture and shift and then removes the capture group:

```
SETUP> delete_synchronous_clock_group -all -scope all
SETUP> add_synchronous_clock_group -scope all {I1 I2}
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Group
=====
// No.  Clocks (Labels)  Scope
// ---  -
//   1   I1                capture
//       I2
// ---  -
//   1   I1                shift
//       I2
```

SETUP> delete_synchronous_clock_group -all

// All user-defined synchronous clock groups in the scope of capture are deleted.

SETUP> report_synchronous_clock_groups

```
User-defined Synchronous Clock Group
=====
// No.  Clocks (Labels)  Scope
// ---  -
//   1   I1                shift
//       I2
```

delete_test_points

Context: dft -test_points

Mode: setup

Removes the specified test point definitions.

Usage

```
delete_test_points {object_spec | -location pin/port_spec | -all} [-silent]
```

Description

You can use this command to delete all test points, specific test points from a `test_point` object spec as returned from the [get_test_points](#) command, or specific test points according to their location. This command removes both user-defined and system-defined test points.

Arguments

- *object_spec*
The value of `object_spec` can be a control point or observe point or a Tcl list or Tcl collection of one or more test points as returned from the [get_test_points](#) command.
- -location *pin/port_spec*
A switch and string pair that specifies a pathname to the test points to delete. *pin/port spec* can be a Tcl list of one or more pins/ports, or a collection of one or more pin/port objects.
- -all
A switch that removes the control and observe test points from all locations.
- -silent
An optional switch that suppresses the error message normally generated when the command does not result in the deletion of any test points. The error message is intended to indicate a possible mistake when specifying patterns. This -silent option has no effect on any other error reporting.

Note

 You can use the -silent switch to manage the case in which no test_points are deleted. Before using the -silent switch for this purpose, refer to the `set_tcl_shell_options -change_no_result_warnings_to_errors` switch description for detailed usage.

Examples

Example 1

The following example removes specified test points:

```
delete_test_points -location {/I_6_16/cp /I_7_16/q}
```

The `delete_test_points` command only specifies the pathnames of the test points, not the type. This example includes both control and observe test points and deletes them by default.

Example 2

The following example removes all observe points returned by the `get_test_point_type` command:

```
delete_test_points [get_test_points -type OP]
```

delete_tied_signals

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Removes the assigned (tied) value from the specified floating nets or pins.

Usage

delete_tied_signals {*floating_object_name*... | **-All**} [-Pin]

Description

The delete_tied_signals command deletes the tied values assigned with the add_tied_signals command. You can display a list of tied signals using the report_tied_signals command.

Whenever you delete tied values from nets or pins, be sure to re-add any necessary values before performing another simulation. If you do not add required tied values to floating nets or pins, the tool displays a warning. The warning states that the design has floating nets or pins and assumes they are tied to the default value; you must set the default value using the set_tied_signals command.

Arguments

- *floating_object_name*
A repeatable string that specifies the names of the tied floating nets or pins whose tied values you want to delete.
If you do not specify the -Pin option, the tool assumes *floating_object_name* is a net name. If you specify the -Pin option, it assumes the *floating_object_name* is a pin name.
- **-All**
A switch that deletes the tied values from all tied floating nets or pins.
- **-Pin**
A switch specifying that the *floating_object_name* argument that you provide is a floating pin name.

Examples

The following example deletes the tied value from the user-class tied net “vcc”; thereby leaving “vcc” as a floating net:

```
add_tied_signals 1 vcc vdd
delete_tied_signals vcc
```

Related Topics

[add_tied_signals](#)

[report_tied_signals](#)

[set_tied_signals](#)

delete_wave_generator_pins

Context: all

Mode: all

Deletes provided pin objects, or all objects, from the Tessent Visualizer Wave Generator tab.

Usage

```
delete_wave_generator_pins object_spec | -all
```

Description

A flat model must be available to use this command.

Arguments

- *object_spec*
A Tcl list or Tcl collection of one or more names of pin, port, pseudo_port, or gate_pin objects.
- -all
An optional switch that specifies that all pins are deleted from the Wave Generator tab.

Examples

```
delete_wave_generator_pins {inst/clk inst/scan_en}
```

```
delete_wave_generator_pins -all
```

delete_write_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Removes the write control line definitions from the specified primary input pins.

Usage

delete_write_controls *primary_input_pin...* | **-All**

Description

The delete_write_controls command deletes write control lines defined with the add_write_controls command. You can delete the write control line definitions for specific pins or for all pins.

Arguments

- *primary_input_pin*
A repeatable string that specifies a list of primary input pins from which you want to delete any write control line definitions.
- **-All**
A switch that deletes the write control line definitions for all primary input pins.

Examples

The following example deletes an incorrect write control line, then re-adds that write control line with the correct off-state:

```
add_write_controls 0 w1 w2
delete_write_controls w1
add_write_controls 1 w1
set_system_mode analysis
```

Related Topics

[add_write_controls](#)

[report_write_controls](#)

diagnose_failures

Context: patterns -scan_diagnosis

Mode: analysis

Prerequisites: The [read_patterns](#) command must be set to a pattern source.

Diagnoses the failures in the specified failure file.

Usage

```
diagnose_failures {failure_filename | -Internal} [-Output report_filepath | >  
  pipe_to_filename] [-Csv csv_filename] [-Replace] [-Faulty_chain {faulty_chain_name  
  faulty_chain_type}...]
```

Description

The `diagnose_failures` command performs a diagnosis of the failing scan and chain test patterns in the specified failure file, or diagnosis of the IDDQ patterns in the specified failure file.

For scan and chain test patterns, you must translate the ATE failure log into a failure file as described in the “[Guidelines for Preparing the ATE Failure File](#)” section in the *Tessent Diagnosis User’s Manual*. For IDDQ patterns, refer to “[IDDQ Diagnosis](#)” for the required failure file format.

It is critical that the data in the test patterns, flattened netlist, and failure file be synchronized for diagnosis. For more information, refer to “[Input File Requirements](#)” in the *Tessent Diagnosis User’s Manual*.

For complete information on running diagnosis and interpreting the results, refer to the *Tessent Diagnosis User’s Manual*.

Note

 The following warning message displays when the flat model contains some timing exceptions and the static timing exception analysis data is not available in the flat model and needs to be re-analyzed:

```
// Warning: The flat model does not include static timing exception  
analysis data because it was saved before the create_patterns command.  
This can result in longer diagnosis run times. Suggest using the flat  
model that includes static timing exceptions analysis to improve diagnosis  
time.
```

Arguments

- *failure_filename*

A required string that specifies the name of the file that contains the failing test pattern information for diagnosis. This file can use either the pattern-based or cycle-based format as described in the “[Guidelines for Preparing the ATE Failure File](#)” section in the *Tessent Diagnosis User’s Manual*.

For IDDQ diagnosis, specify the IDDQ failure file. Refer to “[IDDQ Diagnosis](#)” for more information.

- **-Internal**

An required switch that directs the tool to use the in-memory failure file. You must issue a [read_failures](#) command before you use the `diagnose_failures -internal` command. Refer to “[Diagnosis Improvements and Retrieving Internal Scan Cell Information](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

- `-Output report_filepath | > pipe_to_filename`

An optional choice that directs the tool to write the diagnostic report in ASCII format to the specified file. By default, the diagnostic report displays on screen.

`-Output report_filepath`: An optional switch and string pair that specifies the output file. This option adds the physical layout information to the report. The physical layout information is not included in the transcript.

`> pipe_to_filename`: An optional redirection operator and string pair that specifies the output file. Choose this option when you have specified `set_diagnosis_options -internal_failing_cells` on. The internal failing cell data is only reported to the transcript unless you redirect it to a file; however, the `-output` switch does not include the internal failing cell data in its report. Refer to “[Internal Scan Cell Profiling for Compressed Patterns](#)” for more information.

- `-Csv filename`

An optional switch and string pair that directs the tool to write the diagnostic report in Comma Separated Value (CSV) format to the specified file. The CSV format does not include the list of failing patterns for each symptom. By default, the diagnostic report displays on screen.

- `-Replace`

An optional switch that directs the tool to overwrite existing diagnostic report files in either ASCII or CSV format. By default, the tool does not overwrite existing files.

- `-Faulty_chain faulty_chain_name faulty_chain_type`

An optional switch and repeatable string and literal pair that enables you to run diagnosis on specified chain failures in addition to the scan failures contained in a failure file.

`faulty_chain_name` — string that specifies the name of the faulty chain.

`fault_type` — literal that specifies the fault type associated with the faulty chain. Valid fault types include:

STUCK_AT_1
STUCK_AT_0
SLOW_TO_FALL
SLOW_TO_RISE
SLOW

FAST_TO_RISE

FAST_TO_FALL

FAST

INDETERMINATE — specifies the fault type cannot be determined.

Examples

Example 1

The following example: sets *pattern_file1* as the external test pattern source, injects a stuck-at-0 fault into the design, writes out a failure file named *fail_patterns*, and performs a diagnosis of the failing patterns in the *fail_patterns* file.

```
set_system_mode analysis  
read_patterns pattern_file1  
write_failures fail_patterns i_1006/i1 -stuck_at 0  
  
// failing_patterns=9 simulated_patterns=36 simulation_time=0.00 sec  
  
diagnose_failures fail_patterns  
  
...
```

Still using the external test pattern source file *pattern_file1*, the following example: injects an additional stuck-at-0 fault into the *fail_patterns* failure file, performs a diagnosis of the failing patterns in the *fail_patterns* file, and sends the report to a file named *fail_diags*.

```
write_failures fail_patterns i_1005/i1 -stuck_at 0 -replace  
  
// failing_patterns=4 simulated_patterns=36 simulation_time=0.00 sec  
  
diagnose_failures fail_patterns -output fail_diags
```

Example 2

The following example loads patterns from two files into the tool external pattern database and performs two separate diagnoses using the default settings. The example writes the resulting reports to files instead of displaying them onscreen. The failure file, *scan_failure_file*, contains only a scan test section (“*scan_test*” keyword followed by scan test fails), so the tool performs only a scan diagnosis for that file. The second file, *chain_failure_file*, contains a chain test section (“*chain_test*” keyword followed by chain test fails) as well as a scan test section. The tool performs only a chain diagnosis for that file.

```
read_patterns pat_file1  
read_patterns pat_file2 -append  
diagnose_failures scan_failure_file -output scan_diag.ascii -csv scan_diag.csv  
diagnose_failures chain_failure_file -output chain_diag.ascii -replace
```

Example 3

The following example first performs chain diagnosis on a failure file that contains a *chain_test* section. The example next attempts a diagnosis of a failure file that contains no *chain_test* data;

however, because the `set_diagnosis_options` command is set to chain mode, the tool skips this diagnosis.

```
read_patterns pat_file1  
set_diagnosis_options -mode chain  
diagnose_failures chain_failure_file -output chain_diag.ascii -replace  
diagnose_failures scan_only_failure_file -output scan_diag.ascii -csv scan_diag.csv  
  
// Error: Cannot identify faulty chains. Please either use chain test  
// patterns or specify faulty chains.
```

Example 4

The following example sets the external test pattern source to *pattern_file1*, runs diagnosis on the `chain_foo` chain failure and the failed patterns failure file and runs diagnosis on the `chain_foo` chain failure and the *failed_cycles* failure file.

```
set_system_mode analysis  
read_patterns pattern_file1  
diagnose_failures failed_cycles -faulty_chain chain_foo FAST_TO_FALL
```

[write_failures](#)

display_diagnosis_report

Context: patterns -scan_diagnosis

Mode: analysis

Prerequisites: This command can only operate on a diagnosis report file written with the [diagnose_failures](#) command with the -Output switch.

Opens a diagnosis report in which you can click symptoms and suspect locations to add related gates to the Tessent Visualizer Hierarchical Schematic window.

Usage

display_diagnosis_report *diagnose_failures_output_filename*

Tessent Visualizer Menu Path: Open > Diagnosis Report Viewer

Description

The display_diagnosis_report command opens the specified diagnosis report file in the Diagnosis Report Viewer of Tessent Visualizer. In the displayed report, each symptom and all suspect locations (pin and net pathnames) show up as active links. Clicking a suspect's pin_pathname link adds the gate associated with that pin to the Tessent Visualizer Hierarchical Schematic window. Clicking a suspect's net_pathname link adds all the gates connected to that net. Clicking a symptom link adds all the gates with pins in that symptom's suspect list.

Refer to “[Diagnosis Reporting](#)” in the *Tessent Diagnosis User's Manual* for a detailed description of the types of information contained in the diagnosis report.

Arguments

- *diagnose_failures_output_filename*
A required string that specifies the pathname of a diagnosis report file written out using the diagnose_failures -Output command.

Examples

The following example performs scan diagnosis using the set of ATPG patterns in the pattern file *pat_file1* and the failure information in the failure file *scan_failure_file*, writing the diagnosis report in ASCII format to the file *scan_diag.ascii*. The example then opens Tessent Visualizer if it is not already open and opens the diagnosis report in the Diagnosis Report Viewer.

```
read_patterns pat_file1  
diagnose_failures scan_failure_file -output scan_diag.ascii -replace  
display_diagnosis_report scan_diag.ascii
```

Related Topics

[diagnose_failures](#)

[set_diagnosis_options](#)

display_message

Context: unspecified, all contexts

Mode: all modes

Sends a message to the specified message stream.

Usage

display_message *string* [-error | -warning | -info | -note | -screen_only] [-abort]

Description

The string can contain \n to break the message into multiple lines. The tool prefixes messages sent in the message stream with an “// Error: ”, “// Warning:” , “//” , “//” or “//Note:” string as appropriate, and automatically indents successive lines remaining.

The output of Tcl commands such as “puts” redirects to the screen, to a log file, or both as with any other tool output.

Arguments

- *string*
A required string that specifies the message to be sent to the message stream. The string supports the use of the newline character sequence “\n” to break the message into multiple lines. The first character of the string must be something other than a dash (“-”) character.
- -error
An optional literal that specifies to send a message into the error stream. This message does not interrupt the execution of the script. You can issue multiple error messages and then terminate the script using a {return -code error “string”} command. This return code causes the dofile to abort unless you specify [set_dofile_abort](#) off or the -abort switch to the display_message command.
- -warning
An optional literal that specifies to display a warning.
- -info
An optional literal that specifies to display an information note. The message has a double slash “//” prefix.
- -note
An optional literal that specifies to display a note.
- -screen_only
An optional Boolean switch that specifies that the message string is for the transcript window only.

When specified, the string is not sent to the log file as it normally does and it suppresses the new line character at the end of the string. When using the -screen_only switch, you use

display_message

explicit “\n” characters to force the new string to appear on a new line. You can also use the “\r” character at the beginning of the string to bring back the cursor to the beginning of the line and overwrite the existing string on the screen. Using the “\r” character is useful when you want to echo a progress status message on the screen. When you do that, make sure the new string is as long as the original string that was displayed on the line; otherwise, the string contains leftover characters from the previous string.

- -abort

An optional switch that forces the tool to exit.

Examples

The following example issues two error messages and then stops the invocation of the current Tcl command using a Tcl return -code error command.

```
display_message “this value is wrong” -error  
display_message “this other value is also wrong” -error  
return -code error
```

[unregister_tcl_command](#)

display_specification

Context: dft

Mode: setup, analysis

Displays the `DftSpecification(design_name,id)` configuration data in a tab of the Configuration Tree Visualizer window.

Usage

```
display_specification [id] [-design_name design_name] [-create]
```

Description

Displays the `DftSpecification(design_name,id)` configuration data in a tab of the Configuration Data Visualizer window.

You can create a `DftSpecification` from scratch in the Configuration Data Visualizer by using the `-create` option, or also modify an existing `DftSpecification`.

When only one `DftSpecification` wrapper is defined in memory, you do not need to supply any arguments; the tool automatically displays the single `DftSpecification` wrapper.

You define or modify a `DftSpecification` using the Data Configuration Visualizer window. This window provides a graphical user interface for inserting Tessent DFT IP into existing designs. For information on using the Configuration Data Visualizer, refer to the section “[How to Edit or Modify a DftSpecification](#)” in the *Tessent IJTAG User’s Manual*.

Arguments

- *id*
An optional string that specifies the `DftSpecification` wrapper to be displayed. As described in the `DftSpecification` wrapper syntax, the wrapper is identified by the two strings `design_name` and `id`. If you only have one `DftSpecification` wrapper present in memory that matches `DftSpecification(design_name,*)`, you can omit the `id` from the `display_specification` command. However, if several `DftSpecification` wrappers matching `DftSpecification(design_name,*)` exist in memory, you must specify the appropriate `id` when running the `display_specification` command. Refer to the description of the `-design_name` option to understand how the value of `design_name` is obtained.
- `-design_name design_name`
An optional switch and string pair that specifies the `design_name` value used to identify the `DftSpecification` wrapper. The `-design_name` value defaults to the current design if it has been set with the `set_current_design` command. If the current design has not been set, it is extracted from the `DftSpecification` wrapper existing in memory.

When the `id` is specified, if exactly one wrapper matches “`DftSpecification (*,<id>)`” in memory, the `design_name` is extracted from the `design_name` parameter of the `DftSpecification` wrapper; if more than one wrapper matches, the `-design_name` must be

specified unless the `-create` option is specified. When the `id` is not specified, if exactly one wrapper matches “DftSpecification (*,*)” in memory, the `design_name` is extracted from the `design_name` parameter of the DftSpecification wrapper; if more than one wrapper matches, the `-design_name` must be specified.

- `-create`

An optional switch that turns off the existence check of the DftSpecification wrapper and specifies to create and display an empty DftSpecification wrapper. If either of the `id` or `-design_name` options are not specified, their values are determined using the heuristic described in the `id` and `-design_name` options description. If the tool cannot determine the `id`, the default is “rtl” in the `dft -rtl` context and “gate” in the `dft -no_rtl` context. If the tool cannot determine the `design_name`, it sets it to “?” in the created file, which you can then modify in the Data Configuration Visualizer. If you do not change the “?” to a valid design name, the tool generates an error when you attempt to process the DftSpecification.

Examples

Example 1

The following example reads a DftSpecification from a file and displays it in the Configuration Data Visualizer.

```
set_context dft -rtl
read_config_data ./my_design.dft_spec_rtl
display_specification
```

Example 2

The following example creates an empty DftSpecification and displays it in the Configuration Data Visualizer, enabling you to add content using that graphical user interface. The created DftSpecification wrapper is named “DftSpecification(mydesign,rtl)”. The *design_name* is taken from the name of the current design. The *id* defaults to “rtl” because the command was called inside the `dft -rtl` context.

```
set_context dft -rtl
read_verilog mydesign.v
set_current_design mydesign
display_specification
```

[process_dft_specification](#)

dofile

Context: unspecified, all contexts

Mode: all modes

Runs the commands contained within the specified file.

Usage

dofile *filename* [-History]

Description

The dofile command sequentially runs the commands contained in a specified file. This command is especially useful when you must issue a series of commands. Rather than running each command separately, you can place them into a file in the required order and then run them by using the dofile command. You can also place comment lines in the file by starting the line with a double slash (//); the tool handles these lines as comments and ignores them.

The dofile command sends each command expression (in order) to the tool, which in turn displays each command line from the file before running it. If the tool encounters an error due to any command, the dofile command stops its execution, and displays an error message. You can enable the dofile command to continue regardless of errors by setting the `set_dofile_abort` command to Off.

The dofile command is very similar to the Tcl source command except the dofile command has the following additional usability features:

- Loads relative paths called with dofile <RelativeFilePath> relative to the position of the dofile containing the dofile command.

You must use the same syntax when using the source command as shown here: `source [file dirname [info script]]/<RelativePathToFile>`. When the source command is used, the file is processed purely by the Tcl shell.

- Accepts // as comments, as well as #.
- Automatically escapes [#] and [#:#] entries in bus names.

Arguments

- *filename*
A required string that specifies the name of the file that contains the commands that you want the tool to run.
- -History
An optional switch that specifies for the tool to add the commands from a dofile to the command line history list. By default, the commands in a dofile are not inserted into the history list, but the dofile command itself is added to the list.

Examples

The following example runs, in order, all the commands from the file *command_file*:

dofile command_file

The *command_file* may contain any Tcl or application command available. An example of a *command_file* is as follows:

```
foreach_in_collection net [get_nets u1/*] {
    if {[sizeof_collection [get_fanins $net]] == 0} {
        delete_connections [get_fanouts $net -stop_on pin]
        delete_nets $net
    }
}
```

Chapter 4

Command Dictionary (E - Q)

The Command Dictionary describes the application commands for Tessent Shell. For quick reference, the commands appear alphabetically with each beginning on a separate page.

The command usage line syntax conventions are common to all products documented in this manual.

Table 4-1. Conventions for Command Line Syntax

Convention	Example	Usage
UPPercase	-Static	Required argument letters are in uppercase; in most cases, you may omit lowercase letters when entering literal arguments, and you need not enter in uppercase. Arguments are normally case insensitive.
Boldface	set_your_mode mode1 mode2	A boldface font indicates a required argument.
[]	exit [-force]	Square brackets enclose optional arguments. Do not enter the brackets.
<i>Italic</i>	dofile <i>filename</i>	An italic font indicates a user-supplied argument.
{ }	add_your_paths { <i>path_name</i> -All} [-max_paths <i>number</i>]	Braces enclose arguments to show grouping. Do not enter the braces.
	add_your_paths { <i>path_name</i> -All} [-max_paths <i>number</i>]	The vertical bar indicates an either/or choice between items. Do not include the bar in the command.
Underline	set_your_switch <u>ON</u> OFF	An underlined item indicates either the default argument or the default value of an argument.
...	add_your_clock <i>off_state</i> <i>pin_list</i> ...	An ellipsis follows an argument that may appear more than once. Do not include the ellipsis when entering commands.

Command Descriptions

This section describes commands, alphabetically from E through Q, that available in Tessent Shell. The beginning of each command description shows the contexts and modes that support the command and provides the following information:

Context: Lists each context and sub-context that supports the command. “All contexts” means that the command is supported in all available contexts. “Unspecified” means that you do not have to set a context to use the command.

Mode: Lists each mode that supports the command. “All modes” means that the command is supported in all available modes. In some cases, a particular mode supports the command only within certain contexts, and this is noted in parentheses after the mode type.

Table 4-2. Commands E Through Q

Command	Description
echo	Issues a user-defined string to the transcript.
elaborate_icl_modules	Elaborates the specified ICL modules.
encrypt_layout	Encrypts a layout database (LDB) for purposes of data transfer.
execute_cdp_test	Runs the specified test using the currently connected tester.
execute_gpib_command	Enables you to control and program GPIB equipment.
execute_tester_command	Enables you to verify and debug the wiring connection between an adaptor used for Tessent SiliconInsight and the design under test.
exit	Terminates the application tool program.
expand_compressed_patterns	Expands compressed 1-hot patterns for better internal failing flop diagnosis.
extract_fault_sites	Extracts interconnect bridges and opens from a layout database and writes out the data in UDFM file format.
extract_icl	Checks the ICL connectivity rules between IJTAG instances, extracts the top-level ICL module, creates an SDC file that can be used for synthesis and static timing analysis (STA), and extracts an IJTAG graybox model.
extract_inter_cell_data	Extracts neighborhood cell combinations and writes the combinations out in UDFM file format.
extract_sdc	Creates an SDC file that can be used for synthesis and static timing analysis (STA).
filter_collection	Filters a previously created collection, resulting in a new collection.

Table 4-2. Commands E Through Q (cont.)

Command	Description
find_design_names	Displays design object hierarchical names matched by an input string, which may include asterisk (*) or question mark (?) wildcard characters.
foreach_in_collection	Iterates over each element in a collection.
format_dictionary	Generates a Tcl dictionary in a human-readable format.
get_attribute_list	Returns an alphabetically sorted Tcl list of attribute names.
get_attribute_option	Retrieves the current setting of an attribute's option.
get_attribute_value_list	Retrieves the value of an attribute on the specified design objects.
get_attributed_objects	Retrieves the complete collection of objects matching one of the specified object type lists and having one of the attributes found in the <i>attribute_name_list</i> specified on the object.
get_auxiliary_pins	Returns the input or output data or enable auxiliary pins associated to ports
get_boundary_scan_port_option	Returns the cell_options defined on the specified port, or the specified pin_order_file name, or the pad_io_ports collection.
get_bundle_objects	Returns a collection of bundle/leaf objects in the current design specified by the name_patterns list in conjunction with the specified options. Those bundle (leaf in case of descendants) objects are ancestors or descendants of the objects that match the specified <i>name_patterns</i> depending upon the specified options.
get_capture_timing_option	Returns specific capture timing options specified with the set_capture_timing_options command.
get_cdp_test_data	Returns requested information for a specific CDP test.
get_cdp_test_list	Returns a Tcl list of tests currently available in the CDP.
get_clock_option	Returns the setting of an option specified with the add_clocks command.
get_clocks	Returns a collection of user clocks based on filters you specify.
get_common_parent_instance	Returns the common ancestor of all instances, pins, or nets found in <i>object_spec</i> .
get_config_elements	Returns a collection of configuration elements or a count of configuration elements when the -count option is used.

Table 4-2. Commands E Through Q (cont.)

Command	Description
<code>get_config_messages</code>	Returns a list of message strings attached to a configuration element.
<code>get_config_selected_nodes</code>	Returns a collection containing the configuration elements corresponding to the tree nodes currently selected in the Configuration Data Visualizer.
<code>get_config_value</code>	Returns a value associated with a configuration element based on the specified option.
<code>get_context</code>	Introspects the current context.
<code>get_current_design</code>	Returns a collection of one element that specifies the top-level design when previously set.
<code>get_current_mode</code>	Returns the current test mode, as specified by the <code>set_current_mode</code> command.
<code>get_current_physical_block</code>	Returns the current physical block specified with the <code>set_current_physical_block</code> command.
<code>get_current_silicon_insight_setup</code>	Returns the currently selected SiliconInsight setup as specified in the TSI setup spec.
<code>get_current_simulation_context</code>	Returns the name of the current simulation context.
<code>get_default_ssn_datapath_configuration</code>	Retrieves an override setting of an ICL primary target on a SSN datapath.
<code>get_defaults_value</code>	Obtains the default value of a property as specified in one of the DefaultsSpecification(company user group)/DftSpecification or DefaultsSpecification(company user group)/PatternsSpecification wrappers.
<code>get_design_level</code>	Returns the design level previously defined with the <code>set_design_level</code> command.
<code>get_design_objects</code>	Returns a collection of design objects associated to the <code>object_ids</code> supplied.
<code>get_design_sources</code>	Returns the pathnames or file extensions previously specified with the <code>set_design_sources</code> command.
<code>get_dfm_rules</code>	Returns a TCL list of the DFM rules contained in the layout database.
<code>get_dft_cell</code>	Retrieves the named sets of cells to use when test hardware must be inserted (as a Tcl list of the currently available cell selection names), or a particular cell given the name and required cell function of a specified set of cells.

Table 4-2. Commands E Through Q (cont.)

Command	Description
get_dft_cell_selection_mapping	Returns the library cell selection associated to the specified power domain.
get_dft_info_dictionary	Creates a Tcl dictionary containing the information about the DFT inserted in the RTL that must be considered during scan insertion.
get_dft_signal	Obtains the source of a DFT signal or various aspects about the DFT signal.
get_dft_signals_option	Returns the current setting specified by the <code>set_dft_signals_options</code> command.
get_dft_specification_requirement	Returns the requirements set using the <code>set_dft_specification_requirements</code> command.
get_drc_handling	Retrieves the DRC handling status for the DRC with the specified name.
get_equivalent_editable_node	Checks if a node is editable. If the node is not editable, then returns the node's editable equivalent node if it exists.
get_fanins	Returns a collection of all requested objects found in the fan-in of the specified pin, net, or port object.
get_fanouts	Returns a collection of all requested objects found in the fanout of the specified pin, net, or port object.
get_fault_type	Returns the current fault model type, as previously specified by the <code>set_fault_type</code> command.
get_gate_pins	Returns a collection of <code>gate_pin</code> objects found below the current design in the flat model.
get_icl_extraction_options	Provides access to the settings specified by the <code>set_icl_extraction_options</code> command.
get_icl_fanins	Returns a collection of ICL objects found in the fan-in of the specified ICL objects.
get_icl_fanins_in_module	Returns a collection of objects found in the fan-in of the specified <code>icl_pin_in_module</code> or <code>icl_port</code> objects.
get_icl_fanouts	Returns a collection of ICL objects found in the fanout of the specified ICL objects.
get_icl_fanouts_in_module	Returns a collection of objects found in the fanout of the specified <code>icl_pin_in_module</code> or <code>icl_port</code> objects.
get_icl_instances	Returns a collection of all ICL instances instantiated relative to the current design that match the specified <code><*name_patterns></code> list or <code>-filter</code> expression.

Table 4-2. Commands E Through Q (cont.)

Command	Description
get_icl_modules	Returns a collection of all ICL modules that match the specified name_patterns list or -filter expression.
get_icl_module_parameter_list	Returns the list of parameters in an ICL module.
get_icl_module_parameter_value	Returns the value of the parameter on the specified module and indicates whether it is the default value or is overridden.
get_icl_network	Context: patterns -silicon_insight -ijtag
get_icl_objects	Returns a collection of ICL object matching the requested criteria.
get_icl_pins	Returns a collection of all hierarchical ICL pins instantiated relative to the current design that match the specified name_patterns list or -filter expression.
get_icl_ports	Returns a collection of all ICL ports that match the specified name_patterns list or -filter expression.
get_icl_scan_interface_chain_list	Returns the names of the explicitly defined scan chains for the specified client scan interface in an existing ICL top module, or the names of the explicitly defined scan chains for the specified client scan interface that are created in the new ICL top module during ICL extraction.
get_icl_scan_interface_list	Returns the names of the scan interfaces in an existing ICL top module, if the ICL top module exists.
get_icl_scan_interface_port_list	Returns the names of the ports for the specified scan interface in an existing ICL top module, or the names of the ports for the specified scan interface that are created in the new ICL top module during ICL extraction.
get_icl_scan_mux	Context: patterns -silicon_insight -ijtag
get_icl_scope	Introspects the current ICL scope.
get_icl_ssn_datapath_list	Returns the SSN datapath specifications added with the add_icl_ssn_datapaths, or returns the list of SSN datapaths in the ICL module of the current design.
get_icl_ssn_datapath_ports	Returns the SSN datapath specifications specified with the set_icl_ssn_datapath_ports command, or returns the collection of the SSN datapaths ports of a particular type in the ICL module of the current design.
get_iclock_list	Returns a list of ICL port and pin names on which you have issued an iClock command.

Table 4-2. Commands E Through Q (cont.)

Command	Description
get_iclock_option	Returns the effective or specified source, source type, frequency multiplier, frequency divider, clock period and other information related to the iClock or iClockOverride commands for the specified icl_port or pin_name.
get_ijtag_instances	Returns a collection of instances for which there is a matched ICL module.
get_ijtag_instance_option	Returns the value of the selected option for the specified Ijtag instance.
get_ijtag_retargeting_options	Returns the value of the specified option of the previous set_ijtag_retargeting_options command or its default value if the set_ijtag_retargeting_options command was not run.
get_input_constraints	Returns the present constraint status of primary input ports or pseudo ports.
get_insertion_option	Returns the value of any insertion option that is specifiable with the set_insertion_options command.
get_insert_test_logic_option	Retrieves a prefix/infix value that is used when logic is created by the insert_test_logic command.
get_instance_polygons	Context: patterns -scan_diagnosis
get_instances	Returns a collection of all instances instantiated relative to the current design that match the specified <i>name_patterns</i> list, subject to filtering imposed by the specified options.
get_instrument_dictionary	Returns the Tcl dictionary created by the instrument processed by process_dft_specification or process_patterns_specification.
get_instrument_parent_icl_module_list	Returns the parent or grandparent module names for ICL instance module names that match the specified <i>instrument_module_name</i> .
get_iproc_argument_default	Returns the default value for the specified arg_name of the specified proc_name attached to the ICL module specified by the last iProcsForModule command, or to the ICL module specified by module_name.
get_iproc_argument_list	Returns the list of argument names for the specified iProc attached to the ICL module that was specified by the last iProcsForModule command, or to the ICL module specified by module_name.
get_iproc_body	Returns the body for the specified iProc attached to the ICL module that was specified by the last iProcsForModule command, or to the ICL module specified by module_name.

Table 4-2. Commands E Through Q (cont.)

Command	Description
<code>get_iproc_list</code>	Returns a Tcl list of iProcs attached to the ICL module specified by the last <code>iProcsForModule</code> command, or to the ICL module specified by <code>module_name</code> .
<code>get_layout_core_instance</code>	Returns the current layout core instance that was set with the <code>set_layout_core_instance</code> command.
<code>get_license_queue_timeout</code>	Returns the value specified by the previous <code>set_license_queue_timeout</code> command.
<code>get_load_unload_timing_option</code>	Returns the value for load/unload timing options set with the <code>set_load_unload_timing_options</code> command for an <code>icl_module</code> , a module, the <code>current_design</code> , or the current physical block.
<code>get_loadboard_loopback_option</code>	Returns the settings of options specified with the <code>add_loadboard_loopback_pairs</code> command.
<code>get_logfile</code>	Returns the name of and pathway to the current log file.
<code>get_logical_library_list</code>	Returns a Tcl list with all logical design library names defined with the <code>set_logical_design_libraries</code> command.
<code>get_master_module_name</code>	Returns a string with the <code>master_name</code> attribute value for a design or icl module.
<code>get_memory_instances</code>	Returns a collection of the instances for which there is a matched TCD Memory description.
<code>get_memory_instance_option</code>	Returns the value of an option on a specific memory instance, or returns the value of an option that applies to all memory instances.
<code>get_module_matching_options</code>	Returns the settings specified with the <code>set_module_matching_options</code> and the “ <code>set_insertion_options -edited_module_prefix</code> ” commands for module matching.
<code>get_module_parameter_list</code>	Returns the list of parameters in a module.
<code>get_module_parameter_value</code>	Returns the value of the parameter on the specified module object.
<code>get_modules</code>	Returns a collection of all modules that match the specified <i>name_patterns</i> list.
<code>get_multiprocessing_option</code>	Returns the value of a single specified variable previously set with the <code>set_multiprocessing_options</code> command.
<code>get_name_list</code>	Returns the names of the specified objects, or the names of the name list with simplified escaped identifiers, if possible.

Table 4-2. Commands E Through Q (cont.)

Command	Description
get_nets	Returns a collection of all hierarchical nets instantiated relative to the current design that match the specified name_patterns list, subject to filtering imposed by the specified options.
get_open_pattern_set	Returns the name of the currently open pattern set.
get_pattern_cycle_count	Reports the total number of cycles in the currently loaded WGL or STIL test pattern set.
get_pattern_set_data	Returns requested details of the internal representation of the specified pattern set.
get_pattern_set_list	Returns a Tcl list of all existing and closed pattern sets in the order of their creation.
get_pattern_set_option	Returns the value of the requested option for the specified pattern_set_name.
get_pin_name_list	Returns the names of the associated design pins for a given collection of ICL pins.
get_pins	Returns a collection of all hierarchical pins instantiated relative to the current design that match the specified name_patterns list, subject to filtering by other options.
get_port_name_list	Returns the names of the associated design ports for a collection of ICL ports.
get_ports	Returns a collection of all hierarchical ports on the current design or a given module that match the specified filters.
get_profile_name	Returns the name of the profile that was defined using the set_profile_name command.
get_read_verilog_option	Returns the options specified with the set_read_verilog_options command.
get_resource	Returns true when all resources in the specified resource_list are available.
get_run_synthesis_options	Returns the values for options that can be set for the run_synthesis command.
get_scan_chain_families	Gets scan chain families with certain characteristics.
get_scan_chain_option	Returns the setting of an option specified in the set_scan_chain_options command.
get_scan_elements	Returns a collection of scan elements that the tool has identified in the design.
get_scan_modes	Returns the scan modes with certain characteristics.

Table 4-2. Commands E Through Q (cont.)

Command	Description
<code>get_scratch_directory</code>	Returns the absolute path to the <i>scratch</i> directory.
<code>get_silicon_insight_job_status</code>	Returns the status of diagnosis jobs that are running in the background.
<code>get_silicon_insight_option</code>	Returns current settings of options specified in the <code>set_silicon_insight_option</code> command.
<code>get_simdut_data</code>	Context: <code>patterns -silicon_insight</code> , <code>patterns -ijtag -silicon_insight</code> , <code>patterns -scan -silicon_insight</code>
<code>get_simulation_context_list</code>	Returns the available simulation contexts in a Tcl list.
<code>get_simulation_library_sources</code>	Returns the pathnames or file extensions previously specified with the <code>set_simulation_library_sources</code> command.
<code>get_simulation_option</code>	Returns the values for options that can be set for the <code>set_simulation_options</code> command.
<code>get_simulation_value_list</code>	Returns a Tcl list of the simulation values on the specified <code>gate_pin</code> objects.
<code>get_single_attribute_value</code>	Retrieves the value of an attribute on the specified design object.
<code>get_single_name</code>	Returns a string with the name of the element specified by the <i>object_spec</i> or the <i>name</i> arguments with simplified escaped identifiers, if possible.
<code>get_ssn_option</code>	Returns the status of SSN in the current physical block or design specified with the <code>set_ssn_options</code> command.
<code>get_static_dft_signal_icall</code>	Returns the iCall corresponding to the setting specified with the <code>set_static_dft_signal_values</code> command.
<code>get_synchronous_clock_groups</code>	Returns a Tcl list of collection handles. Each collection is a synchronous group of clock objects.
<code>get_system_mode</code>	Returns the system mode.
<code>get_tcl_shell_option</code>	Introspects the Tcl shell options as specified with the <code>set_tcl_shell_options</code> command.
<code>get_test_end_icall_list</code>	Returns the iCalls added to the <code>test_end</code> procedure by the <code>set_test_end_icall</code> command. Each iCall is a list containing the iProc and its arguments.
<code>get_test_point_analysis_options</code>	Returns the current setting of an option specified with the <code>set_test_point_analysis_options</code> command. If you have not specified the option, the tool returns the default value of that option.

Table 4-2. Commands E Through Q (cont.)

Command	Description
get_test_point_insertion_options	Returns the current setting of an option specified with the <code>set_test_point_insertion_options</code> command. If you have not specified the option, the tool returns the default value of that option.
get_test_point_type	Reports the current test point type as specified by the <code>set_test_point_types</code> command.
get_test_points	Returns a collection of all test points, or a collection of test points matching an optional Tcl list of specified test point attributes.
get_test_setup_icall_list	Returns the iCalls added to the <code>test_setup</code> procedure by the <code>set_test_setup_icall</code> command. Each iCall is a list containing the iProc and its arguments.
get_testbench_simulation_options	Returns the value of a given option that may have been configured using the <code>set_testbench_simulation_options</code> command.
get_timeplate_list	Returns a list of the currently defined timeplates.
get_tool_info	Returns information about the current tool and the current run as a Tcl result.
get_tool_option	Returns certain Tessent Shell options from the <code>set_tool_options</code> command.
get_trace_flat_model_option	Introspects the default behavior of the <code>trace_flat_model</code> command.
get_transcript_style	Returns the keyword that specifies the style in which the tool transcribes commands.
get_tsdb_info	An introspection command used to extract information stored in the <code>.tsdb_info</code> files found in the <code>dft_inserted_design</code> directories of the TSDB directories.
get_tsdb_list	Returns a Tcl list of directory paths, relative to the current working directory, corresponding to all opened TSDB directories.
get_tsdb_output_directory	Returns the directory used by the <code>process_dft_specification</code> command—the directory previously set by the <code>set_tsdb_output_directory</code> command.
get_validated_objects	Validates the values supplied to arguments or switches of a command created with the <code>register_tcl_command</code> command.
get_write_patterns_options	Returns introspection results from either port lists or vector callbacks.

Table 4-2. Commands E Through Q (cont.)

Command	Description
get_xclock_handling	Returns the options specified with the <code>set_xclock_handling</code> command.
get_xy_instance	Context: <code>patterns -scan_diagnosis</code> , <code>patterns -silicon_insight</code>
help	Lists commands and associated usage syntax.
history	Displays a list of previously run commands.
iApply	Triggers the retargeting of all queued <code>iRead</code> and <code>iWrite</code> commands.
iCall	Calls an <code>iProc</code> registered against the ICL module associated with the specified <i>effective_icl_instance_path</i> .
iClock	Checks whether a controlling clock path from a valid clock source to the specified clock port exists.
iClockOverride	Models how the functional clocking has been programmed.
iComparePort	Enables you to compare a value on an arbitrary primary output port or bidirectional port inside an <code>ijtag</code> pattern set.
identify_redundant_faults	Identifies redundant faults among current faults whose redundancy has not yet been determined.
iForcePort	Enables you to force a constant value to an arbitrary primary input port or bidirectional port inside an <code>ijtag</code> pattern set.
iMerge	Specifies the beginning and the end of a set of <code>iCall</code> commands that are meant to be processed in parallel, as much as possible, in the final representation of the test patterns.
import_clocks	Imports functional clocks defined during the pre-DFT design rule checking.
import_dfm	Imports a Calibre-compatible results database (RDB) file into a violations database (VDB).
import_patterns_from_svf	Enables you to integrate the actions described in the SVF file into the currently open pattern set.
import_scan_mode	Imports configuration settings from <code>tcd_scan</code> .
index_collection	Extracts a single object at a specified index in a collection and creates a new collection containing only that object.
iNote	Inserts a note in the opened pattern set.
insert_test_logic	Inserts the test structures you define into the netlist and stitches up the scan chains to increase the design's testability.

Table 4-2. Commands E Through Q (cont.)

Command	Description
intercept_connection	A command that uses the <code>get_dft_cell</code> command to obtain a cell with the specified function name and uses it to intercept a connection to a pin, port, or net.
iOverrideScanInterface	Imposes user-specified behavior on the operation of a <code>ScanInterface</code> .
iPDLLevel	Identifies the level and version of PDL commands.
iPrefix	Sets the <code>iPrefix</code> path that is used to compute the <code>effective_icl_instance_path</code> for the <code>iCall</code> command and other PDL commands.
iProc	Specifies a PDL procedure that can run later when referenced by the <code>iCall</code> command.
iProcsForModule	Specifies the ICL module for which subsequent <code>iProc</code> commands refer to.
iPulseClock	Starts or restarts a synchronous clock that previously has been forced to its off-state by means of the <code>iForcePort</code> command.
iRead	Adds a read operation to the command queue to be solved by the next <code>iApply</code> command.
iRelease	Releases a resource previously taken by means of <code>iTake</code> .
iReset	Adds a sequence of actions to the current pattern set that is required to set the ICL network into the reset state.
iRunLoop	Creates a vector loop of a given duration.
is_collection	Indicates whether string is a collection handle.
isolate_icl_node	Context: <code>patterns -silicon_insight -ijtag</code>
iTake	Takes ownership of ICL resources to prevent the retargeting software from altering their states during the processing of subsequent <code>iApply</code> commands or during the processing of concurrent <code>iProcs</code> in <code>iMerge</code> parallelization.
iTopProc	Specifies a PDL procedure that can run later when referenced by the <code>iCall</code> command, when its associated ICL module is the top level module.
iUseProcNameSpace	Specifies a name space that is used for all subsequent <code>iCalls</code> made within the <code>iProc</code> in which the <code>iUseProcNameSpace</code> command appears.
iWrite	Adds a write operation to the command queue to be solved by the next <code>iApply</code> command.

Table 4-2. Commands E Through Q (cont.)

Command	Description
launch_sid_tester	Directs Tessent Shell to launch the SID tester process on a local host using the selected <code>_tester</code> and the port number as specified in the configuration data file.
lock_current_registration	Locks all previously registered commands and attributes preventing them from being unregistered and modified.
macrotest	Generates manufacturing test patterns for embedded logic and memories referred to as macros.
merge_cdp	Merges legacy LV flow and Tessent-Shell-based ESOE CDPs into the current Tessent Shell-based CDP.
migrate_layout	Generates an LDB directory hierarchy that contains the specified preexisting LDB.
move_config_element	Moves a configuration element from one location to another.
move_connections	Moves connections from pin or net objects to pin objects.
no_transcript	Turns off transcribing for the specified commands.
open_layout	Opens an existing Tessent Diagnosis tool-compatible Layout Database directory.
open_pattern_set	Opens an empty named pattern set and makes it ready to be populated with the specified PDL commands.
open_tsdb	Makes the contents of the TSDB directory visible to the tool. The specified TSDB output directory is automatically opened.
open_visualizer	Opens the Tessent Visualizer window.
order_patterns	Reorders the internal test pattern set as specified.
printenv	Prints out the values of the Linux environment variables.
process_atpg_failures	Interprets ATPG failure log files generated on ATE and produces flop failure files for a given characterization and debug package (CDP) and test.
process_dft_specification	Validates and processes the content contained in a <code>DftSpecification</code> wrapper.
process_patterns_specification	Validates and processes the content of the <code>PatternsSpecification</code> (<i>design_name</i> , <i>design_id</i> , <i>pattern_id</i>) wrapper.

echo

Context: unspecified, all contexts

Mode: all modes

Issues a user-defined string to the transcript.

Usage

```
echo "string" [{> | >>} file_pathname]
```

Description

Issues a user-defined string to the transcript.

The echo command issues a user-defined string to the transcript or to a pathname, if you use one of the file redirection operators.

Note

 Commands that use either the > or >> file redirection operator are first checked for correctness. Syntax errors are reported to the display prior to the command's execution. The redirection operator does not hide these errors.

Arguments

- *string*
A required string. The string that you want echoed to the transcript. Double quotation marks are required if the string contains spaces or special characters.
- > *file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- >> *file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example redirects output from several commands into a single output file, *my_scan_report*. The first command creates or replaces the *my_scan_report* file. The second and following commands append to the same file.

```
echo "----- scan cells -----" > my_scan_report
report_scan_cells >> my_scan_report
echo "----- scan chains -----" >> my_scan_report
report_scan_chains >> my_scan_report
```

[set_transcript_style](#)

elaborate_icl_modules

Context: all contexts

Mode: all modes

Prerequisites: There must be ICL for the specified modules and for all of their descendants.

Elaborates the specified ICL modules.

Usage

`elaborate_icl_modules obj_spec`

Description

For certain ICL tracing commands, like [get_icl_fanins_in_module](#) or [get_icl_fanouts_in_module](#), and for the introspection of objects of certain types, like [icl_pin_in_module](#), it is required to have elaborated ICL modules. Usually, the ICL elaboration happens when the current design is set or after ICL extraction has finished, but it can be triggered explicitly by means of the command `elaborate_icl_modules`. The ICL elaboration resolves parameters and expressions, creates internal representations of individual bits of ports and registers, remodels complex ICL building blocks (for example, `OneHotDataGroup`) and creates explicit connections for elements that are only implicitly connected. In order to resolve instance port bindings and hierarchical aliases, the command invokes the elaboration of the specified modules and of all of their descendants. Therefore, the ICL for all of those modules must have been read earlier by means of the [read_icl](#) command.

Arguments

- *obj_spec*

A required value that specifies a list of one or more ICL module names or a collection of one or more `icl_module` objects.

Examples

```
elaborate_icl_module {tap block1 block2}
```

encrypt_layout

Context: patterns -scan_diagnosis

Mode: setup

Encrypts a layout database (LDB) for purposes of data transfer.

Usage

encrypt_layout *ldb_path* [-replace]

Description

Note

 The encryption process is destructive in nature because once the names are removed, they cannot be returned to the LDB. Keep a golden original copy of the LDB for archival purposes.

This command is useful for transferring design and layout data to third parties (such as to foundries). The command removes net and instance names from the LDB and encrypts the remaining design and all of the layout data within the LDB name you specify. The only use should be for layout-aware diagnosis in the Tessent environment.

After encryption, Tessent YieldInsight flows and other flows that rely on layout names do not work. This is to be expected and is the recommended state for security. Other affected flows include (but are not limited to) those using commands that act on real design names (such as report_instance_polygon), commands that manipulate layout core information (such as add_layout_core_information), and the open_layout -verify command.

Layout-aware and chain diagnosis, and RCD/RCAD constant creation, function as normal. Within the LDB, layer and via names remain un-encrypted to enable design (for example, GDS-based) debugging and the RCD flow.

Note

 Encryption based on compressed layout data is not supported. Before encrypting the LDB, uncompress the layout data by using the uncompress_layout command.

Arguments

- **ldb_path**
A required string that specifies the pathname of the encrypted LDB. An error occurs if you attempt to name the encrypted LDB the same name as the source LDB.
- **-replace**
An option that specifies to overwrite an existing encrypted LDB of the same name.

Examples

The following example opens an existing LDB and encrypts it under a new name.

```
open_layout ../design.layout  
encrypt_layout ../design_encrypted
```

execute_cdp_test

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Runs the specified test using the currently connected tester.

Usage

```
execute_cdp_test test_name [-collect_data_type_list data_type_list]  
[-force_diagnose_on_failure]
```

Description

By default, this command returns pass/fail (go-nogo) results for the associated test procedure. When you specify `-collect_data_type_list` option, the tool collects the failure data during test execution and returns the data in a tabulated format. The tool provides the failing data with respect to the ReadVar variables originally specified in the PDL that you used to generate the pattern.

This command returns a “0” if the test passes, and a “1” if it fails, which enables you to create scripts leveraging the status.

When you are using SimDUT as your tester, the tool converts the test pattern file to simulation events, and then the Verilog simulator returns the failing information to SimDUT.

Arguments

- ***test_name***
A required string that specifies the name of the test you want to run.
- **`-collect_data_type_list` *data_type_list***
An optional switch and literal that specifies the type of failure data to return. The data type options are:
 - gonogo—pass/fail results
 - raw_fails—the number failures only; returns 0 if the test passed.
 - variable—failing variables/registers
 - instrument—failing instruments
 - diagnosis—diagnosis datalog for failing instruments
- **`-force_diagnose_on_failure`**
An optional switch that forces automatic failure diagnosis if the specified test fails.

Examples

Example 1

The following example runs test1 on the DUT and returns the results for the collect_failures procedure for the test pattern associated with test1.

execute_cdp_test test1 -collect_data_type_list variable

```
// command: execute_cdp_test test1 -collect_data_type_list variable
// Test 'test1' failed.
// Variable failures and unmapped failures of pattern
// 'DLV2_1S0_ETMemory_Full.svf' :
//
// PatternSet  Variable                                Pin  Expected
//                                     -----  -----
//                                     -----  -----
//          main          BP2_WIR.IR_STATUS2      TDO          b1
//                                     -----  -----
//                                     -----  -----
//          main          BP2_WIR.IR_STATUS1.DONE  TDO          b1
//                                     -----  -----
//                                     -----  -----
//          main          BP2_WDR.WBP1_INST_POINTER_REG  TDO          b000000
//                                     -----  -----
//                                     -----  -----
//          main          BP2_WDR.WBP1_A_ADD_REG_Y    TDO          b0000
//                                     -----  -----
//                                     -----  -----
//          main          BP2_WDR.WBP1_A_ADD_REG_X    TDO          b0000
//                                     -----  -----
//                                     -----  -----
//          main          BP2_WDR.WBP1_GO_ID_REG10  TDO          b0
//                                     -----  -----
//                                     -----  -----
```

Example 2

The following example runs MemoryBist_P1 on the DUT and returns the results for the collect_failures procedure for the test pattern associated with MemoryBist_P1.

execute_cdp_test MemoryBist_P1 -collect_data_type_list {variable diagnosis}

execute_cdp_test

```
// command: execute_cdp_test test1 -collect_data_type_list {variable diagnosis}
// Test 'MemoryBist_P1' failed.
// Variable failures and unmapped failures of pattern 'MemoryBist_P1.stil' :
//
// PatternSet      Variable                                                    Pin Expected
//                                                         Actual
// -----

```

Example 3

The following command returns the pass/fail results for the test pattern associated with test2.

```
execute_cdp_test test2
```

```
command: execute_cdp_test test2
Test 'test2' failed.
```

Example 4

The following script runs the MemoryBist_P1 test ten times, captures the pass/fail results, and reports the results.

```
# Run test 10 times and capture pass/fail results
set status_array {}
for { set i 1 } { $i <= 10 } { incr i } {
    lappend status_array [ execute_cdp_test MemoryBist_P1 ]
}
# Report results after all tests complete
set i 1
foreach failflag $status_array {
    puts -nonewline "** Test $i : "
    if { $failflag } { puts "FAIL" } else { puts "PASS" }
    incr i
}
** Test 1 : PASS
** Test 2 : PASS
** Test 3 : PASS
** Test 4 : PASS
** Test 5 : FAIL
** Test 6 : PASS
** Test 7 : PASS
** Test 8 : PASS
** Test 9 : PASS
** Test 10 : PASS
SETUP>

[add_cdp_test](#)

[launch_sid_tester](#)

execute_gpib_command

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Enables you to control and program GPIB equipment.

Usage

```
execute_gpib_command gpib_command -address gpib_address [-read_result [-timeout  
read_timeout_period]]
```

Description

Note

 Using this command assumes that you have configured the equipment on the GPIB as described in General Purpose Interface Bus (GPIB) standard IEEE-488. It also assumes that the GPIB instrument supports the GPIB commands you specify.

In Tessent SiliconInsight, you generally use GPIB equipment to control power supplies and clock generators for testing purposes. However, you may also control any GPIB instrument—such as a PMU, temperature control, or digital IO—as long as it supports the GPIB standard.

To control GPIB instruments with Tessent SiliconInsight, use the [Prologix 6.0 adaptor](#). Connect this adaptor to a USB port on the Desktop computer and route the GPIB cables from the adaptor to the GPIB instruments. You do not need a setup file. Refer to “[Setting Up the Desktop Environment](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell* for details.

Combining this command with the `execute_cdp_test` and `add_cdp_test` commands enables you to generate detailed programs for debugging and characterizing DUTs.

Arguments

- **gpib_command**
A required string that specifies a GPIB command and arguments. The GPIB command must be a valid GPIB command that is supported by the targeted GPIB instrument. Specify the command between quotation marks.
- **-address gpib_address**
A required switch and integer pair that specifies the address of the targeted GPIB equipment, where the **gpib_address** is an integer from 0 to 30. This switch enables execution of the GPIB command on the GPIB equipment configured to listen at the specified address.
- **-read_result**
An optional switch that directs Tessent SiliconInsight to read the results that the GPIB equipment returns after it runs the specified GPIB command. Use this switch when the

GPIB command is a query command and you expect a query result from the GPIB equipment. By default, the tool does not read data from the GPIB instrument.

- `-timeout read_timeout_period`

An optional switch and integer pair that specifies the maximum length of time (in milliseconds) to wait for the result of the specified command to appear on the GPIB before timing out. The default wait period is 2 seconds (2000 ms).

Examples

Refer to “[Examples of Controlling Instruments With GPIB](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell* for more examples.

Example 1

The following shmo script sweeps the power from 1.1V to 2.5V with increments of 0.1V, and clock frequency from 500MHZ to 1000MHZ with increments of 100MHZ. It shows that the GPIB command for the clock frequency is “SetFrequency *frequency*” and for the power supply is “SetVoltage *volts*”.

The assumptions are:

- The Prologix USB-to-GPIB adaptor is physically connected to the Desktop computer.
- The Prologix adaptor cables connect to a clock generator at GPIB address 5 and a power supply (PS) at GPIB address 8, and the GPIB instruments are correctly configured per their documentation.
- The MemoryBist_P1 test was loaded into the hardware using the `add_cdp_test` command.

execute_gpib_command

```

# As a best practice, before running the script, verify responsiveness
# of the instruments on the GPIB network. The following commands
# return strings that identify the instruments.

execute_gpib_command "*IDN?" -address 5 -read_result
execute_gpib_command "*IDN?" -address 8 -read_result

# The shmoo script
for { set p 1.1 } { $p <= 2.5 } { incr p 0.1 } {
  # Set the voltage
  execute_gpib_command { SetVoltage $p } -address 8
  for { set frq 500 } { $frq <= 1000 } { incr frq 100 } {
    # Set the frequency for the clock generator
    execute_gpib_command { SetFrequency $p } -address 5

    # Run the test
    set test_failed [execute_cdp_test MemoryBist_P1]
    puts -nonewline "PS=${p}V FRQ=${frq}MHZ test="
    if { $test_failed } {
      puts "Failed"
    } else {
      puts "Passed"
    }
  }
}

```

Example 2

The following command directs the tool to run the ReadCurrent command on the GPIB instrument that is enabled at address 12. The ReadCurrent command returns results, which Tessent SiliconInsight Desktop then reads because you have specified the -read_result switch. The tool waits no more than 500 ms for the results to appear.

```
execute_gpib_command "ReadCurrent" -address 12 -read_result -timeout 500
```

Related Topics

[add_cdp_test](#)

[execute_cdp_test](#)

execute_tester_command

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Enables you to verify and debug the wiring connection between an adaptor used for Tessent SiliconInsight and the design under test.

Usage

```
execute_tester_command [exec_vecs adaptor_pin_list vector_list]
    [find_ir_length [trst tms tdi tdo tck]]
    [check_intermittent_failures pattern_filename maximum_iterations]
```

Description

Enables you to verify and debug the wiring connection between an adaptor used for Tessent SiliconInsight and the design under test.

Use the `exec_vecs` option to program any of the supported Tessent SiliconInsight adaptors' pins to logic values 0 and 1. Doing this can help you debug the wiring between the adaptor and the DUT.

Use the `find_ir_length` option to verify that the TAP controller, if present, is wired correctly. If the command returns an error instead of the length of the instruction register, then the TAP pins are not wired correctly.

Refer to “[Debug the Wiring Connection Between the Adaptor and the DUT](#)” in the *Tessent SiliconInsight User's Manual for Tessent Shell* for details.

Arguments

- `exec_vecs`
An optional literal string that specifies to run the specified vectors at the specified logic values.
- `adaptor_pin_list`
A list that specifies one or more pin names on the adaptor that you want to control.
- `vector_list`
A list of logic values (0 or 1) for the specified pins.
- `find_ir_length`
An optional literal string that specifies to verify that the five adaptor pins that connect to TAP controller pins are wired correctly. When specified without TAP pin assignments, the tool defaults to using the TAP pin mapping defined in the adaptor's setup specification Pinmap wrapper.

- *trst tms tdi tdo tck*

An optional ordered list of pin numbers that corresponds to the five pins that connect the adaptor to the TAP controller. Specify the pin numbers in the order indicated by the command syntax.

- *check_intermittent_failures*

An optional literal string that activates the check for intermittent failures for a given pattern. If an intermittent failure is detected, the tool generates a message similar to the following in *sid_tester.log*:

```
Check for intermittent fails; iteration = 1
Check for intermittent fails; iteration = 2
WARNING: INTERMITTENT_FAILURE: Got intermittent fails for
'MemoryBist_P1_2.svf' on iteration 2.
  Previous run failures: ' 13@5@3 17@25@3 17@34@3 17@56@3 17@63@3 '
  Current run failures: ' 13@5@3 17@25@3 17@34@3 17@56@3 17@63@3 17@63@8 '
```

Search the log file for “INTERMITTENT_FAILURE” to locate all instances of intermittent failures.

- *pattern_filename*

An optional filename that specifies the diagnostic pattern to use to check for intermittent failures.

- *maximum_iterations*

An optional integer that specifies the maximum number of iterations to run when checking for intermittent failures.

Examples

Example 1

The following example for a signalizerSHA40 adaptor sets pins C0 and C7 to 1 and the rest of the pins (C1, C2, C3, C4, C5, and C6) to 0:

```
execute_tester_command exec_vecs { C0 C1 C1 C3 C4 C5 C6 C7 } 1000001
```

Example 2

The following example runs the diagnostic pattern in *MemoryBist_P1_2.svf* up to 250 times to check for intermittent failures when running the test *MemoryBist_P1*:

```
execute_tester_command check_intermittent_failures MemoryBist_P1_2.svf 250
```

exit

Context: unspecified, all contexts

Mode: all modes

Terminates the application tool program.

Usage

exit [-force] [*exitval*]

Description

Terminates the application tool program.

The exit command terminates the tool session and returns to the operating system. You should either save the current test patterns or modified design before exiting the tool.

If you are operating in interactive mode (not running a dofile) and you do not save the current test pattern set or modified design, the tool displays a warning message, and you are given the opportunity to continue the session and save the test patterns before exiting.

Arguments

- -force

An optional argument that forces termination of the current tool session without saving any data.

- *exitval*

An optional integer that specifies an exit code.

This option can be used to return a non-zero value when exiting the tool. By default, when there's no error, "0" is returned to the caller while non-zero usually indicates an error condition. The specific value returned can be used to differentiate the type of condition that resulted in issuing the exit command. When a tool terminates on a fatal signal whose number is *N*, the tool uses the value 128+*N* as the exit status.

Examples

The following example quits the tool without saving the current test pattern set.

```
set_system_mode analysis
create_patterns
exit -force
```

expand_compressed_patterns

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Expands compressed 1-hot patterns for better internal failing flop diagnosis.

Usage

```
expand_compressed_patterns [-CHAIN chain_name...]  
    [-MAX_1hot_pattern pattern_number] [-MAP_file map_filename] [-REPlace]
```

Description

Expands compressed 1-hot patterns for better internal failing flop diagnosis.

See “[1hot Compressed Pattern Expansion](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

Arguments

- **-CHAIN *chain_name*...**
An optional switch and repeatable string that identifies the scan chain name(s) to process for 1-hot expansion.
- **-MAX_1hot_pattern *pattern_number***
An optional switch and required integer that specifies the maximum number of patterns to produce during expansion. The default value is 1000. If this limit is exceeded, the tool stops command execution and prints a warning message that the limit was exceeded.
- **-MAP_file *map_filename***
An optional switch and required string that specifies the map filename where 1-hot pattern-IDs, original pattern-IDs, and mapped channel information is saved. Use the -replace option to overwrite an existing map file.
- **-REPlace**
An optional switch for overwriting an existing file.

extract_fault_sites

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Prerequisites: The design must be flattened to the simulation model, and you must have a Layout Database opened using the [open_layout](#) command.

Extracts interconnect bridges and opens from a layout database and writes out the data in UDFM file format.

Usage

```
extract_fault_sites -output_file output_filename  
  [-defect_types {all | bridges | opens}]  
  [-min_tca min_tca_value]  
  [-max_tca max_tca_value ]  
  [-max_distance max_distance_value]  
  [-max_defects {max_defects_value | unlimited}]  
  [-max_bridges {max_bridges_value | unlimited}]  
  [-max_opens {max_opens_value | unlimited}]  
  [-open_sorting {segment | net}]  
  [-critical_area_calculation {method1 | method2}]  
  [-strip_prefix prefix]  
  [-add_prefix prefix]  
  [-marker_file filename]  
  [-replace]  
  [-verbose]  
  [-details {on | off}]
```

Description

This command extracts interconnect bridges and opens from a [Layout Database](#) (LDB) and writes them to a file in UDFM file format.

Note

 The extract_fault_sites command is only compatible with LDBs created with Tessent v2014.4 or later.

For complete information, refer to “[Interconnect Bridge and Open Extraction and UDFM Creation](#)” in the *Tessent Scan and ATPG User’s Manual*.

Note

 Using this command requires an Automotive-Grade ATPG license feature. See “[Feature Entry in the License File](#)” in the *Managing Tessent Software* manual.

When running the `extract_fault_sites` command, the tool outputs a summary of the applied fault site extraction settings and a distribution graph, displaying the number of defects in relation to the total critical area. Refer to “[Example 6](#)” on page 810 for an example.

Arguments

- `-output_file output_filename`

A switch and string pair that specifies the name of the UDFM file into which the tool writes the extracted fault sites. The UDFM files are automatically compressed if the extension is `.gz`.

- `-defect_types all | bridges | opens`

An optional switch and literal pair that specifies the defect type(s) the tool writes to the UDFM file.

`all` — Writes out both bridges and opens.

`bridges` — Writes out all bridges including those to power and to ground. This is the default.

`opens` — Writes out opens.

You specify multiple defect types using the following syntax:

```
-defect_types {bridges opens}
```

- `-min_tca min_tca_value`

An optional switch and value pair that specifies the minimum total critical area of a defect to be extracted from the LDB. A valid *min_tca_value* is a non-negative real number. The tool extracts all defects with a total critical area greater than or equal to the specified value. The default is 0, which means no limitation is set.

- `-max_tca max_tca_value`

An optional switch value pair that specifies the maximum total critical area of a defect to be extracted from the LDB. A valid *max_tca_value* is a non-negative real number. By default no limitation is set.

- `-max_distance max_distance_value`

An optional switch and value pair that specifies the maximum distance between two nets to be accepted as a bridge defect. A valid *max_distance_value* is a non-negative real number, where the specified number is the factor to be multiplied by the technology length to calculate the real physical distance.

The default is 3.0; this means that by default the tool only extracts from the LDB those bridges with a distance between the nets of three times the technology length, or less.

This setting has no effect on interconnect open defects.

- `-max_defects max_defects_value | unlimited`

An optional switch and value or literal pair that specifies the maximum total number of defects (containing bridges and opens) the tool writes to the UDFM file. Specify one of the following:

max_defects_value — A natural number that specifies the maximum number of defects.

`unlimited` — A literal that instructs the tool to write all defects to the UDFM file. This may cause increases in both runtime and the size of the output file. This is the default.

- `-max_bridges max_bridges_value | unlimited`

An optional switch and value or literal pair that specifies the maximum number of bridges the tool extracts from the LDB. Specify one of the following:

max_bridges_value — A natural number that specifies the maximum number of bridges.

`unlimited` — A literal that instructs the tool to extract all bridges from the LDB. This may cause increases in both runtime and the size of the output file. This is the default.

- `-max_opens max_opens_value | unlimited`

An optional switch and value or literal pair that specifies the maximum number of opens the tool extracts from the LDB. Specify one of the following:

max_opens_value — A natural number that specifies the maximum number of opens.

`unlimited` — A literal that instructs the tool to extract all opens from the LDB. This may cause increases in both runtime and the size of the output file. This is the default.

- `-open_sorting segment | net`

An optional switch and literal pair that defines the sorting of the open's section in the UDFM file. Specify one of the following:

segment — A literal that instructs the tool to sort the open groups in descending order by segment, specifically by the total critical area of the corresponding net segment of the open groups. This is the default.

net — A literal that instructs the tool to sort the list of fault definitions using the following two levels:

- **First Level** — The tool sorts in descending order the fault definitions by the summarized total critical area of all segments for each open group.
- **Second Level** — The tool sorts all fault definitions for the segments of a particular open group in descending order by the specific total critical area value.

- `-critical_area_calculation method1 | method2`

An optional switch and literal pair that specifies the method the tool uses to calculate the critical area. Choose one of the following:

method1 — An integral calculation. Depending on the specified defect type, either method 1 for bridges, or method 1 for opens and vias is applied. This is the default. Refer to "[Critical Area Calculation Formula for Bridges](#)" and "[Critical Area](#)

[Calculation Formula for Opens and Vias](#)” in the *Tessent Scan and ATPG User’s Manual*.

method2 — An analytical solution based on a wider range of bridge defects but taking critical area saturation into account. Refer to “[Alternative Critical Area Calculation Formula for Bridges](#)” in the *Tessent Scan and ATPG User’s Manual*.

Note

 As method 2 is only supported for bridges, the tool issues an error message when you specify method 2 with the “-defect_types opens” switch and literal.

- **-strip_prefix *prefix***
An optional switch and string pair that removes the prefix of the net path name if there is an inconsistency between the flat model and LDB net names.
- **-add_prefix *prefix***
An optional switch and string pair that adds a prefix to the net path name if there is an inconsistency between the flat model and the LDB net names.
- **-marker_file *filename***
An optional switch and string pair that instructs the tool to generate a marker file with the specified *filename* and that contains the extracted defects.
- **-replace**
An optional switch that instructs the tool to overwrite the contents of a UDFM or marker file in the event a file of the same name exists.
- **-verbose**
An optional switch that instructs the tool to output the progress of the various steps of the `extract_fault_sites` command.
- **-details on | off**
An optional switch and literal pair that controls the amount of data extracted from the LDB. Specify one of the following:
 - on — A literal that instructs the tool to extract verbose information from the LDB. This is the default.
 - off — A literal that instructs the tool to extract only essential information from the LDB resulting in smaller UDFM output files.

Examples

Example 1

In this example, the tool extracts interconnect bridges with the command’s default parameters. As a result, the tool-generated UDFM file, *interconnect_bridges.udfm*, contains all interconnect bridges with a distance between the bridging objects up to three times the technology length. The `-max_distance` switch’s default is 3.0; consequently, the tool considers interconnect bridges up to three times the technology length.

```
set_context patterns -scan_diagnosis
read_flat_model design.flat.gz
open_layout design.ldb
// optionally, specify the set_marker_file_options marker_file_options here.
```

```
extract_fault_sites -defect_types bridges -output_file interconnect_bridges.udfm \
  -marker_file interconnect_bridges.marker
```

Example 2

In this example, the tool extracts interconnect opens.

The tool-generated UDFM file is named *interconnect_opens.udfm*, and the tool-generated marker file is named *interconnect_opens.marker*. The maximum number of opens is set to “unlimited”, which means the tool extracts all existing opens and writes the result to the UDFM file, regardless of the total critical area. For the marker file, the number of opens the tool writes to the file depends on the settings for the marker file options. See [set_marker_file_options](#).

```
extract_fault_sites -defect_types opens -output_file interconnect_opens.udfm \
  -marker_file interconnect_opens.marker -max_opens unlimited
```

Example 3

In the following example, the default defect type “bridges” is applied. The tool extracts interconnect bridges up to a defect size of 10 times the technology length. In addition, the tool only writes out those bridges with a TCA value greater than or equal to 100. The tool-generated UDFM file is named *interconnect_bridges.udfm*, and the tool-generated marker file is named *interconnect_bridges.marker*.

```
extract_fault_sites -output_file interconnect_bridges.udfm \
  -marker_file interconnect_bridges.marker -max_distance 10.0 -min_tca 100.0
```

Example 4

In this example, the tool creates three UDFM files and their corresponding marker files. By default, the tool only considers the defect type “bridges” for each file pair.

- The first `extract_fault_sites` command creates a UDFM file for the bridges with the total critical area equal or greater than 100.0.
- The second `extract_fault_sites` command creates a UDFM file for the bridges that have a total critical area in the range of a value equal or greater than 100.0 up to 1000.0.
- The third `extract_fault_sites` command creates a UDFM file for the bridges with a total critical area in the range of a value equal or greater than 100.0 up to 500.0. That means, all bridges with a total critical area less than 100 or greater than 500 are not written out.

extract_fault_sites

```
extract_fault_sites -output_file tca_100_or_greater.udfm \
  -marker_file tca_100_or_greater.marker -min_tca 100.0
```

```
extract_fault_sites -output_file tca_100_1000.udfm -marker_file tca_100_1000.marker \
  -min_tca 100.0 -max_tca 1000.0
```

```
extract_fault_sites -output_file tca_100_500.udfm -marker_file tca_100_500.marker \
  -max_tca 500.0 -min_tca 100.0
```

Example 5

In this example, the tool extracts both interconnect bridges and opens. The tool extracts interconnect bridges up to a distance of 10 times the technology length. For opens, the tool does not consider the `-max_distance` switch setting. The tool-generated UDFM file is named *all.udfm*, and the tool-generated marker file is named *all.marker*.

```
extract_fault_sites -output_file all.udfm -max_distance 10 -defect_types { all } \
  -marker_file all.marker -verbose
```

The output of the `-verbose` switch provides additional information about the progress of the various steps and looks as follows:

```
// Interconnect bridge extraction started...
// Interconnect bridge extraction completed.
// 1101486 bridges have been ignored due to distance filtering
//   (max. distance: 3.000).
// Bridge fault location mapping started...
// 10% of the bridge fault location mapping has been performed.
//   Estimated remaining effort: 304 sec
// 20% of the bridge fault location mapping has been performed.
//   Estimated remaining effort: 249 sec
// 30% of the bridge fault location mapping has been performed.
//   Estimated remaining effort: 213 sec
// 40% of the bridge fault location mapping has been performed.
//   Estimated remaining effort: 180 sec
// 50% of the bridge fault location mapping has been performed.
//   Estimated remaining effort: 148 sec
// 60% of the bridge fault location mapping has been performed.
//   Estimated remaining effort: 118 sec
// 70% of the bridge fault location mapping has been performed.
//   Estimated remaining effort: 87 sec
// Bridge fault location mapping completed.
```

Example 6

This example illustrates the log file output that contains a summary of command line options, and a distribution graph containing the number of defects in relation to the total critical area:

```
extract_fault_sites -output_file apt1_EXT_bridges_tca0_100000.udfm \
  -marker_file apt1_EXT_bridges_tca0_100000.marker -defect_type bridges \
  -max_bridges unlimited -max_distance 10.0 -min_tca 0 -max_tca 100000 \
  -strip_prefix /top -replace
```

```

//          |                                     # Bridges
//          |          10          100          1000          10000          100000          1000000
//          |          |          |          |          |          |          |

```

extract_icl

Context: all contexts

Mode: all modes

Checks the ICL connectivity rules between IJTAG instances, extracts the top-level ICL module, creates an SDC file that can be used for synthesis and static timing analysis (STA), and extracts an IJTAG graybox model.

Usage

```
extract_icl [-write_in_tsdb {on | off | auto}] [-skip_sdc_extraction]
            [-create_ijtag_graybox on | off] [-variant_icl_id variant_id]
```

Description

Refer to the [extract_sdc](#) command for details on SDC file creation and usage.

Using the `extract_icl` command is almost identical to explicitly using “`set_context patterns -ijtag`” followed by “`set_system_mode analysis`” with the following notable differences:

1. If ICL is already elaborated, using “`set_system_mode analysis`” in context “`patterns -ijtag`” does not extract a new version of the top ICL module. The tool simply transitions to analysis mode so that you can use the currently elaborated ICL to retarget PDL. When you call `extract_icl`, the top level ICL module is deleted and a new one is forced to be re-extracted.
2. If you change the module matching options using the `set_module_matching_options` command, it only has effect the next time ICL matching is done. You have to reissue the “`set_context patterns -ijtag`” command or the `set_current_design` command to redo the ICL module matching. Using the `extract_icl` command, the module matching is redone systematically.
3. If the ICL is already elaborated and there are input constraints added on the top level IJTAG ports, they are automatically deleted prior to running ICL extraction. Those constraints are automatically added in a previous step if the ICL was elaborated and a setup to analysis transition was done such that the value loaded in the ICL network did not get disturbed during the state stability check.
4. If the ICL is already elaborated when the `extract_icl` command is called and the top ICL module contains ScanInterfaces, the name of those scan interfaces and their port list is stored before the current top level ICL module is deleted so that the original names and port list can be restored in the re-extracted top level ICL module.
5. Finally, when you use `extract_icl`, the context from which it was called is restored once the ICL is extracted. The “`set_system_mode analysis`” command leaves you in the analysis mode of the “`patterns -ijtag`” context.

As documented in the “[dft_inserted_designs](#)” section of the “[Tessent Shell Data Base \(TSDB\)](#)” on page 4485, if the `-write_in_tsdb` switch is not specified to off, the PDL files associated to the

ICL files that were checked are collected into a single file and stored beside the extract ICL file. The extracted PDL file is also automatically sourced into memory after extraction. Each time the extracted ICL file is read in and the top ICL module elaborated using the `set_current_design` command, the PDL file is automatically sourced on memory.

As described in [Table 3-12](#) on page 206 of the `add_dft_signals` command reference page, the `all_test` DFT signal is treated in a special manner during ICL extraction. Because the tool has automation to make sure the `all_test` DFT signal is always high during ICL usage, Tessent Shell forces this DFT signal to high to enable sensitizing clock gaters so that the clock path can be extracted and modeled in ICL. The ICL representation does not describe the clock gater and would become invalid if the `all_test` signal was not automatically set to 1. If you are using Tessent MemoryBIST and use the pre-DFT DRC `DFT_C1`, any clock gaters seen fanning out to memories are turned off by a special DFT signal called `nonscan_test`. Again, the clock gaters are not modeled in the ICL representation but there are no issues because the memoryBIST PDL automatically sets this DFT signal to 1 during all memory BIST patterns. If you want to use a different DFT signal to enable your clock gater, you must model the clock gater in ICL, as shown in “[Example 3](#)” on page 815 below.

Flow to Avoid Re-Running `extract_icl`

You can avoid having to re-run the `extract_icl` command on a parent block after redoing DFT insertion on a child block. This is possible only when the interface of the child block did not change as a consequence of redoing DFT insertion. You can still choose to re-run the `extract_icl` command to update the ICL/PDL.

For example, suppose that DFT insertion step named “gate” on a child block “core” is redone, which does not change the footprint of the block (no port changes to the child) but changes the netlist/ICL/PDL. After this finishes, it is possible to update the parent design “top” DFT insertion pass “gate” without having to run ICL extraction by running the following commands:

```
set_context dft -design_id gate
# The following skips reading ICL/PDL for child blocks.
read_design top -design_id gate
# Read all child blocks designs make sure all ICL/PDL in memory is
# current.
open_tsdb core.tsdb
read_design core -design_id gate -view interface
set_current_design top
write_design -tsdb -replace
```

Logic Synthesis and Port Name Mapping

Logic synthesis can flatten or bit-blast ports, causing post-synthesis names to differ from those in the initial RTL. This process is automatic and typically does not require user intervention. For more information, refer to “[Automatic Design Mapping](#)” in the *Tessent Shell User’s Manual*.

Arguments

- `-write_in_tsdb on | off | auto`

An optional switch and literal pair that controls whether the extracted ICL is automatically written out in the specified TSDB output directory. The TSDB output directory is specified with the [set_tsdb_output_directory](#) command and defaults to “tsdb_outdir”.

The auto value means “on” when the directory returned by [get_tsdb_output_directory](#) already exists, otherwise auto means “off.”

With the default value of “auto”, the ICL file is only written if the directory `tsdb_outdir/dft_inserted_designs/current_design_design_id.dft_inserted_design` already exists. This directory is typically created by the [process_dft_specification](#) command prior to invoking the `extract_icl` command as shown in [Example 1](#).

- `-skip_sdc_extraction`

An optional switch that specifies skipping SDC generation during ICL extraction.

- `-create_ijtag_graybox on | off`

An optional switch and literal pair that creates an IJTAG graybox view within the TSDB output directory. This feature requires an SSN license. When you run `extract_icl` in RTL mode, you can generate the IJTAG graybox during ICL extraction because the tool automatically calls quick synthesis when there is RTL logic between the IJTAG instances. Quick synthesis internally calls the “`analyze_graybox -ijtag`” command followed by the “`write_design -graybox`” command. Refer to the [analyze_graybox](#) reference page for more information about IJTAG graybox analysis.

If you need extra instances to be preserved in the IJTAG graybox view, set the [preserve_in_graybox](#) attribute on those instances before you call the `extract_icl` command.

- `-variant_icl_id variant_id`

An optional switch and string pair that specifies an ICL variant identifier. It causes extraction of an additional ICL file to the TSDB output directory named “`design_name.icl_variant_id`.” A variant ICL file may be necessary if a design has constructs that you cannot represent in ICL. For example, a bidirectional port does not exist in ICL. It is also possible for some functional logic to be ignored by ICL extraction. In both cases, input constraints are used to configure the circuit such that ICL extraction succeeds. An ICL attribute named “`tessent_variant_id`” takes the `variant_id` value for the current design ICL module.

Examples

Example 1

The following example shows the use of the `extract_icl` command directly following the `process_dft_specification` command.

```
SETUP> set_context dft -rtl
#commands to load design appear here
SETUP> set_current_design CoreA
SETUP> set_design_level physical_block
SETUP> set_system_mode analysis
ANALYSIS> create_dft_specification
ANALYSIS> process_dft_specification
ANALYSIS> extract_icl
```

Example 2

The following example shows the use of the `extract_icl` command as part of the “patterns -scan” context to extract the ICL network such that it can be used for test setup. For efficiency, it is recommended to extract the ICL only once after the DFT is completed, and to reuse the extracted ICL in all pattern -scan usage. ICL extraction may also not be possible after layout if the ICL modules were ungrouped during layout. The standard flow is to use the pre-layout ICL file extracted either on the RTL or netlist view for all subsequent pattern generation phases. Formal verification is typically used to verify that the functional mode, including the IJTAG network, was not affected by the layout process.

```
SETUP> set_context patterns -scan
#commands to load design and cell library appear here
SETUP> set_current_design
SETUP> extract_icl
SETUP> set_test_setup_icall myproc1
```

Example 3

In the normal flow, clock gaters are opened using either the `all_test` or the `nonscan_test` DFT signals as explained in the last section of the [Description](#) section above. If you want to enable the clock gaters using a different DFT signal, you must model the clock gater in ICL using a `ClockMux` element as shown below. The clock gater is modeled in the ICL view and if you forget to enable the clock gater and an `iClock` command is issued on a `ClockPort` in the fanout of the clock gater, the tool issues an error telling you that the clock is blocked at the clock gater as shown below.

The ICL module is defined for the clock gater cell module. It contains the ICL module attribute `use_in_icl_extraction` set to “`when_reached_by_other_modules`”. This attribute tells ICL extraction to ignore this ICL module for all clock gater instances not reached while tracing the `ClockPort` of another module.

Turning off the clock gater with a different DFT signal:

```
register_static_dft_signal_names my_clock_en -default_val_in_all_test 1
add_dft_signals my_clock_en

add_dft_control_points cgand1/FE -dft_sig my_clock_en
check_design_rules
```

extract_icl

To extract ICL when the clock gater has an ICL Clock port in its fanout, model the clock gater as follow:

```
Module cgand {
  Attribute use_in_icl_extraction = "when_reached_by_other_modules";
  ClockPort CK;
  ToClockPort GCK {
    Source mux;
  }
  DataInPort FE;

  ClockMux mux SelectedBy FE {
    1'b0 : 1'b0;
    1'b1 : CK;
  }
}
```

If an [iProc](#) calls [iClock](#) on a ClockPort that is in the fanout of the clock gater and you did not set the DFT signal `my_clock_en` to 1, the tool issues this error:

```
// Error: Unable to trace iClock 'sub1.clk' to top module input port.
// Encountered a constant ICL source connection 'cgand1.mux' while
// tracing clock source.
```

If the clock gater was not modeled in ICL, the tool would not report this issue, and the problem would only show up during simulation.

extract_inter_cell_data

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Prerequisites: The design must be flattened to the simulation model, and you must have a Layout Database opened using the [open_layout](#) command.

Extracts neighborhood cell combinations and writes the combinations out in UDFM file format.

Usage

```
extract_inter_cell_data -output_file output_filename
  [-cell_pairs {cellname1 cellname2 ...}]
  [-max_cell_pairs {max_cell_pairs_value | unlimited}]
  [-min_locations min_locations_value]
  [-strip_prefix prefix]
  [-add_prefix prefix]
  [-min_tbl min_tbl_value]
  [-placement_filter {off | horizontal | vertical}]
  [-marker_file filename]
  [-replace]
  [-list_cells]
```

Description

This command extracts neighborhood cell combinations from a [Layout Database](#) (LDB) and writes the cell combinations out to a file in UDFM file format.

Note

Using this command requires an Automotive-Grade ATPG license feature.

Tessent Log File

When running the `extract_inter_cell_data` command, the tool generates a Tessent log file. Refer to “[Example 6](#)” on page 820 for an explanation of the file’s contents.

Arguments

- **-output_file** *output_filename*
A required switch that specifies the name of the file to write the extracted inter-cell data.
- **-cell_pairs** {*cellname1 cellname2 ...*}
An optional switch and string or strings enclosed in braces ({}) that specifies one or more neighboring cell pairs to be extracted. The syntax for extracting multiple cell pairs is as follows:

```
-cell_pairs { AND2_X1 NAND3_X4 AO222_X1 AOI222_X2 }
```

In this example, the first cell pair is “AND2_X1 NAND3_X4”, and the second cell pair is “AO222_X1 AOI222_X2”.

Valid cell names are all cells that are present in the design. Note that the writing of the cell names is case-sensitive. You may also use wildcards in cases when the exact cell name is not known, or you want to extract all cells of a certain type. The syntax for using wildcards is as follows:

```
-cell_pairs { AND* OR* }
```

In this example, all cell pairs with *cellname1* beginning with “AND” and *cellname2* beginning with “OR” are extracted.

You must specify an even number of cells between the braces. When no cell pair is specified, the tool extracts all existing neighbor cell combinations. When the tool does not find the specified cells, or when a wildcard is set and the tool finds no corresponding cells, then the tool issues an error message containing the list of all existing cells.

- -max_cell_pairs *max_cell_pairs_value* | unlimited

An optional switch and integer or literal pair that specifies the maximum number of cell pairs the tool extracts from the LDB. Note that the tool sorts the cell pairs from most important to least important. When you use this command, the tool writes out the specified number of the most important cell pairs. The criteria for what is most important is based on the total bridging length (TBL) per cell pair and its number of locations (instantiations) in the design.

The default is 100,000.

- -min_locations *min_locations_value*

An optional switch to filter out cell pairs to be written to the data file.

For example, if you specify the “-min_locations 3” command and switch, the tool writes out all cell pairs instantiated at least three times. In contrast, the tool omits all other cell pairs instantiated less than three times.

The default is 1.

- -strip_prefix *prefix*

An optional switch and string pair that removes the prefix of the instance path name in the event of inconsistency in the instance names between the flat model and the LDB.

- -add_prefix *prefix*

An optional switch and string pair that adds a prefix to the instance path name in the event of inconsistency in the instance names between the flat model and the LDB.

- -min_tbl *min_tbl_value*

An optional switch and value pair that specifies the minimum total bridging length (TBL) per cell pair the tool uses during extraction from the LDB. Using this option enables filtering out cell pairs that do not meet the criteria.

The default is 0.0.

- **-placement_filter *off* | horizontal | vertical**
An optional switch and value pair that specifies the selection of horizontally or vertically neighboring cell pairs to be extracted. By default, no filter is set, that means both horizontally and vertically neighboring cell pairs are extracted.
- **-marker_file *filename***
An optional switch and string pair that generates a marker file with the specified filename and contains the specified extracted cell pairs.
- **-replace**
An optional switch that overwrites an existing file. This switch applies to both the data file and the marker file.
- **-list_cells**
An optional switch that lists all cells that are present in the netlist library as well as the LDB library of the design.

Examples

Example 1

In this example, all existing neighbor cell combinations are written to the output file named *neighborhood.data* by replacing an existing file with the same name.

```
set_context patterns -scan
read_flat_model design.flat.gz
open_layout design.ldb
// optionally, specify the set_marker_file_options marker_file_options here.

extract_inter_cell_data -output_file neighborhood.data -marker_file neighborhood.marker \
-replace
```

Example 2

In this example, all existing horizontal neighbor cell combinations are written to the output file named *horizontal_neighbors.data* by replacing an existing file with the same name.

```
extract_inter_cell_data -output_file horizontal_neighbors.data \
-placement_filter horizontal -replace
```

Example 3

In this example, all existing horizontal cell pairs of the cells named AND2_X1 and NAND3_X4 are extracted and written to the output file named *two_cells_only.data* by replacing an existing file with the same name.

```
extract_inter_cell_data -output_file two_cells_only.data -cell_pairs { AND2_X1 NAND3_X4 } \
-placement_filter horizontal -replace
```

Example 4

In this example, the 10,000 most important cell pairs are written to the output file named *top_10000_cells.data*, by replacing an existing file with the same name. The criteria of most important is based on the total bridging length (TBL) per cell pair and its number of locations (instantiations) in the design.

```
extract_inter_cell_data -output_file top_10000_cells.data -max_cell_pairs 10000 -replace
```

Example 5

In this example, all neighbor cell combinations with cell1 beginning with “AND” and cell2 beginning with “OR” are written to the output file named *AND_OR.data* by replacing an existing file with the same name. Also a list of cells containing all cells beginning with “AND” and “OR” is written to the log file.

```
extract_inter_cell_data -output_file AND_OR.data -cell_pairs {AND* OR*} -list_cells -replace
```

Example 6

The following shows an example Tessent log file that the tool generates when you issue the `extract_inter_cell_data` command:

There are three major parts to look at. The log file starts with a summary of the applied command line options followed by a distribution graph, displaying the number of required CellModelGen-runs in relation to the total bridging length (TBL) of the cell pairs.

```
extract_inter_cell_data -output_file apt1_EXT_cells_tbl0_100000.udfm \  
-marker_file apt1_EXT_cells_tbl0_100000.marker -min_tbl 0 -max_cell_pairs unlimited \  
-strip_prefix /top -list_cells -replace
```

This is followed by the list of cells (see the following example) showing an extract:

```
// Total number of library cells           : 599
// Total number of filler cells           : 32
// LADB cells: Number of cells           : 604

// -----
//   Cellname      | Type      | Active | DX (um) | DY (um) | Placements | Pins |
// -----
// xor2_08         | BOTH      | yes    | 8.16    | 4.32    | 2          | 3    |
// xor2_04         | BOTH      | yes    | 6.24    | 4.32    | 26         | 3    |

// net_01         | NETLIST   | no     | -        | -        | -          | -    |
// oai422b_01     | BOTH      | yes    | 3.36    | 4.32    | 159        | 5    |
// ...
// oai4112_12     | BOTH      | yes    | 10.08   | 4.32    | 8          | 5    |
// nor2b_12       | BOTH      | yes    | 10.08   | 4.32    | 2          | 3    |
// and3b_04       | BOTH      | yes    | 4.80    | 4.32    | 1          | 4    |
// -----

// Total number of library cell instances : 845018
// Number of considered library instances : 599
// Number of created cell pair combinations : 123942
// Number of cell pair instances          : 252133
```

The table header gives a summary of the table as follows:

```
// Total number of library cells: 599
```

This is the number of different used cells in the design that are both in Verilog and in LEF.

```
// Total number of filler cells: 32
```

This is the number of cells that are added to the layout as filler cells but are ignored, because they are not part of the Verilog file and have no function in the design.

```
// LADB cells: Number of cells: 604
```

This is the number of valid LEF cells. The difference between the number of library cells and the number of LADB cells results from cells that are only in LEF and not in Verilog, or vice versa.

The content of the table by column is as follows:

- **Cellname** — These are all Verilog cell names and all valid LEF cell names
- **Type** — This is the type of each cell
 - **NETLIST** — This cell is only defined in Verilog
 - **LEF** — This cell is only defined in the LEF files
 - **BOTH** — This cell is defined both in Verilog and in LEF

If the Type is “BOTH” then the cell names are taken into account for the cell neighbor extraction.
- **Active** — Displays if the cell name is taken into account (yes) or not (no). You can reduce the number of active cells with the command line option “-cell_pairs {cell1 cell2}”, this sets all other cells not Active.
- **DX, DY** — These are the cell dimensions in microns from the specified LEF files
- **Placements** — The number of placements of this cell from DEF
- **Pins** — The number of signal input and output pins *excluding* power/ground pins (LEF)

The table footer gives a summary of the design as follows:

```
// Total number of library cell instances : 845018
```

This is the number of occurrences of the different library cells in the design.

```
// Number of considered library instances : 599
```

This is the number of cells in the design that are considered for the cell pair creation.

```
// Number of created cell pair combinations : 123942
```

This is the number of different cell pair combinations in the design.

```
// Number of cell pair instances : 252133
```

This is the number of occurrences of the different cell pair combinations in the design.

This is followed by a cell pair distribution graph, see below example:

```

// -----
//          # CMG runs      |          # Tbl[%]
//          |          |          |          |          |

// -----

```

The number of CellModelGen runs (# CMG runs) displays the number of extracted cell pairs, in this case 123,942. The total bridging length in percent (# Tbl [%]) is a guidance to decide for how many extracted cell pairs a CellModelGen run shall be performed. For example, with 44,603 CellModelGen runs already 80.43 percent of the total bridging length is covered.

extract_sdc

Context: all contexts

Mode: all modes

Creates an SDC file that can be used for synthesis and static timing analysis (STA).

Usage

```
extract_sdc [-output_file output_file]
```

Description

This command creates SDC constraints for the current design and its sub-blocks for synthesis and static timing analysis (STA). Refer to “[Generating and Using SDC for Tessent Shell Embedded Test IP](#)” in the *Tessent Shell User’s Manual* for complete information on using SDC with Tessent Shell.

The `extract_sdc` command is run automatically as part of `extract_icl`, therefore you would not typically run this command. If you do run `extract_sdc`, it requires the design’s ICL description, DFT signals and clocks. These are all automatically loaded from the TSDB using the `read_design` command with the `-no_hdl` option.

Arguments

- `-output_file output_file`

An optional switch and file path that enables you to explicitly specify where the SDC file is written. The default location for the SDC is in the [Tessent Shell Data Base \(TSDB\)](#) at the following location:

```
dft_inserted_designs/design_name_design_id.dft_inserted_design
```

Examples

The example runs the `extract_sdc` command:

```

INSERTION> extract_sdc

// Note: Changing the context to 'patterns -ijtag'.
// -----
// Begin ICL elaboration and checking.
// -----
// ICL elaboration completed, CPU time=0.05 sec.
// -----
// Warning: Input constraint 'C0' on ICL port 'bistr_clk' is removed.
// Warning: Input constraint 'C0' on ICL port 'bistr_shift_en' is removed.
// Warning: Input constraint 'C0' on ICL port 'ijtag_sel' is removed.
// Warning: Input constraint 'C0' on ICL port 'ijtag_ue' is removed.
// Warning: Input constraint 'C1' on ICL port 'ijtag_reset' is removed.
// Writing SDC file:
./tsdb_outdir/dft_inserted_designs/blockB_rtl.dft_inserted_design/
blockB.sdc

```

[Delaying Clock Pulses in Shift and Capture to Handle Slow Scan Enable Transitions](#)

filter_collection

Context: unspecified, all contexts

Mode: all modes

Filters a previously created collection, resulting in a new collection.

Usage

`filter_collection base_collection expression [-regex] [-nocase]`

Description

Filters a previously created collection, resulting in a new collection.

In many cases, the commands that create collections support a `-filter` option, which performs filtering as part of the collection process. Usually this is a more efficient method of filtering. However, you may want to use the `filter_collection` command if you are filtering a large collection multiple times with different criteria.

The `filter_collection` command results either in a new collection that contains a subset of the objects in the input `base_collection`, or in an empty collection, which indicates that the expression filtered out all elements of the input `base_collection`.

Arguments

- ***base_collection***
A required string that specifies the base collection to be filtered. This collection is copied to the resulting collection, and objects are removed if they are evaluated as false by the conditional expression.
- ***expression***
A required string that specifies an expression with which to filter the collection. The attributes used within the equation must exist for the object types contained in the collection. Otherwise, an error is generated. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The `=~` and `!~` matching operators use simple wildcard matching versus Posix extended regular expression based on the presence of the `-regex` option.
- **`-regex`**
An optional switch that directs the matching patterns as a regular expression instead of as a simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.
- **`-nocase`**
An optional switch that specifies that the pattern match is case insensitive.

Examples

Example 1

The following example creates a collection of instances of type design.

```
set var [filter_collection [get_instances *] {type == "design"}]  
{Adder1 Adder2}
```

Example 2

The following example starts with a collection of all instances and filters the collection based on an attribute_equality of user-defined attributes.

```
set var [filter_collection [get_instances] {myType1 || myType2 == "ABC"}]
```

The above example is equivalent to this:

```
set var [get_instances -filter {myType1 || myType2 == "ABC"}]
```

find_design_names

Context: all contexts

Mode: setup, analysis

Displays design object hierarchical names matched by an input string, which may include asterisk (*) or question mark (?) wildcard characters.

Usage

```
find_design_names name_pattern [-LOcal | -Hier]  
[-Design | -NETList | -Library | -All]  
[-INStance | -Net | -Pin [INPut | OUtput | INOut | ALLIn | ALLOut] |  
[[-Cell | -Module] -LISt_references]]  
[> | >>] file_pathname
```

Description

Displays design object hierarchical names matched by an input string, which may include asterisk (*) or question mark (?) wildcard characters.

Note

 The get_* Tessent Shell commands include additional features, including the capability to search with regular expressions, without regard to case, and so on. Consider using these commands unless you have a specific need for find_design_names.

Arguments

- ***name_pattern***
A required string, which may include asterisk (*) or question mark (?) wildcard characters.
- **-LOcal**
An optional switch that matches wildcard characters within the current hierarchy level.
- **-Hier**
An optional switch that matches the regular expression across hierarchy boundaries (for example, a* matches a1/b/c). This is the default.
- **-Design**
An optional switch that matches only pathnames to objects at the topmost library cell level.
- **-NETList**
An optional switch that matches objects from the top of the design down to the topmost library cell.
- **-Library**
An optional switch that matches objects within any level of library cells.

- **-All**
An optional switch that specifies matches objects at all levels of the design. This is the default.
- **-INStance**
An optional switch that matches only instance pathnames. This is the default.
- **-Net**
An optional switch that matches only net pathnames.
- **-Pin**
An optional switch that matches only pin pathnames (any pin direction). The following optional pin filters restrict which pins are matched:
 - INPut — Match only input pin pathnames.
 - OUtput — Match only output pin pathnames.
 - INOut — Match only bidirectional pin pathnames.
 - ALLIn — Match both input and bidirectional pin pathnames.
 - ALLOut — Match both output and bidirectional pin pathnames.
- **-Cell**
An optional switch that finds all library cell (model) names matching the specified regular expression.
- **-Module**
An optional switch that finds all netlist module names matching the specified regular expression.
- **-LISt_references**
An optional switch for use with **-Cell** or **-Module** that lists the pathnames of all instances in the current design that reference each cell or module matching the regular_expression.
- **> file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- **>> file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following examples display object pathnames for various input wildcard strings, given a netlist with the following instance hierarchy:

```
/
  tiny_i
    U5
  ret_i
    intreg1_reg_0 ... intreg1_reg_31
    add_20
      U1_0 ... U1_3
    add_30
      U5 ... U12
    mul_18
      U5 ... U868
      FS
        U5 ... U33
    mul_19
      FS
        U5 ... U278
        U5 ... U181
    mul_22
      U5 ... U735
      FS
        U15 ...
```

and assuming the U5 instances all reference the following library cell:

```
model LSR2BUFA(Q, QN, S, R, G, SD, RD) (
  input(S, R, G, SD, RD) ()
  output(Q) (primitive = _buf UP1 (QT, Q);)
  output(QN) (primitive = _buf UP2 (QNT, QN);)
  intern(QT_int) (instance = LSI_LSR2 UD1 (QT_int, S, R, G, SD, RD);)
  intern(QNT_int) (instance = LSI_LSR2N UD2 (QNT_int, S, R, G, SD, RD);)
  intern(QT) (instance = LSI_NOTI UD3 (QT, QT_int);)
  intern(QNT) (instance = LSI_NOTI UD4 (QNT, QNT_int);)
)
```

Example 1

find_design_names /ret_i/add_2* -instance -design -hier

```
// Note: Matched 4 names
/ret_i/add_20/U1_0
/ret_i/add_20/U1_1
/ret_i/add_20/U1_2
/ret_i/add_20/U1_3
```

Example 2

find_design_names /ret_i/add_2* -instance -netlist -hier

```
// Note: Matched 5 names
/ret_i/add_20
/ret_i/add_20/U1_0
/ret_i/add_20/U1_1
/ret_i/add_20/U1_2
/ret_i/add_20/U1_3
```

Finds instance `add_20` under `/ret_i/`, and also descends the hierarchy to find all netlist instances under `/ret_i/add_20/`.

Example 3

```
find_design_names /ret_i/add_2* -inst -netlist -local
```

```
// Note: Matched 1 names
/ret_i/add_20
```

This example shows that `-Local` does not descend the hierarchy to find more matches as the previous example does.

Example 4

```
find_design_names /ret_i/add_2* -ins -design -local
```

```
// Note: Matched 0 names
```

There are no instances of a library cell under `/ret_i/` with instance name starting with `add_2`.

Example 5

```
find_design_names /ret_i/*_2? -ins -netlist -local
```

```
// Note: Matched 2 names
/ret_i/add_20
/ret_i/mul_22
```

Found 2 instances under `/ret_i/`.

Note

 `/ret_i/gt_68_2` did not match because the “?” in the wildcard expression requires another character after the “_2”.

Example 6

```
find_design_names */U5 -inst -design -hier
```

find_design_names

```
// Note: Matched 7 names
/tiny_i/U5
/ret_i/add_20/U5
/ret_i/mul_18/U5
/ret_i/mul_18/FS/U5
/ret_i/mul_19/U5
/ret_i/mul_19/FS/U5
/ret_i/mul_22/U5
```

Example 7

```
find_design_names ret_i/mul*/U5 -ins -des -local
```

```
// Note: Matched 3 names
/ret_i/mul_18/U5
/ret_i/mul_19/U5
/ret_i/mul_22/U5
```

Example 8

```
find_design_names ret_i/mul*/U5 -ins -design -hier
```

```
// Note: Matched 5 names
/ret_i/mul_18/U5
/ret_i/mul_18/FS/U5
/ret_i/mul_19/U5
/ret_i/mul_19/FS/U5
/ret_i/mul_22/U5
```

Example 9

```
find_design_names ret_i/mul_18/U5* -ins -library -hier
```

```
// Note: Matched 5 names
/ret_i/mul_18/U5
/ret_i/mul_18/U5/UD1
/ret_i/mul_18/U5/UD2
/ret_i/mul_18/U5/UD3
/ret_i/mul_18/U5/UD4
```

Example 10

```
find_design_names ret_i/mul*/U5/* -pin output -design -local
```

```
// Note: Matched 6 names
/ret_i/mul_18/U5/Q
/ret_i/mul_18/U5/QN
/ret_i/mul_19/U5/Q
/ret_i/mul_19/U5/QN
/ret_i/mul_22/U5/Q
/ret_i/mul_22/U5/QN
```

Example 11

```
find_design_names * -mod -list_references
```

```
// Note: Found 3 netlist modules
// Note: Instances of netlist module or_gate
/o1
/o2
// Note: Instances of netlist module pme_caam_RC_CG_MOD_335839
/RC_CG_HIER_INST3921
```

Example 12

find_design_names * -cell -list

```
// Note: Found 6 library cells
// Note: Instances of library cell HD45_SZ_MUX21X2
/mux
// Note: Instances of library cell HD45_SZ_LDLRX2
// Note: Instances of library cell HD45_SH_OR2X2
/o1/foo
/o2/foo
// Note: Instances of library cell HD45_SV_CNHLSX4
/RC_CG_HIER_INST3921/RC_CGIC_INST
// Note: Instances of library cell HD45_SH_SDFPRQX4
/data_out_reg_0
/data_out_reg_1
/data_out_reg_2
/data_out_reg_3
/data_out_reg_4
/data_out_reg_5
/shadow
/non_scan
```

foreach_in_collection

Context: unspecified, all contexts

Mode: all modes

Iterates over each element in a collection.

Usage

```
foreach_in_collection itr_var collection {body}
```

Description

Iterates over each element in a collection.

You cannot use the Tcl-supplied `foreach` command to iterate over collections because `foreach` operates on a Tcl list, and a collection is not a Tcl list but a pointer to an array of data on the C++ side. You can use the `get_name_list` command to convert the collection of objects into a Tcl list of object names, but you should avoid doing this if the collection is very large or if the object names are not unique, such as port names. For example, a port object is a specific port name on a specific module. Specifying just the name of the port does not indicate which module it belongs to.

You can nest the `foreach_in_collection` command within other control structures, including `foreach_in_collection`.

A collection remains in memory for as long as it is referenced by a Tcl variable. A collection is deleted once it is no longer referenced by any Tcl variable. If you make the mistake of using the Tcl command `foreach` to iterate on a collection, the command has the negative side effect of de-referencing the collection and may destroy it. Always use `foreach_in_collection` to iterate on the elements of a collection.

Arguments

- ***itr_var***

A required string that specifies the name of a Tcl variable. During each iteration, `itr_var` holds a string pointer to a collection of exactly one object.

- ***collection***

A required value that specifies a collection over which to iterate. It may be the content of a Tcl variable that points to a collection or the result of an introspection command that generates a collection. Note, just like the Tcl `foreach` command, a snapshot of the collection is taken before the first iteration. This means that even if the `append_to_collection` command is used to increase the size of the collection as part of the iterations, the `foreach_in_collection` command does not see the newly added elements. Example 3 shows how to collect new elements into a separate collection and use a Tcl `while` command to repeat the loop until the collection is truly empty.

- *body*

A required string that specifies a script to run per iteration. The entire body must be enclosed within a set of braces.

Examples

Example 1

The following example connects a set of pins that has a special attribute called myAtt set to True to a net that has the same name as the pin. If not already present, the net is created. Note that the example assumes that all pins are scalar objects. Extra code would be needed to deal with bused pins and create the entire bused nets with one command. The is_bus and other built-in bus attributes are available to do this efficiently. Note how the lindex command converts the return value of the get_attribute_value_list command into a string so that it can be used to construct the net name using \${parent}/\${leaf}.

```
foreach_in_collection pin [get_pins -filter "myAtt"] {
    set leaf [lindex [get_attribute_value_list $pin -name leaf_name] 0]
    set parent [lindex [get_attribute_value_list $pin -name parent_instance] 0]
    if {[sizeof_collection [get_nets ${parent}/${leaf} -silent]] = 0} {
        create_net ${parent}/${leaf}
    }
    create_connections $pin ${parent}/${leaf}
}
```

Note how filtering based on the value of an attribute is performed to reduce the size of the collection on which to iterate. The user could have chosen to loop on all pins and check inside the loop if the myAtt attribute is set to true, but this is very inefficient because filtering is done in C++ as opposed to looping in Tcl.

```
#inefficient use of looping. Best to filter collection before looping on
#it as shown above.
```

```
foreach_in_collection pin [get_pins] {
    if {[get_attribute_value_list $pin -name myAtt]} {
        set leaf [lindex [get_attribute_value_list $pin -name leaf_name] 0]
        set parent [lindex [get_attribute_value_list $pin -name parent_instance] 0]
        if {[sizeof_collection [get_nets ${parent}/${leaf} -silent]] = 0} {
            create_net ${parent}/${leaf}
        }
        create_connections $pin ${parent}/${leaf}
    }
}
```

Example 2

The following example loops on a collection of pins and deletes them. The same pin object is added twice into the collection being looped on to illustrate the fact that obsolete objects are still looped on and that a -silent switch must be used so that they are ignored by the delete_pin command. Without the -silent option, an error would be generated the second time the pin object u1/P2 was looped on.

```

set my_pins [get_pins {u1/P2 u1/P*}]
puts "my_pins are [get_name_list $my_pins]"
foreach_in_collection pin $my_pins {
  delete_pin $pin -silent
}

```

```
my_pins are u1/P2 u1/P1 u1/P2 u1/P3
```

Example 3

The following example shows how to iterate on a collection of objects until no objects are left to process. The procedure called “proc_that_returns_new_objects” is called on each object and may return new objects to process. The “append_to_collection col” command cannot be used to process the new objects because the foreach_in_collection command took a snapshot of “col” before the first iteration. Instead, the new objects are collected into a collection variable called “newCol” and it is assigned back to “col” after the foreach_in_collection command is done. The loop is repeated for as long as “newCol” is not empty after the foreach_in_collection command has completed.

```

set col [<start collection>]
while {[sizeof_collection $col] > 0} {
  set newCol {}
  foreach_in_collection obj $col {
    append_to_collection newCol [proc_that_returns_new_objects $obj]
  }
  set col $newCol
}

```

format_dictionary

Context: all including the unspecified one

Mode: all

Generates a Tcl dictionary in a human-readable format.

Usage

```
format_dictionary dictionary [-left_indent left_indent]  
    [-keys_that_are_strings keys_that_are_strings]  
    [-keys_that_are_lists keys_that_are_lists]  
    [-list_elements_per_line {1 | all}]  
    [-variable_name variable_name]  
    [-banner string]  
    [-preserve_collection_pointers]
```

Description

Generates a Tcl dictionary in a human-readable format. The dictionary consists of entries on separate lines with child elements indented by two white spaces relative to their parents entries.

By default, elements are considered sub-dictionaries if they contain an even number of elements. Otherwise, they are considered lists.

You can send the content of the dictionary to a file by using the `-variable_name` option.

Arguments

- **dictionary**
A string that defines a Tcl dictionary similar to the one created using the Tcl `dict` command or the one returned by the `get_design_sources -file_dictionary` command.
- `-left_indent left_indent`
An optional switch and value pair that controls the indentation of the dictionary, where the value is a positive integer. When specified, the tool adjusts the entire dictionary left by the specified `left_indent` value, maintaining child element indentation.
- `-keys_that_are_strings keys_that_are_strings`
An optional switch and value pair that specifies to treat the specified leaf names of keys as strings. By default, if a string contains an even number of words, the tool treats it as a sub-dictionary. If a string contains an odd number of words, the tool considers it a list that you can control with the `-list_elements_per_line` option. When you mark a key as holding the value of a string, the string is shown inside quotation marks.
- `-keys_that_are_lists keys_that_are_lists`
An optional switch and value pair that specifies to treat the specified leaf names of keys as lists. By default, if a list contains an even number of elements, the tool treats it as a sub-dictionary. When you mark a key as holding the value of a list, the list is shown inside

braces ({}). You can control the number of elements to display per line with the `-list_elements_per_line` option.

- `-list_elements_per_line 1 | all`
An optional switch that specifies the number of elements from a list to display on each line. By default, the entire list displays on a single line. Specify 1 to display one element per line. The tool treats the value of a key as a list when it contains an odd number of elements or it is specified by the `-keys_that_are_lists` option.
- `-variable_name variable_name`
An optional switch that specifies the name of a Tcl variable. When specified, the formatted dictionary is included in a “`set variable_name {}`” wrapper, which the tool displays in the transcript. When you specify *variable_name* with a redirection symbol (`>`) and a filename, the tool sends the dictionary to the specified file.
- `-banner string`
An optional switch and string pair that specifies a banner text that can be passed as a string, which can contain newlines.
- `-preserve_collection_pointers`
An optional switch that preserves the collection indexes (`@<integer>`). By default, a value that is a collection is considered a list.

Examples

The following example uses the Tcl `dict` command to create a Tcl dictionary then shows how it looks raw versus how it looks when formatted with the `format_dictionary` command.

The last invocation shows how to use the command to export the dictionary to file in a human-readable manner.

```
> dict set mydict square1 color red
> dict set mydict square1 dimensions width 3
> dict set mydict square1 dimensions height 5
> dict set mydict square1 usage "for learning"
> dict set mydict square1 partners {round triangle line point}
> puts $mydict
square1 {color red dimensions {width 3 height 5} usage {for learning}
partners {round triangle line point}}
> puts [format_dictionary $mydict]
square1 {
  color red
  dimensions {
    width 3
    height 5
  }
  usage {
    for learning
  }
  partners {
    round triangle
    line point
  }
}

> puts [format_dictionary $mydict -keys_that_are_list partners]
square1 {
  color red
  dimensions {
    width 3
    height 5
  }
  usage {
    for learning
  }
  partners {round triangle line point}
}
> puts [format_dictionary $mydict -keys_that_are_list partners
-list_elements_per_line 1]
square1 {
  color red
  dimensions {
    width 3
    height 5
  }
  usage {
    for learning
  }
  partners {
    round
    triangle
    line
    point
  }
}
> format_dictionary $mydict -keys_that_are_list partners
-list_elements_per_line 1 -variable_name mydict > mydict.txt
> cat mydict.txt
set mydict {
```

```
square1 {  
  color red  
  dimensions {  
    width 3  
    height 5  
  }  
  usage {  
    for learning  
  }  
  partners {  
    round  
    triangle  
    line  
    point  
  }  
}  
}
```

get_attribute_list

Context: unspecified, all contexts

Mode: all modes

Returns an alphabetically sorted Tcl list of attribute names.

Usage

Usage 1: List attributes specified on a group of objects

```
get_attribute_list obj_spec [-predefined | -user_defined] [-silent]
```

Usage 2: List attributes registered for a groups of object types

```
get_attribute_list -object_types type_list [-predefined | -user_defined] [-silent]
```

Usage 3: List all registered attributes

```
get_attribute_list [-predefined | -user_defined] [-silent]
```

Description

Returns an alphabetically sorted Tcl list of attribute names.

- **Usage 1** — Returns the attributes set on any object found in *obj_spec*.

The attributes on an object inherited from an associated object are reported. For example, an attribute registered for the module object type and set on a given module object are reported in the list of attributes for the instances of that module. By default, attributes that have not been set on the objects are not listed unless the attribute was registered with the `-show_default` option.

If an object in *obj_spec* does not exist, an error message displays unless the `-silent` switch is specified.

- **Usage 2** — Returns the attributes registered for all specified object types.

These do not include the inherited attributes from one object type to another such as the module attribute inherited by the associated instances.

- **Usage 3** —Returns all registered attributes.

In all three usages, only predefined attributes are returned when the `-predefined` option is specified. Only user-defined attributes are returned when the `-user_defined` option is specified.

Arguments

- *obj_spec*

A required value used in Usage 1 that specifies an object name, a Tcl list of object names, or a collection of objects.

get_attribute_list

- **-object_types *type_list***

A required switch and value pair used in Usage 2 that enumerates the object types for which the attribute list is requested. The currently supported object types are module, port, instance, pin, net, and icl_module. The list of supported object types is augmented in successive releases, and, eventually, all object types are available for introspection.

- **-predefined | -user_defined**

An optional switch that constrains the returned list to only pre-defined attribute names or only user-defined attribute names. If this argument is not specified, by default no constraints are applied and both pre-defined and user-defined attributes are returned.

- **-silent**

An optional switch that specifies to suppress error messages if there are objects in the *obj_spec* that do not exist.

Examples

Example 1

The following example lists the attributes set on three pins:

```
get_attribute_list {tiny1_3/d1 tiny1_3/d2 tiny1_3/d3}
base_name direction has_functional_source is_hard_module is_valid
leaf_name library_name master_module_name module_name name object_type
parent_instance parent_is_hard_module tie_value
```

Example 2

The following example shows the impact of using the **-show_default** switch, when registering an attribute, on the **get_attribute_list** command:

```
register_attribute -name a1 -value_type boolean -object_types pin
get_attribute_list {u1/pin1 u1/pin2} -user_defined
{ }
```

```
register_attribute -name a2 -value_type boolean -object_types pin -show_default
get_attribute_list {u1/pin1 u1/pin2} -user_defined
a2
```

```
set_attribute_value u1/pin1 -name a1
{u1/pin1}
```

```
get_attribute_list {u1/pin1 u1/pin2} -user_defined
a1 a2
```

get_attribute_option

Context: unspecified, all contexts

Mode: all modes

Retrieves the current setting of an attribute's option.

Usage

```
get_attribute_option -name attribute_name -object_type type_name  
    {-export_during_write  
    | -preserve_boundary_in_flat_model  
    | -applies_to_child_instances  
    | -display_in_gui  
    | -gui_marking_index}
```

Description

Retrieves the current setting of an attribute's option.

The `get_attribute_option` command returns a string with the option settings of the specified attribute. These options can be modified after the attribute has been registered using the [set_attribute_options](#) command.

Arguments

- **-name** *attribute_name*
A required switch and value pair that specifies the name of the attribute whose option values are to be returned.
- **-object_type** *obj_type*
A required switch and value pair that specifies the object type whose attribute option settings are to be returned.
- **-export_during_write**
An optional switch that retrieves the current value of the `export_during_write` option for the specified attribute name on the specified object type. For more information on the `-export_during_write` switch, see the [set_attribute_options](#) command.
- **-preserve_boundary_in_flat_model**
An optional switch that retrieves the current value of the `-preserve_boundary_in_flat_model` option for the specified attribute name on the specified object type. For more information on the `-preserve_boundary_in_flat_model` switch, see the [set_attribute_options](#) command.
- **-applies_to_child_instances**
An optional switch that retrieves the current value of `-applies_to_child_instances` for the specified attribute name on the specified object type. For more information on the `-applies_to_child_instances` switch, see the [set_attribute_options](#) command.

- **-display_in_gui**
An optional switch that retrieves the current value of the `-display_in_gui` option for the specified attribute name on the specified object type. For more information on the `-display_in_gui` switch, see the [set_attribute_options](#) command.
- **-gui_marking_index**
An optional switch that retrieves the current value of the `-gui_marking_index` for the specified attribute name on the specified object type. For more information on the `-gui_marking_index` switch, see the [set_attribute_options](#) command.

Examples

The following example retrieves the `-applies_to_child_instances` setting for the attribute named `my_power_domain` that is registered for the instance object type:

```
get_attribute_option -name my_power_domain -object_type instance \  
-applies_to_child_instances  
  
on
```

get_attribute_value_list

Context: unspecified, all contexts

Mode: all modes

Retrieves the value of an attribute on the specified design objects.

Usage

```
get_attribute_value_list object_spec -name attribute_name [-is_specified] [-silent]
```

Description

Retrieves the value of an attribute on the specified design objects.

Like all other Tessent commands ending with an `_list` suffix, this command returns a list with all the values set for the attribute on each of the objects in *object_spec*. This is also the case when you pass one object. You can use `lindex` or a `foreach` loop to return the single values.

If an object in *object_spec* does not exist, or if the attribute specified by *attribute_name* does not exist on the design object, an error message displays unless the `-silent` switch is specified.

This command is used to introspect attributes on all object types. When *object_spec* is a Tcl list of names, the object types are queried in a specific order until one of the data models has the object by the requested name. Use “`get_attribute_value_list [get_XXX YYY]`” when you want to see the attributes of object named `YYY` of type `XXX`.

For example, the design may have a pin named `u1/p1` and a net by the same name. To query the attributes of the net object, use the following:

```
get_attribute_value_list [get_nets u1/p1]
```

If you use the following:

```
get_attribute_value_list u1/p1
```

then the tool returns the attributes of the pin object because the pin object model is queried before the net object model.

The object data model types are queried in the following order:

1. module
2. instance
3. port
4. pin
5. net
6. pseudo_port

7. gate_pin
8. icl_module
9. icl_instance
10. icl_instance_in_module
11. icl_port
12. icl_pin
13. icl_pin_in_module
14. icl_scan_interface_of_module
15. icl_scan_interface
16. icl_scan_register_in_module
17. icl_scan_register
18. icl_scan_mux_in_module
19. icl_scan_mux
20. icl_one_hot_scan_group_in_module
21. icl_one_hot_scan_group
22. icl_alias_in_module
23. icl_alias
24. config_wrapper
25. config_property
26. config_repeatability_property
27. config_data_wrapper
28. config_csv_wrapper

Arguments

- ***object_spec***

A required value that specifies a collection of one or more objects.

It is also legal to supply a Tcl list of one or more object names, although this is not recommended for the following reasons:

- Objects of different types can have the same name, which can lead to confusion.
- Objects found may not support the requested attribute, which can generate an error.

- For types that accept escaped identifiers, using such a name may not find the object at all. For example, using an escaped port name like `{\nport }` with “`get_single_attribute_value [list {\nport }]` ...]” finds nothing. This is because escaping is not necessary for a port name that is valid without escaping. For that specific example, you should use “`get_ports [list {\nport} -use_path_matching_options`”, and then pass the resulting collection object to the `get_single_attribute_value` command.
- **-name *attribute_name***
A required switch and string pair that specify the name of the attribute whose value is to be returned.
- **-is_specified**
An optional Boolean switch that returns 1 when the attribute was explicitly set on the object otherwise a 0 is returned. When an attribute is unspecified, its value is derived from different criteria. Instance level attributes where `get_attribute_option -apply_to_child_instances` returns true inherit their value from their parent instance. If the instance does not have a parent instance, then its default value is used. Attributes that do not support inheritance always have their default value when unspecified.
- **-silent**
An optional switch that specifies to suppress error messages if an object in *object_spec* does not exist, or if the attribute specified by `attribute_name` does not exist for a given design object.

Examples

Example 1

The following example returns the value of `parent_instance` value for pins. The `get_attribute_value_list` command returns a Tcl list of values even if there is only one object in `obj_spec`. Use `index` as shown below to convert any one element list into a string that you can then concatenate with other strings to create object names. The 0 argument to the `index` command below takes the first (and only) element of the list.

```
get_attribute_value_list u1/u5/u8/ABC -name parent_instance
```

```
u1/u5
```

```
get_attribute_value_list u1/DEF -name parent_instance
```

```
{ }
```

```
index [get_attribute_value_list u1/DEF -name parent_instance] 0
```

Example 2

The following example retrieves values for the attribute named “is_hard_module” on the listed modules.

```
get_attribute_value_list {alu mux2 rom3} -name is_hard_module  
false true false
```

```
set myList {mux2 alu}  
get_attribute_value_list $myList -name is_hard_module  
true false
```

get_attributed_objects

Context: unspecified, all contexts

Mode: all modes

Retrieves the complete collection of objects matching one of the specified object type lists and having one of the attributes found in the *attribute_name_list* specified on the object.

Usage

`get_attributed_objects -attribute_names attribute_name_list -object_types type_list`

Description

Use this command to return the complete collection of objects matching one of the specified object type list and having one of the attribute found in the *attribute_name_list* specified on the object.

This command works for any user-defined attributes and is much more efficient than getting the full collection of objects of a given type and filtering full collection based on attributes. For example, a design may have 5 millions pins but only 200 with the given attribute specified on it. Instead of filtering a 5 million object collection to find the 200 elements you care about, the commands constructs the collection directly from the attribute table.

There are two types of attributes: access attributes and storage attributes. Access attributes are attributes that reflect the value of a property from an internal data model. For example, the direction attribute of a pin is an access attribute. It reflects the direction of the pin as stored in the design database. A storage attribute on the other hand is not attached to an internal data structure. A dedicated hash table is created to store information about an object. All attributes you register with the [register_attribute](#) command are storage attribute. Most attributes not registered by you are access attribute.

The `get_attributed_objects` command only works with storage attributes. If you specify the name of an access or other unsupported attribute with the `-attribute_names` switch, the tool issues an error message. Use the “[report_attributes -name attribute_name](#)” command if you are not sure about an attribute. The command returns “Class : pre-defined vs user-defined”. When it returns “user-defined”, you can use this attribute with the `get_attributed_objects` command.

Arguments

- **-attribute_names *attribute_name_list***

A switch-value pair used to specify a list of attribute names. The attribute names must be user-defined registered attributes for all the specified object types.

- **-object_types *type_list***

A switch-value pair used to specify a list of object types for which you want its attributes objects.

Examples

The following example looks for all pin or port objects with the xyz_function attribute specified:

```
set attributed_objects [get_attributed_objects -attribute_names xyz_function -object_types {port pin}]
```

This example is part of “[Example 4](#)” on page 1521 in the [register_drc](#) command section. Refer to this example for the context of its usage.

get_auxiliary_pins

Context: dft, patterns

Mode: setup, analysis, insertion

Returns the input or output data or enable auxiliary pins associated to ports

Usage

```
get_auxiliary_pins port_spec [-direction {input |output}] [-enable] [-exists] [-silent]
```

Description

An introspection command used to get the auxiliary pins associated to a port. The auxiliary pin information is automatically available when the auxiliary logic is created using the [AuxiliaryInputOutputPorts](#) wrapper of the [BoundaryScan](#) or [EmbeddedBoundaryScan](#) wrapper of the [DftSpecification](#). As can be seen in [Figure 10-36](#) on page 3886 of the [AuxiliaryInputOutputPorts](#) wrapper section, the multiplexer used to inject the auxiliary output data on an output or inout pad is done on the test side of the Output JTAG multiplexer to avoid cascading two multiplexers along the functional path. This is why when you implement boundary scan for your design, you must also implement the auxiliary data logic at the same time. If you are not using Boundary Scan in your design, you can still implement the auxiliary data logic using a [DftSpecification](#) wrapper that looks similar to the following:

```
read_config_data -from_string {
  DftSpecification(corea,rtl2) {
    BoundaryScan {
      BoundaryScanCellOptions {
        * : no_bscan_cell;
      }
      AuxiliaryInputOutputPorts {
        auxiliary_input_ports : gpio[11:4];
        auxiliary_output_ports : gpio[7:0];
      }
    }
  }
}
process_dft_specification
```

If you are implementing the auxiliary logic manually or with a third-party tool, you can describe the mapping between the top-level ports and the auxiliary data pins using a Tcl dictionary called “::auxiliary_data_dict” that uses the following format:

```
<port_name> {
  auxiliary_output_pin      <pin_name>
  auxiliary_output_enable_pin <pin_name>
  auxiliary_input_pin       <pin_name>
  auxiliary_input_enable_pin <pin_name>
}
... #repeat for all ports
```

You can use the Tcl “dict” command to populate this dictionary once and access the information using the `get_auxiliary_pins` command afterward. The following is an example of how to use

the Tel “dict” command to set the `auxiliary_data_input` entry for the port “`gpio[1]`” in the dictionary:

```
dict set ::auxiliary_data_dict gpio[1] auxiliary_input_pin u1/aux_in1
```

Arguments

- *port_spec*
A required string-value pair specifying a Tel list of port names or a collection containing port objects.
- `-direction {input |output}`
An optional switch-value pair specifying if the input or output data logic of the port is requested. Only inout ports can have both input and output auxiliary logic. When unspecified, the switch defaults to input.
- `-enable`
An optional Boolean switch used to request the enable pin, instead of the data pin, for the specified auxiliary logic direction.
- `-exists`
An optional Boolean switch used to request the existence of the auxiliary logic pin instead of the pin object itself. A 1 is returned when the requested input/output data/enable auxiliary pin exists, otherwise a 0 is returned
- `-silent`
An optional Boolean switch that suppresses the error message that is normally generated when the command is called without the `-exists` switch and the requested input/output data/enable auxiliary pin does not exist. Instead, an empty collection is silently returned.

Examples

The following example uses the `get_auxiliary_pins` command to get the auxiliary input and output data pins of specific ports and use their names to populate the `port_pin_name` properties found within the [EdtChannelsIn/EdtChannelsOut](#) wrappers of the [EDT DftSpecification](#) wrapper.

get_auxiliary_pins

```

set_spec [create_dft_spec -sri_sib_list {occ}]
read_config_data -in_wrapper $spec -from_string {
  Edt {
    ijtag_host_interface : Sib(edt);
    Controller(c1) {
      longest_chain_range           : 10, 50;
      scan_chain_count              : 40;
      input_channel_count           : 2;
      output_channel_count          : 1;
      connect_bscan_segments_to_lsb_chains : on;
      Connections {
        EdtChannelsIn(1) {
        }
        EdtChannelsIn(2) {
        }
        EdtChannelsOut(1) {
          Pipelinestage {
          }
        }
      }
    }
  }
}
set_config_value port_pin_name \
-in $spec/Edt/Controller(c1)/Connections/EdtChannelsIn(0) \
[get_single_name [get_auxiliary_pins gpio[0] -direction input]]
set_config_value port_pin_name \
-in $spec/Edt/Controller(c1)/Connections/EdtChannelsIn(1) \
[get_single_name [get_auxiliary_pins gpio[1] -direction input]]
set_config_value port_pin_name \
-in $spec/Edt/Controller(c1)/Connections/EdtChannelsOut(0) \
[get_single_name [get_auxiliary_pins gpio[2] -direction output]]

```

get_boundary_scan_port_option

Context: dft, patterns

Mode: all modes

Returns the cell_options defined on the specified port, or the specified pin_order_file name, or the pad_io_ports collection.

Usage

```
get_boundary_scan_port_option {port_spec -cell_options | -packed_pin_name |  
-pin_order_file | -pad_io_ports}
```

Description

Returns the cell_options defined on the specified port, or the specified pin_order_file name, or the pad_io_ports collection.

Arguments

- ***port_spec***
A required string that specifies the name of a port or a collection containing a single port.
- **-cell_options**
A Boolean that queries the cell options that were previously specified on the given port using the “[set_boundary_scan_port_options -cell_options](#)” command.
- **-packed_pin_name**
A Boolean option that queries the device package pin names previously specified with the “[set_boundary_scan_port_options -packed_pin_name <port_name_list>](#)” command.
- **-pin_order_file**
A Boolean option that queries the previously specified pin_order_file name using the “[set_boundary_scan_port_options -pin_order_file](#)” command.
- **-pad_io_ports**
A Boolean option that queries the previously specified collection of pad_io ports using the “[set_boundary_scan_port_options -pad_io_ports](#)” command.

Examples

The following example requests the cell_options that were previously specified on the port dac_out.

```
set_boundary_scan_port_option dac_out -cell_options analog
```

```
get_boundary_scan_port_option dac_out -cell_options
```

```
analog
```

[report_boundary_scan_port_options](#)

[set_boundary_scan_port_options](#)

get_bundle_objects

Context: all contexts

Mode: all modes

Returns a collection of bundle/leaf objects in the current design specified by the `name_patterns` list in conjunction with the specified options. Those bundle (leaf in case of descendants) objects are ancestors or descendants of the objects that match the specified `name_patterns` depending upon the specified options.

Usage

```
get_bundle_objects [name_patterns]  
  -of_objects of_objects  
  [-parent | -children | -root | -leaf]  
  [-filter attribute_equation]  
  [-regexp]  
  [-nocase]  
  [-silent]
```

Description

When the `name_patterns` list is omitted, the tool returns all parent and child complex signal bundle objects subject to filtering imposed by the options you specify.

For complete usage information, see “[Bundle Object Introspection](#)” in the *Tessent Shell User’s Manual*.

Arguments

- `name_patterns`
An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of bundle objects. The string is a Tcl list of patterns separated by spaces and enclosed in braces (`{}`). If no `name_patterns` are specified, the tool searches all bundle objects. The `name_patterns` are not permitted to include slashes, which are hierarchy separator symbols. See “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a complete description of the pattern syntax when the `-regexp` option is used and not used.
- `-of_objects of_objects`
A switch and Tcl list of connective objects or a collection of one or more connective objects. A connective objects are one or more port, port_bundle, pin, pin_bundle, net, or net_bundle objects.

- -parent | -children | -root | -leaf

An optional switch that specifies which bundle objects to return. Choose one from the following:

- parent — Returns the parent bundle of the object. With this option, you can introspect the ancestors of the selected objects.
- children — Returns the child bundles of the objects, which permits you to introspect the descendants of the selected objects.
- root — Returns the top-level bundle.
- leaf — Returns the leaf objects of the bundle (port_bundle -> port, pin_bundle -> pin, net_bundle -> net).

- -filter *attribute_equation*

An optional switch value pair that filters the introspection results using the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the port, pin, net, port_bundle, pin_bundle, or net_bundle object types. See section “Attribute Filtering Equation Syntax” for more details on filtering attribute equation format. The =~ and !~ matching operators used simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option or not.

- -regexp

An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a regular expression instead of as a simple wildcard pattern. See section “Glob and Regular Expression Pattern Matching Syntax” for a description of the regular expression syntax.

- -nocase

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for nets matching the *name_patterns*.

- -silent

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This -silent option has no effect on any other error reporting.

Note

 You can use the -silent switch to manage the case in which an empty collection is returned. Before using the -silent switch for this purpose, refer to the set_tcl_shell_options -change_no_result_warnings_to_errors switch description for detailed usage.

Examples

The following examples demonstrate the usage of the `get_bundle_objects` command:

Example 1

```
set b1 [get_bundle_objects $b -children]
```

```
{Bus [0]} {Bus [1]}
```

```
get_bundle_objects -of_objects {Bus[0].Addr} -leaf
```

```
Bus [0].Addr.state_encoded [2]} {Bus [0].Addr.state_encoded [1]}  
{Bus [0].Addr.state_encoded [0]} {Bus [0].Addr.dt_lcp_pulse.eventbus [2]}  
{Bus [0].Addr.dt_lcp_pulse.eventbus [1]}  
{Bus [0].Addr.dt_lcp_pulse.eventbus [0]} {Bus [0].Addr.eventbus_encoded [3]}  
{Bus [0].Addr.eventbus_encoded [2]} {Bus [0].Addr.eventbus_encoded [1]}  
{Bus [0].Addr.eventbus_encoded [0]}
```

Example 2

```
typedef struct packed {  
    logic f;  
} struct_t;
```

```
typedef struct_t [1:0][1:1] array_t;  
input array_t data_in [2:0]
```

```
get_bundle_objects -of_objects [get_ports data_in[2] -bundle]
```

```
{data_in [2] [1] data_in [2] [0]}
```

```
get_bundle_objects -of_objects [get_ports data_in[2] -bundle] -leaf
```

```
{data_in [2] [1] [1].f data_in [2] [0] [1].f}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -leaf
```

```
{data_in [2] [1] [1].f data_in [2] [0] [1].f}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -children
```

```
{data_in [2] [1] [1] data_in [2] [0] [1]}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -parent
```

```
{data_in [2] data_in [2]}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -root
```

```
{data_in data_in}
```

get_capture_timing_option

Context: all contexts

Mode: all modes

Returns specific capture timing options specified with the `set_capture_timing_options` command.

Usage

```
get_capture_timing_option
  [-icl_module icl_module_name
  | -module module_name
  | -current_design
  | -current_physical_block]
  -mode_type {internal | external}
  {-capture_clock_period [-time_unit {s | ms | us | ns | ps | fs | as_is}]
  | -capture_clock_edge1_percentage
  | -capture_clock_edge2_percentage
  | -capture_clock_high_pulse_width
  | -min_capture_window_in_ssn_bus_cycles
  | -pi_setup_extra_cycles
  | -pi_hold_extra_cycles
  | -pi_force_percentage
  | -po_measure_percentage}
```

Description

The `get_capture_timing_option` command returns information about a specified capture timing setting previously configured with the `set_capture_timing_options` command.

If you specified a module with the `set_current_physical_block` command and the capture timing options for the module, the tool returns those values. If you did not specify a module, the tool traverses the design hierarchy until it finds a parent that was specified as a physical block. Otherwise, the tool uses the module inherited from the current design, and returns the default values if no options were set.

If the module has multiple instantiations and all its instances inherit from the same parent, then the tool returns the values of that parent. If the instances of module inherit from different parents (see [Figure 4-1](#)), then the tool issues the following error:

```
// Error: The specified Module 'foo' was not set as a physical block by
// 'set_current_physical_block' command. It has multiple instances that
// do not belong to the same physical block.
```

For example, [Figure 4-1](#) shows that module A was never specified as a physical block, and module B was specified as physical block. Because module A has two instances, one of them inherits from block B and the other inherits from current design TOP. This scenario will result in an error.

Figure 4-1. Design Inheritance and Module Matching

Arguments

- `-icl_module icl_module_name`
A switch and string pair that specifies the name of a valid ICL module from which to return the timing option.
- `-module module_name`
A switch and string pair that specifies the name of a module from which to return the timing option.
- `-current_design`
A switch that specifies retrieving the timing option from the current design.
- `-current_physical_block`
A switch that specifies retrieving the timing option from the current physical block. This is the default.
- `-mode_type {internal | external}`
A switch and literal pair that specifies the capture mode.
- `-capture_clock_period [-time_unit {s | ms | us | ns | ps | fs | as_is}]`
A switch and optional switch and literal that returns the capture clock period set with the `"set_capture_timing_options -capture_clock_period"` command.
The `-time_unit` switch-value pair is an optional Boolean that can be used when the command is returning a Value time property value; it is ignored otherwise. When specified or defaulted to `as_is`, the time value is returned unmodified with the unit string specified if it existed in the value of the configuration element. When specified to a value other than `as_is`, the time value is converted into a real number formatted to the specified units. The unit string is also dropped. The default unit is nanoseconds (ns).
- `-capture_clock_edge1_percentage`
A switch that returns the edge 1 capture clock percentage value set with the `"set_capture_timing_options -capture_clock_edge1_percentage"` command.

- **-capture_clock_edge2_percentage**
A switch that returns the edge 2 capture clock percentage value set with the “[set_capture_timing_options -capture_clock_edge2_percentage](#)” command.
- **-capture_clock_high_pulse_width**
A switch that returns the capture clock high pulse width value set with the “[set_capture_timing_options -capture_clock_high_pulse_width](#)” command.
- **-min_capture_window_in_ssn_bus_cycles**
A switch that returns the minimum width of the capture window in bus clock cycles set with the “[set_capture_timing_options -min_capture_window_in_ssn_bus_cycles](#)” command.
- **-pi_setup_extra_cycles**
A switch that returns the PI setup extra cycles value set with the “[set_capture_timing_options -pi_setup_extra_cycles](#)” command.
- **-pi_hold_extra_cycles**
A switch that returns the PI hold extra cycles value set with the “[set_capture_timing_options -pi_hold_extra_cycles](#)” command.
- **-pi_force_percentage**
A switch that returns the PI for percentage value set with the “[set_capture_timing_options -pi_force_percentage](#)” command.
- **-po_measure_percentage**
A switch that returns the PO measure percentage value set with the “[set_capture_timing_options -po_measure_percentage](#)” command.

Examples

The following example returns the internal capture timing options for the capture clock period for the module moduletest.

```
get_capture_timing_option -mode_type internal -capture_clock_period \  
-icl_module moduletest
```

get_cdp_test_data

Context: patterns -silicon_insight

Mode: all

Returns requested information for a specific CDP test.

Usage

```
get_cdp_test_data test_name
  { -user_pattern_file | -diagnostic_pattern_files |
    -dynamic_parameter_value dynamic_parameter_name |
    { -user_pattern_variable_list |
      -user_pattern_variable_location_data user_pattern_variable_location_data }
    [-variable_type variable_type] }
```

Arguments

- ***test_name***
A required string that specifies the CDP test to return information for.
- **-user_pattern_file**
A required switch that returns the path, relative to the CDP, for the main user (that is, gogo) pattern file for the specified CDP test.
- **-diagnostic_pattern_files**
A required switch that returns the paths, relative to the CDP, for all diagnostic pattern files for the specified CDP test.
- **-dynamic_parameter_value** *dynamic_parameter_name*
A required switch and string pair that returns the value of the dynamic parameter with the specified name.
- **-user_pattern_variable_list** [-variable_type *variable_type*]
A required switch and optional switch and literal pair that returns a list of register names in the main user pattern for the specified CDP test. By default, this returns all such registers. Restrict the list with the -variable_type switch; <*variable_type*> can be one of read, write, or any.
- **-user_pattern_variable_location_data** *user_pattern_variable_location_data* [-variable_type *variable_type*]
A required switch and string pair with an optional switch and literal pair that returns location data for specific variables or registers. By default, this returns all matching variables or registers. Restrict the list with the -variable_type switch; <*variable_type*> can be one of read, write, or any.

Examples

```
get_cdp_test_data MemoryBist_P1 -user_pattern_variable_location_data \  
run_time_prog::blockA_inst.mem1_interface_inst.GO_ID_REG
```

```
{VectorID 26 Type read Value b00000000 VarBits 0:7 RelativeCycles 20:27 Pin tdo}
```

The values in this example correspond to the following:

- **VectorID** — Location in pattern, given as *<vector_address>:<cycle_count>* for STIL and *<command ID>* for SVF.
- **Type** — “read” or “write”.
- **Value** — ‘b’ followed by the expected value in binary.
- **VarBits** — Bit range with LSB/MSB orientation. Use this with the RelativeCycles data to determine the overall order in which the pin returns the bits.
- **RelativeCycles** — Time slot offset and orientation of data on the pin.
- **Pin** — Name of the pin on which the register value appears.

For more information about these values, refer to the section “[Retargeted Symbolic Variables](#)” in the *Tessent IJTAG User’s Manual*.

[set_cdp_test_data](#)

get_cdp_test_list

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Returns a Tcl list of tests currently available in the CDP.

Usage

```
get_cdp_test_list
```

Arguments

None

Examples

The following example shows how you can use this command to return a Tcl list of the current tests within the CDP.

```
foreach test [get_cdp_test_list] {  
    execute_cdp_test $test  
}  
  
taptest membist1 membist2 logicbist1 logicbist2
```

Related Topics

[execute_cdp_test](#)

get_clock_option

Context: all contexts

Mode: setup, analysis

Prerequisites: The current design must be set.

Returns the setting of an option specified with the `add_clocks` command.

Usage

```
get_clock_option object_spec
  {-type | -off_state | -pulse_always | -period [-timeplate timeplate]
  [-time_unit {ps | ns | us | ms | s}]
  | -pulse_in_capture
  | -label
  | -reference
  | -reference_inv
  | -freq_multiplier
  | -freq_divider}
  | -dft_inject_node
  | -no_dft_connections
  [-silent] [-map_pseudo_ports]
```

Description

Returns the setting of an option specified with the `add_clocks` command.

The `get_clock_option` command returns the setting of a single option type for a single defined clock. You use the `get_clocks` command to gather the list of defined clocks.

Note

For more information about any of the following switches, refer to corresponding switch in the `add_clocks` command description.

Arguments

- *object_spec*
A required string that specifies an existing clock using the name of a port, pin, pseudo_port, label, or a collection of one port, or one pin, one pseudo_port, or one label object.
- -type
An optional switch that returns one of the following literals: `sync_source`, `async_source`, `branch`, or `generated_source`. For information about the clock types, refer to the `add_clocks` command description.

- **-off_state**
An optional switch that returns 0 or 1 for synchronous clocks, and null for asynchronous clocks.
- **-pulse_always**
An optional switch that returns a value of 1 if the clock is a pulse-always clock or 0 if it is not a pulse-always clock. A pulse-always clock is pulsed during every cycle of the pattern set.
- **-period [-timeplate *timeplate*] [-time_unit {ps | ns | us | ms | s}]**
An optional switch that returns the clock period if specified. These two options can be used with the **-period** switch:
 - **-timeplate *timeplate*** — An optional switch and string pair used to identify the timeplate for determining the period from the timeplate specified in the procedure file. This option applies to, and must be specified for, synchronous clocks. When a synchronous clock is not pulsed in the specified timeplate, the time returned is three times the period of the timeplate. The “set time scale” statement in the procedure file defines the unit the tool uses for the timeplate period if you do not specify the **-time_unit** option.
 - **-time_unit { ps | ns | us | ms | s }** — An optional switch that specifies the time unit for the period. The time unit is not part of the returned string when using the **-time_unit** switch. There is no default unit for the period. The tool returns the period of synchronous clocks in the unit of the specified timeplate and the period of asynchronous clocks in the unit specified for the period in the [add_clocks](#) command.
- **-pulse_in_capture**
An optional switch that returns a 0 or 1 to indicate whether the clock is a pulse-in-capture clock and the source is synchronous. This switch returns null when the source is asynchronous.
- **-label**
An optional switch that returns the string value of the label name. If you did not previously specify a label, the tool supplies a unique label.
- **-reference**
An optional switch that returns a collection with the object that the **-reference** option referred to when the [add_clocks](#) or [set_clock_options](#) commands was run. If the **-reference** switch was not specified, it returns an empty collection.
- **-reference_inv**
An optional switch that returns a collection with the object that the **-reference_inv** option referred to when the [add_clocks](#) or [set_clock_options](#) commands was run. If the **-reference_inv** switch was not specified, it returns an empty collection.

get_clock_option

- **-freq_multiplier**
An optional switch that returns the integer value of `freq_multiplier`, if specified; otherwise, it returns a 1.
- **-freq_divider**
An optional switch that returns the integer value of `freq_divider`, if specified; otherwise, it returns a 1.
- **-dft_inject_node**
An optional switch that returns the node object you specified with the `-dft_inject_node` option to the [add_clocks](#) or [set_clock_options](#) commands. If you did not specify an injection node with the `-dft_inject_node` switch for those commands, the tool returns a node object that is the clock node. See also the `-map_pseudo_ports` switch.
- **-no_dft_connections**
An optional switch that returns a 0 or 1 to indicate if the clock has DFT connections as specified with the `-no_dft_connections` option to the [add_clocks](#) or [set_clock_options](#) commands.
- **-silent**
An optional switch that suppresses the error message normally generated if the specified *object_spec* is not a clock, and returns a null. The `-silent` option has no effect on any other error reporting. You use this switch to determine if the *object_spec* is a clock. If the command “`get_clock_option object_spec -type -silent`” returns a null, you know *object_spec* is not a clock. When it returns a string, you know that *object_spec* is a clock and also its type.
- **-map_pseudo_ports**
An optional switch that specifies mapping pseudo ports to their associated pin or net objects. When using the `-reference` switch or the `-reference_inv` switch, and the returned reference or `reference_inv` object is a `pseudo_port`, the command returns the port or pin object on which the `pseudo_port` was created, instead of the `pseudo_port` object.

When `-map_pseudo_ports` is not specified, the tool returns the `pseudo_port` object. When the clock is not a `pseudo_port`, the switch has no effect.

If you use this switch in conjunction with the `-dft_inject_node` switch, the tool returns the related hierarchical pin for the `pseudo_port`.

Examples

Example 1

The following example adds two clocks to the clock list, reports on the clocks, and then shows several ways of using the `get_clock_option` command:

```
SETUP> add_clocks 0 I3 -pulse_always -label clock3
```

```
SETUP> add_clocks 1 I4 -period 50 ns -freq_multiplier 2 -label clock4
```

SETUP> report_clocks

User-defined Clocks (2):

=====

Sync and Async Source Clocks

=====

Name	Label	Off State	Constraints	Internal	Period	Freq. Multiplication
'I3'	clock3	0	Pulse always	No		
'I4'	clock4	-	Asynchronous	No	50.00ns	2

SETUP> get_clock_option I3 -label clock

clock3

SETUP> get_clock_option I4 -freq_multiplier

2

SETUP> get_clock_option I4 -period -time_unit ps

50000.0

SETUP> get_clock_option I3 -pulse_in_capture

0

SETUP> get_clock_option I4 -freq_divider

1

SETUP> get_clock_option I3 -reference

{}

Example 2

This example demonstrates the use of the `-map_pseudo_port` switch. It also shows the effect when you do not use the switch.

```
add_clocks {/pll1_i1/tdr1_IPLL1/U15/Y} -pseudo_port my_cut_pi -reference tck
```

```
// Note: Primary input 'my_cut_pi' is added at pin '/pll1_i1/tdr1_IPLL1/U15/Y'.
```

```
add_clocks {/pll1_i1/tdr1_IPLL1/U16/Y} -reference my_cut_pi
```

```
get_clock_option {/pll1_i1/tdr1_IPLL1/U16/Y} -reference -map_pseudo_ports
```

```
{pll1_i1/tdr1_IPLL1/U15/Y}
```

```
get_clock_option {/pll1_i1/tdr1_IPLL1/U16/Y} -reference
```

```
{my_cut_pi}
```

[delete_clocks](#)

[report_clocks](#)

[set_clock_options](#)

get_clocks

Context: all contexts

Mode: setup, analysis

Prerequisites: The current design must be set.

Returns a collection of user clocks based on filters you specify.

Usage

```
get_clocks [name_patterns [-match {all | pin_or_port_name | label_name}] [-regexp] [-nocase]]  
          [-type {sync_source | async_source | generated | branch}] [-silent] [-map_pseudo_ports]
```

Description

Returns a collection of user clocks based on filters you specify.

The `get_clocks` command returns a collection of all clock objects in your design created with `add_clocks` or a subset based on filters you specify.

Arguments

- *name_patterns*
An optional string or Tcl list of strings that specifies one or more patterns to filter the list of returned list of clock objects.
- `-match {all | pin_or_port_name | label_name}`
An optional switch and literal pair that specifies to match the *name_patterns* with pin or port names, label names, or both (All). By default, the command matches all.
- `-regexp`
An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a real regular expression instead of as a simple wildcard pattern.
- `-nocase`
An optional switch that directs the tool to perform case-insensitive pattern matching when looking for clocks matching the *name_patterns*.
- `-type {sync_source | async_source | generated | branch}`
An optional switch and literal pair that specifies the type of clock to return. By default, the command returns all types of clocks. For information about the clock types, refer to the “Usage” section of the [add_clocks](#) command description.
- `-silent`
An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options` [-change_no_result_warnings_to_errors](#) switch description for detailed usage.

- `-map_pseudo_ports`

An optional switch that specifies mapping pseudo ports to their associated pins or net objects. When the clock is a pseudo_port and this switch is used, the command returns the port or pin object on which the pseudo_port was created, instead of the pseudo_port object.

When `-map_pseudo_ports` is not specified, the tool returns the pseudo_port object.

This switch has no effect when the clock is not a pseudo_port.

Examples**Example 1**

The following example creates two `sync_source` clocks and then shows different ways to use the `get_clocks` command:

```

SETUP> add_clocks I1 -pulse_always -label clock1
SETUP> add_clocks I2 -pulse_in_capture -label clock2
SETUP> get_clocks
{I1 I2}

SETUP> get_clocks I* -match label_name
// Error: 'I*' is not a clock.
{}

SETUP> get_clocks * -match label_name
{I1 I2}

SETUP> get_clocks clock* -match label_name
{I1 I2}

SETUP> get_clocks I* -type sync_source
{I2 I1}

SETUP> get_clocks I* -type async_source
{}

SETUP> get_clocks c*2 -match label_name
{I2}

```

Example 2

This example creates a `pseudo_port` and then demonstrates using the `-map_pseudo_port` switch to return the pin information for the `pseudo_port`. It also shows the result when the switch is not used.

```
add_clocks {/pll1_I1/tdr1_IPLL1/U15/Y} -pseudo_port my_cut_pi -reference tck
```

```
// Note: Primary input 'my_cut_pi' is added at pin '/pll1_I1/tdr1_IPLL1/  
U15/Y'
```

```
get_clocks my_cut_pi -map_pseudo_port
```

```
{pll1_I1/tdr1_IPLL1/U15/Y}
```

```
get_clocks my_cut_pi
```

```
{my_cut_pi}
```

get_common_parent_instance

Context: all contexts

Mode: all modes

Returns the common ancestor of all instances, pins, or nets found in *object_spec*.

Usage

get_common_parent_instance *object_spec*

Description

Returns the common ancestor of all instances, pins, or nets found in *object_spec*.

You can use this command during dft insertion when you want to place a driving gate at the common ancestor of all its fanouts.

Arguments

- *object_spec*

A required value that specifies a Tcl list of one or more object names or a collection of one or more objects to find their common ancestor.

Examples

The following example finds the common ancestor of all pins having the attribute myAtt set to true. The name of the returned instance object is then used to instantiate a driver cell. Quotation marks enclose the concatenation of `${parent_name}` and `/myGate` to make sure that the command preserves any white spaces that may exist in `${parent_name}` (when it contains escaped identifiers).

```
set parent [get_common_parent_instance [get_pins -filter myAtt]]
set parent_name [get_single_name $parent]
set driver [create_instance "${parent_name}/myGate" -of_module MyMod]
```

get_config_elements

Context: unspecified, dft, patterns

Mode: all modes

Returns a collection of configuration elements or a count of configuration elements when the -count option is used.

Usage

```
get_config_elements [name_patterns] [-hierarchical] [-in_wrappers wrapper_object_spec]  
    [-partition partition] [-count] [-type type] [-filter filter]  
    [-regexp] [-nocase] [-silent]
```

Description

Returns a collection of configuration elements or a count of configuration elements when the -count option is used.

When no *name_patterns* is specified, then all elements are returned unless the -in_wrappers option is specified, in which case only the elements below the specified wrappers are returned. When using one or many *name_patterns*, only the elements whose name matches at least one of the *name_patterns* are returned.

Arguments

- *name_patterns*

An optional string that specifies one name pattern or a Tcl list of name patterns to search. The name patterns are automatically decomposed into a series of anchored leaf name patterns using the / as a separator. The name identifiers are always matches ignoring case. The ids found inside the parentheses are matched taking into account case unless the -nocase option is used. The comma has special meaning inside the parentheses and is used to split the patterns and match each id independently. A leaf pattern that does not include a set of parentheses matches all elements matching the leaf name irrespective of whether it has ids or not. See the examples below for a complete illustration of the matching method.

When the -in_wrappers option is specified, the *name_patterns* are described relative to the specified wrappers, When the -hierarchical option is specified, the *name_patterns* are matched recursively against all elements below the specified wrappers.

- -hierarchical

An optional string that specifies that the *name_patterns* are matched recursively against all elements below the specified wrappers.

You should use this option with care and avoid using it inside scripts that are intended to be run continually throughout a development cycle. For example, you would not normally use the “get_pins clka -hierarchical” command to find “u1/u2/clka” in a script that is meant to run on a design as it evolves. For the same reason, you should not use the -hierarchical

option in a configuration editing script. Although a *leaf_name* may be unique now, there is no guarantee that it continues to remain unique in the future.

- **-in_wrappers** *wrapper_object_spec*

An option and value pair that specifies that the configuration elements are to be searched inside specific wrappers. When the **-in_wrappers** option is specified, the *name_patterns* are searched relative to the specified wrappers. The *wrapper_object_spec* can be the complete names of wrappers relative to the root of the partition or a collection containing one or many wrapper elements as returned by [get_config_elements](#) or “[get_config_value](#) -object”. When specifying the names of the wrapper, you can use the **-partition** option to specify in which partition the wrappers exist.

- **-partition** *partition_name*

An optional switch and value pair that specifies the partition from which the configuration element is to be obtained. When using the **-in_wrappers** option, the **-partition** option can only be specified if the *wrapper_object_spec* is the name of a wrapper. When the *wrapper_object_spec* is a collection containing wrapper objects, the **-partition** option cannot be specified because a specific partition is already associated to the configuration objects. All configuration data you normally interact with is in the default partition, so you typically never need to specify the **-partition** option.

The tool defines two partitions:

- **default partition** — a partition that stores all user specifications; contains the definition of [DftSpecification](#), and [DefaultsSpecification/DftSpecification](#) wrappers
- **tcd partition** — a read-only partition in which the [read_core_descriptions](#) command stores the data contained inside the *Core(module_name)* wrapper

- **-count**

An optional Boolean option that specifies to return the number of elements matched as opposed to the elements themselves.

- **-type** *wrapper* | *data_wrapper* | *csv_wrapper* | *property*

An optional switch and value pair that specifies to limit the search to a specific configuration element type. When the **-type** option is omitted, all types are considered in the matching.

- **-filter** *attribute_equation*

An optional switch and string pair that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the configuration element types being filtered. See section “[Attribute Filtering Equation Syntax](#)” for more details on filtering attribute equation format. The `=~` and `!~` matching operators use simple wildcard matching versus Posix extended regular expression based on the presence of the **-regex** option.

- **-regexp**
An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a regular expression instead of as a simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” for a description of the regular expression syntax.
- **-nocase**
An optional switch that directs the tool to perform case-insensitive pattern matching when matching the **Ids** of wrapper and repeatable properties. The wrapper and property names are always matched ignoring casing.
- **-silent**
An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This **-silent** option has no effect on any other error reporting.

Note

You can use the **-silent** switch to manage the case in which an empty collection is returned. Before using the **-silent** switch for this purpose, refer to the “[set_tcl_shell_options](#) -” switch description for detailed usage.

Examples

The following example operates on the following configuration data:

```
tmp(1) {
  ABC (Def, 2) {
    prop1 : 1;
    Prop2 : 2;
  }
  abc (def, 1) {
  }
  abcdef {
  }
}
```

Case 1

This matches all wrappers with a leaf name starting with **abc** inside wrapper **tmp(1)** independent of whether it has an id. The matching is case-insensitive because only the id matching is case-sensitive.

get_config_element abc -in tmp(1)

```
{/tmp(1)/ABC (Def, 2) /tmp(1)/abc (def, 1)}
```

Case 2

This matches the wrappers with the first id equal to Def. Notice that it does not match abc(def,1) as ids are matched considering casing unless the -nocase option is used.

```
get_config_elements *(Def,*) -in tmp(1)
```

```
{/tmp(1)/ABC(DeF,2)}
```

```
get_config_elements *(Def,*) -in tmp(1) -nocase
```

```
{/tmp(1)/ABC(DeF,2) /tmp(1)/abc(def,1)}
```

Case 3

This matches elements below the top-level wrapper starting with a*.

```
get_config_element */a*
```

```
{/tmp(1)/ABC(DeF,2) /tmp(1)/abc(def,1) /tmp(1)/abcdeF}
```

Case 4

This matches elements below the top-level wrapper starting with a* and having two ids.

```
get_config_element */a*(*,*)
```

```
{/tmp(1)/ABC(DeF,2) /tmp(1)/abc(def,1)}
```

Case 5

This matches elements starting with 'p' anywhere inside tmp(1).

```
get_config_element p* -in tmp(1) -hierarchical
```

```
{/tmp(1)/ABC(DeF,2)/prop1 /tmp(1)/ABC(DeF,2)/Prop2}
```

Case 6

This matches elements starting with 'p' anywhere inside tmp(1) and returns the amount of elements that matched instead of the elements themselves.

```
get_config_element p* -in tmp(1) -hierarchical -count 2
```

Related Topics

[add_config_element](#)

[get_config_value](#)

get_config_messages

Context: unspecified, dft, patterns

Mode: all modes

Returns a list of message strings attached to a configuration element.

Usage

```
get_config_messages config_object_spec
    [-string | {-objects [-hierarchical]}]
    [-all | {[-error] [-warning] [-info]}
```

Description

Returns a list of message strings attached to a configuration element.

By default, all message types are returned unless you specify at least one of the -error, -warning, or -info options. If you specify the -objects option, the command returns the configuration element if it has messages of the specified type.

Arguments

- *config_object_spec*
A required value that specifies the name of a configuration element or a collection containing one configuration element.
- -string
An optional Boolean option that specifies that the command is to return the messages formatted into strings exactly as they are shown with the [report_config_messages](#) command. The entries start with E#), W#) and I#) based on the type of the message and # is incremented from 0 independently for each type.
The use of -string is mutually exclusive with the -objects option, When either is specified, -string is assumed.
- -objects
An optional Boolean option that specifies to return a collection of configuration elements having at least one message of the specified type.
- -hierarchical
An optional Boolean option that specifies that the config_object_spec is a wrapper and that the command should return all elements below the specified wrapper having at least one configuration message for the specified types. This option is only permitted in combination with the -objects option

- **-all**
An optional Boolean option that specifies that all messages types are to be returned. The use of the **-all** option is mutually exclusive with the specification of the **-error**, **-warning** and **-info** options. When none of the four options is specified, **-all** is assumed.
- **-error**
An optional Boolean option that specifies that the messages returned are of type error. The use of the **-error** option is mutually exclusive to the specification of the **-all**, **-warning**, and **-info** options. When none of the **-error**, **-warning** and **-info** options is specified, **-all** is assumed.
- **-warning**
An optional Boolean option that specifies that the messages returned are of type warning. The use of the **-error** option is mutually exclusive with the specification of the **-all**, **-warning**, and **-info** options. When none of the **-error**, **-warning**, and **-info** options is specified, **-all** is assumed.
- **-info**
An optional Boolean option that specifies that the messages returned are of type info. The use of the **-error** option is mutually exclusive with the specification of the **-all**, **-warning**, and **-info** options. When none of the **-error**, **-warning** and **-info** options is specified, **-all** is assumed.

Examples

The following example adds an error message to the property `rtl_extension` inside `DftSpecification(mydesign,rtl)`. The `get_config_messages` is then used to get the message string list on the property. The command “`get_config_messages -objects -hierarchical`” is also used to get a collection of all elements below `DftSpecification(mydesign,rtl)` with an error message.

```
set_context dft -rtl
```

```
set spec [add_config_el DftSpecification(mydesign,rtl)]
```

```
add_config_message "this is an error string \non two lines" \  
  -config_element [get_config_el rtl_extension -in $spec] \  
  -error -display
```

```
// Error: /DftSpecification(mydesign,rtl)/rtl_extension  
//      this is an error string  
//      on two lines
```

```
get_config_messages [get_config_el rtl_extension -in $spec]
```

```
E0) this is an error string  
    on two lines
```

```
get_config_messages $spec -objects -hier {/DftSpecification(mydesign,rtl)/rtl_extension}
```

get_config_selected_nodes

Context: dft, patterns

Mode: all modes

Returns a collection containing the configuration elements corresponding to the tree nodes currently selected in the Configuration Data Visualizer.

Usage

```
get_config_selected_nodes
```

Description

Returns a collection containing the configuration elements corresponding to the tree nodes currently selected in the Configuration Data Visualizer.

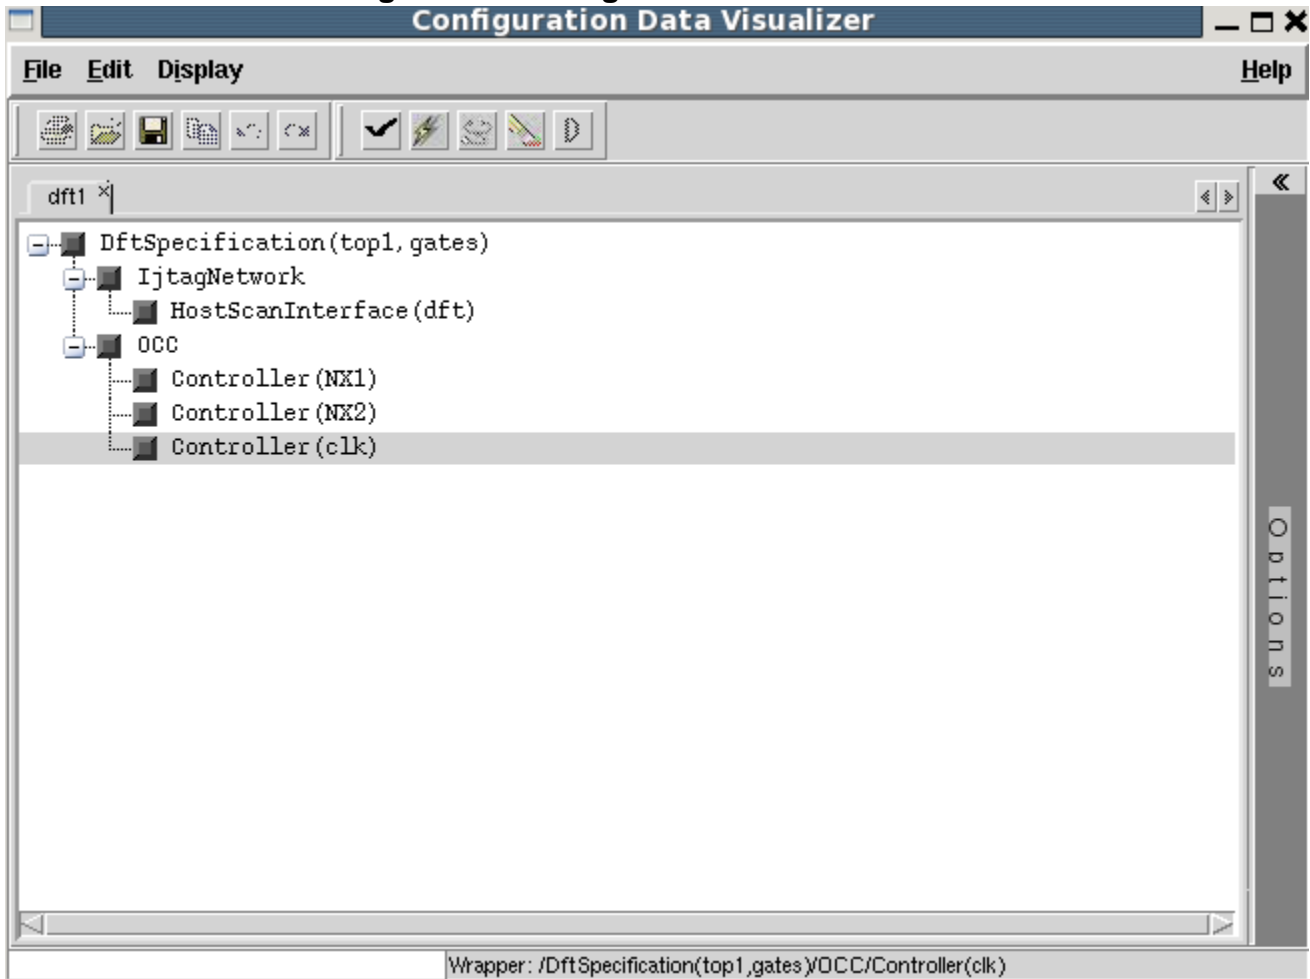

Arguments

None

Examples

The following example shows the result of the command when a node (Controller(clk)) is selected in the Configuration Data Visualizer as shown in [Figure 4-2](#). You can select more than one element by pressing the Shift or Control key while selecting the second element.

Figure 4-2. Configuration Data Visualizer

get_config_select_node

```
{/DftSpecification(top1,gates)/OCC/Controller(clk)}
```

get_config_value

Context: unspecified, all contexts

Mode: all modes

Returns a value associated with a configuration element based on the specified option.

Usage

```
get_config_value config_object [-in_wrapper wrapper_object_spec]  
  [-time_unit {s | ms | us | ns | ps | fs | as | as_is}]  
  [-number_format {int | bin | hex | as_is}]  
  [-reference_name | -reference_object | -parent_name | -parent_object | -type | -name |  
  -id id | -value_id value_id | -value_as_list | -is_specified | -has_inherited_default |  
  -id_count | -value_count | -exists | -root_name | -root_object | -leaf_name | -base_name |  
  -meta_name | -meta_object | -meta_id | -partition_name]  
  [-default_value | -comment]  
  [-tolower | -toupper]  
  [-file_name]  
  [-object]  
  [-partition partition]  
  [-silent]
```

Description

Returns a well-formatted Tcl list when the property permits a comma-separated list of values. See the [Value ID](#) description in the metadata section that shows that terminating the ID with an asterisk "*" indicates that the value accepts a comma-separated list of values.

[Figure 4-3](#) below illustrates some of those values.

Figure 4-3. Various Components of a Configuration Element

Arguments

- **config_object**

A required value that specifies the name of a configuration element or a collection containing one configuration element. When **config_object** is a collection, the `-in_wrapper` and `-partition` options cannot be used because the object contains all of the information about the configuration element. In order to use the `-in_wrapper` option, the **config_object** value must be a name and the name must be relative to the specified wrapper element. You

can use a positional id for any level of hierarchy. You can also replace the id of a leaf name by the position. For example, the path “tmp(1)/<0>/wrp<1>” means “tmp(1)/wrp(abc)/wrp(def)” if “wrp(abc)” is the first element found inside “tmp(1)”, and “wrp(def)” is the second instance of a wrapper with a base name of “wrp” inside “tmp(1)/wrp(abc)”.

- **-in_wrapper** *wrapper_object_spec*

An optional switch and value pair that is used to specify the parent wrapper in which the configuration element exists. The *wrapper_object_spec* value is the name of a wrapper or a collection containing a wrapper element. The name in *config_object* is relative to the specified parent wrapper.

- **-time_unit** s | ms | us | ns | ps | fs | as | as_is

An optional Boolean option that can be used when the command is returning a **Value** time property value; it is ignored otherwise. When specified or defaulted to *as_is*, the time value is returned unmodified with the unit string specified if it existed in the value of the configuration element. When specified to a value other than *as_is*, the time value is converted into a real number formatted to the specified units. The unit string is also dropped.

- **-number_format** int | bin | hex | as_is

An option and value pair that can be used when the command is returning a **Value** binary property or hexadecimal value. It is ignored otherwise. When specified or defaulted to *as_is*, the value is returned unmodified with the format if it existed in the value of the configuration element. When specified to a value other than *as_is*, the binary or hexadecimal value is converted into the specified format.

- **-reference_name**

An optional Boolean option that specifies that the data requested is the name of the referenced metadata element. If the metadata is not a **Wrapper** reference property, this returns a null string.

- **-reference_object**

An optional Boolean option that specifies that the data requested is a collection containing the referenced metadata element. If the metadata is not a **Wrapper** reference property, this returns an empty collection.

- **-parent_name**

An optional Boolean option that specifies that the data requested is the name of the wrapper in which the configuration element exists. If the element is a root wrapper, the string / is returned.

- **-parent_object**

An optional Boolean option that specifies that the data requested is a collection containing the wrapper in which the configuration element exists. If the element is a root wrapper inside a given partition, a collection containing the partition in which the root wrapper exists is returned.

- **-type**
An optional Boolean option that specifies that the data requested is the type of the configuration element. The type is either `wrapper`, `data_wrapper`, `csv_wrapper`, `property`, `repeatable_property`, `data_element`, or `csv_element`. [Table 4-3](#) explains each type in more details.

Table 4-3. Types of Configuration Elements

Type	Description
wrapper	Type returned for a Wrapper used to groups other wrappers and properties.
data_wrapper	Type returned for a DataWrapper used to group <code>data_row</code> elements.
csv_wrapper	Type returned for a CsvWrapper used to group <code>csv_row</code> elements.
property	Type returned for a Property .
repeatable_property	Type returned for a RepeatableProperty property.
data_row	Type returned for elements found inside a DataWrapper .
csv_row	Type returned for elements found inside a CsvWrapper .

- **-name**
An optional Boolean option that specifies that the data requested is the name of the configuration element. As shown in [Figure 4-3](#) on page 884, the name is the complete name including all hierarchical levels. If, at any level in the hierarchy, the `leaf_name` is not unique, the `leaf_name` is replaced by a positional index so as to have a unique name for each element. For example, if there are two instances of the same wrapper called “port(abc)” inside the same parent wrapper called “ports”, the name would be reported as “/Ports/Port(<2>)” assuming it is the third element inside “/ports”.
- **-id position | id_name | all**
An optional switch and value pair that specifies that the data requested is the id of a wrapper or of a repeatable property. When using `-id all`, the command returns a well-formatted Tcl list unless the configuration element has metadata and there is only one non repeatable Id declared for it. In this case the value is returned as a Tcl string, which is the case for most wrappers and repeatable properties you introspect.

When you have configuration elements with more than one Id, you can query one id at a time using either its position or when it has metadata, the id of the ID wrapper that declares the id. A position is represented with an integer surrounded by `<>`. For example, `<0>` is the first value, `<1>` is the second, and so on. In such a case, the id is returned as a string except when using the id of a repeatable id in which case a well-formatted Tcl list is returned.
- **-value_as_list**
An optional switch that specifies that the command always return a list, even for properties that can hold a single value. Using this switch, it is possible to process a collection of mixed properties: where some can hold a single value (when the `value_id` of the metadata of the

property does not end with a wildcard character, such as `Value(port_pin_name)`), or many values (when the `value_id` in metadata ends with a wildcard, such as `Value(port_pin_name*)`).

For example, consider the following properties from the `EdtChannelsIn` wrapper of the `DftSpecification`. The `pipeline_clock` property is specified with `Value(port_pin_name)` in the metadata, and the property `port_pin_name` is specified with `Value(port_pin_name*)`:

```
EdtChannelsIn {
  pipeline_clock : "/modInst/\subMod[0] /clk";
  port_pin_name  : "\port[1] [0]";
}
```

The command

```
> get_config_value pipeline_clock -in_wrapper $edtChannelInObj
```

returns the value of a Tcl string `/modInst/\subMod[0] /clk`, which Tcl interprets as a list of two elements: `/modInst/\subMod[0]` and `clk`, if iterated as a list.

By comparison, the command:

```
> get_config_value port_pin_name -in_wrapper $edtChannelInObj
```

returns a Tcl list of one element, `{\port[1] [0]}`, because the `port_in_name` property can be multi-valued.

Using the `-value_as_list` switch ensures that `get_config_value` always returns a list, even for the `pipeline_clock` property:

```
> set portPinPathList [get_config_value pipeline_clock \
  -value_as_list -in_wrapper $edtChannelInObj]
{/modInst/\subMod[0] /clk}
> set portPinPathList [get_config_value port_pin_name \
  -value_as_list -in_wrapper $edtChannelInObj]
{\port[1] [0]}
```

This way it is possible to iterate over the two properties in a single loop and process the right number of values for each, because they are now valid Tcl lists.

- `-value_id position | value_name | all`

An optional switch and value pair that specifies that the data requested is the value of a property, repeatable property, or of a row inside a Data or CSV wrapper. If none of the options listed between `-value_count` and `-reference_object` inclusively are specified, the tool uses “`-value_id all`”.

When using “`-value_id all`”, the command returns a well-formatted Tcl list unless the configuration element has metadata and there is only one non-repeatable value declared for it. In this case, the value is returned as a Tcl string, which is the case for most properties you introspect.

When you have configuration elements with more than one elements, you can query one value at a time using either its position or, if it has metadata, the *id* of the `Value` wrapper that declares the value. A position is represented with an integer surrounded by `<>`. For example,

<0> is the first value, <1> is the second, and so on. In such a case, the value is returned as a string except when using the id of a repeatable [Value](#) in which case a well-formatted Tcl list is returned.

- **-is_specified**

An optional Boolean option that specifies that the data requested is a Boolean value that is 1 when the configuration element is specified and 0 when it is not. Remember that singular wrappers and properties exist as soon as their parent wrapper exists and regardless of whether the singular wrapper or property is specified. The parent wrapper must exist before you can query if one of its element is specified. Unspecified elements are not included in the output file when using the [write_config_data](#) or the [report_config_data](#) commands unless the `-show_unspecified` option is used.

- **-has_inherited_default**

An optional Boolean option that specifies that the default is inherited. It returns true when the property is declared with the `ReferenceWithInheritedDefault` property. For more information on the `ReferenceWithInheritedDefault` property, see “[Wrapper](#)” on page 4436.

- **-id_count**

An optional Boolean option that specifies that the data requested is the number of ids specified for the wrapper of repeatable property. A value of 0 is returned for configuration objects that do not have ids like a wrapper declared without any `Id` wrapper or a property.

- **-value_count**

An optional Boolean option that specifies that the data requested is the number of values specified for the property, the `Data` or `CSV` wrapper row. A value of 0 is returned for configuration objects that do not have values like a wrapper. Implicit Boolean properties still report one value because the true or false value is implicit but still present.

- **-exists**

An optional Boolean option that specifies that the data requested is a Boolean value that is 1 when the configuration element exists and 0 when it does not. Remember that singular wrappers and properties exist as soon as their parent wrapper exists and whether the singular wrapper or property is specified or not. You use the `-is_specified` option to know if such elements are specified or not.

- **-root_name**

An optional Boolean option that specifies that the data requested is the name of the root wrapper in which the configuration element exists. If the element is a root wrapper, its name is returned.

- **-root_object**

An optional Boolean option that specifies that the data requested is a collection containing a root wrapper in which the configuration element exists. If the element is a root wrapper, it is returned in the collection.

- **-leaf_name**

An optional Boolean option that specifies that the data requested is the leaf name of the configuration element. As shown in [Figure 4-3](#) on page 884, the leaf name is the last level of hierarchy including the `base_name` and the `ids` when they exist.
- **-base_name**

An optional Boolean option that specifies that the data requested is the base name of the configuration element. As shown in [Figure 4-3](#) on page 884, the base name is the last level of hierarchy excluding the `ids` when they exist.
- **-meta_name**

An optional Boolean option that specifies that the data requested is the name of the [Wrapper](#) wrapper used to define the configuration element. The name is constructed assuming the metadata data was declared with no [Wrapper](#) reference property to shared declaration. The `-reference_name` option is used to get the name of the element referenced.
- **-meta_object**

An optional Boolean option that specifies that the data requested is a collection containing the [Wrapper](#) wrapper used to define the configuration element. The object is the metadata data element as if it was declared with no [Wrapper](#) reference property to shared object. The `reference_object` option is used to get the referenced object.
- **-meta_id**

An optional Boolean option that specifies that the data requested is a unique integer corresponding to the [Wrapper](#) wrapper used to define the configuration element. The `meta_id` of an element declared with the [Wrapper](#) reference property is the `meta_id` of the referenced element.
- **-partition_name**

An optional Boolean option that specifies that the data requested is the name of the partition in which the configuration element exists. [Table 4-4](#) shows the returned value based on which partition the configuration element exists in.
- **-comment**

An optional Boolean option that specifies that the comment associated with the configuration element is to be returned as a string.
- **-default_value**

An optional switch that specifies that the data requested is the default value of a property. The command returns a well-formatted Tcl list unless the configuration element has metadata and there is only one non-repeatable value declared for it. In this case, the command returns the `default_value` as a Tcl string, which is the case for most properties you introspect.

You can use the `-value_id` option in combination with the `-default_value` to obtain the default value of a specific value. When requesting the default value of a single value, the return value is always a well-formatted Tcl string.

get_config_value

- **-tolower**
An optional Boolean option that can be used when the command is returning a string. It is ignored otherwise. All upper case letters are converted to lower case.
- **-toupper**
An optional Boolean option that can be used when the command is returning a string. It is ignored otherwise. All lower case letters are converted to upper case.
- **-file_name**
An optional Boolean option that specifies that the data requested is the filename from which the configuration element was read. It returns null if the configuration element was not read from a file using [read_config_data](#) but instead it was created in memory using [add_config_element](#). The *file_name* value is updated to point to the output filename as soon as it is written out using the [write_config_data](#) command.
- **-object**
An optional Boolean option that specifies that the data requested is a collection containing the configuration element just like [add_config_element](#) returns when adding an element.
- **-partition *partition_name***
An optional switch and value pair that is used to specify the partition in which the configuration element exists. When the option is unspecified, the default partition is used, which is where all specifications ([DftSpecification](#) and [DefaultsSpecification/DftSpecification](#)) are located. You can access the Core wrappers comprising the Tessent Core Description (TCD) file syntax in the tcd partition. Using the partition names meta: and meta:tcd enables you to access the metadata configuration elements that define the default and tcd partitions. The table below summarizes the available partition names.

Table 4-4. Available Partitions for Introspection

Partition name	Configuration data contained
	When the <code>-partition</code> option is unspecified, the tool accesses the default partition, which is where the DftSpecification and DefaultsSpecification/DftSpecification configuration data is located.
tcd	When the <code>-partition</code> option is specified with the tcd value, the Core wrappers comprising the Tessent Core Description file syntax is accessed.
meta	When the <code>-partition</code> option is specified with the meta value, the metadata configuration data defining the permitted syntax of the DftSpecification and DefaultsSpecification/DftSpecification is accessed.
meta:tcd	When the <code>-partition</code> option is specified with the meta:tcd value, the metadata configuration data defining the permitted syntax of the Core wrappers is accessed.

- -silent

An optional argument that specifies to ignore objects that do not exist and not to generate error messages.

Examples

This example shows usage of the [get_config_value](#) command with a wide variety of its options exercised. You can see the syntax of the configuration data at the top and the specific configuration data being introspected just after. At the bottom of the example, you can see the metadata defining the syntax.

```
set_context dft -rtl
```

```
report_config_syntax SingularWrapper
```

```
SingularWrapper {  
  WrapperWithRepeatableId(<name*>) {  
    WrapperWithRepeatableId(<name*>) {  
      // Same as /SingularWrapper/WrapperWithRepeatableId  
    }  
    time_property      : <time>          ; // default: 3.5ns  
    integer_property   : <integer>       ; // default: 3  
    binary_property    : <binary>        ; // default: 3'b0  
    string_property    : <string>, ... ;  
    CsvWrapper(<module_name>,<design_id>) {  
      <value>, ...;  
    }  
    DataWrapper_with_no_value {  
      <port> ; // repeatable  
    }  
    DataWrapper_value {  
      <port> : <period> ; // repeatable  
    }  
  }  
}
```

```
read_config_data ./data/cfg
```

```
report_config_data SingularWrapper
```

```
SingularWrapper {
  WrapperWithRepeatableId(a,b c) {
    WrapperWithRepeatableId(abc) {
      time_property : 4.5ns;
      integer_property : 6;
      binary_property : 4'b110;
      string_property : this is a string;
      CsvWrapper(mods,id1) {
        a;
        b, c;
        d, e f, g;
      }
    }
    DataWrapper_with_no_value {
      a string ;
      1;
    }
    DataWrapper_value {
      clka : 4ns;
      clkb : 6.7ms;
      clkc : 4;
    }
  }
}
```

set wrp [get_config_el WrapperWithRepeatableId(abc) -hier]

Case 1:

Get the value of a property where the type is time:

```
> puts [get_config_value time_property -in $wrp]
4.5ns
```

Case 2:

Get the time value in milliseconds with units removed:

```
> puts [get_config_value time_property -in $wrp -time_unit ms]
4.5e-06
```

Case 3:

Get the time value in nanoseconds with units removed:

```
> puts [get_config_value time_property -in $wrp -time_unit ns]
4.5
```

Case 4:

Get the value of a property where the type is integer:

```
> puts [get_config_value integer_property -in $wrp]
6
```

Case 5:

Get the value of a property where the type is binary:

```
> puts [get_config_value binary_property -in $wrp]
4'b110
```

Case 6:

Get the value of a property with a binary value converted in hexadecimal:

```
> puts [get_config_value binary_property -in $wrp -number_format hex]
4'h6
```

Case 7:

Get the value of a property with a binary value converted to integer:

```
> puts [get_config_value binary_property -in $wrp -number_format int]
6
```

Case 8:

Get the value of a property where the type is string:

```
> puts [get_config_value string_property -in $wrp]
this is a string
```

Case 9:

Get the leaf_name of a wrapper:

```
> puts [get_config_value $wrp -leaf_name]
WrapperWithRepeatableId(abc)
```

Case 10:

Get the base_name of a wrapper:

```
> puts [get_config_value $wrp -base_name]
WrapperWithRepeatableId
```

Case 11:

Get a csv wrapper object and return the number of rows in csv wrapper:

```
> set csv [get_config_value CsvWrapper(moda,id1) -in $wrp -object]
> puts [get_config_element -in $csv -count]
3
```

Case 12:

Get the values of CSV rows:

```
> puts [get_config_value CsvWrapper(mod_a,id1)/<0> -in $wrp]
a
> puts [get_config_value CsvWrapper(mod_a,id1)/<1> -in $wrp]
b c
> puts [get_config_value CsvWrapper(mod_a,id1)/<2> -in $wrp]
d {e f} g
```

Case 13:

Get the number of values in a row:

```
> puts [get_config_value CsvWrapper(mod_a,id1)/<2> -in $wrp -value_count]
3
```

Case 14:

Get specific value of a CSV row:

```
> puts [get_config_value CsvWrapper(mod_a,id1)/<2> -in $wrp -value_id <1>]
e f
```

Above is equivalent to

```
> puts [lindex [get_config_value CsvWrapper(mod_a,id1)/<2> -in $wrp] 1]
e f
```

Case 15:

Get the number of the id for a wrapper element:

```
> puts [get_config_value -id_count \
        SingularWrapper/WrapperWithRepeatableId<0>]
2
```

Case 16:

Get the leaf_name of a wrapper element:

```
> puts [get_config_value -leaf_name $wrp]
WrapperWithRepeatableId(abc)
```

Case 17:

Get the name of a wrapper element:

```
> puts [get_config_value $wrp]
SingularWrapper/WrapperWithRepeatableId(abc)
```

Case 18:

Get the base_name of a wrapper element:

```
> puts [get_config_value -base_name $wrp]
WrapperWithRepeatableId
```

Case 19:

Get the `parent_name` of a wrapper element:

```
> puts [get_config_value -parent_name $wrp]
/SingularWrapper/WrapperWithRepeatableId(a,b c)
```

Case 20:

Get the `parent_object` of a wrapper element:

```
> puts [get_single_name [get_config_value -parent_object $wrp]]
/SingularWrapper/WrapperWithRepeatableId(a,b c)
```

Case 21:

Get the `root_name` of a wrapper element:

```
> puts [get_config_value -root_name $wrp]
/SingularWrapper
```

Case 22:

Get the `root_object` of a wrapper element:

```
> puts [get_single_name [get_config_value -root_object $wrp]]
/SingularWrapper
```

Case 23:

Get the `file_name` of a wrapper element:

```
> puts [get_config_value -file_name $wrp]
/home/abc/data/ex.cfg
```

Case 24:

Gets the `meta_name` of a wrapper element:

```
> puts [get_config_value -meta_name $wrp]
/Wrapper(SingularWrapper)/Wrapper(WrapperWithRepeatableId)
```

Case 25:

Gets the `ref_name` of a metadata element. Returns null when the element is not referencing another one:

```
> puts [get_conf_value \
  SingularWrapper/WrapperWithRepeatableId/WrapperWithRepeatableId \
  -part meta -ref_name]
/Wrapper(SingularWrapper)/Wrapper(WrapperWithRepeatableId)
> puts [get_conf_value SingularWrapper/WrapperWithRepeatableId \
  -part meta -ref_name]
```

get_config_value

Case 26:

Uses `-tolower` and `-toupper` options to convert the returned string in lower case or upper case:

```
> puts [get_config_value -base_name $wrp]
WrapperWithRepeatableId
> puts [get_config_value -base_name $wrp -toupper]
WRAPPERWITHREPEATABLEID
> puts [get_config_value -base_name $wrp -tolower]
wrapperwithrepeatableid
```

Case 27:

Reports the metadata that defines the syntax being introspected:

```
report_config_data SingularWrapper -partition meta
```

```

Wrapper(SingularWrapper) {
  Repeatable : single;
  Wrapper(WrapperWithRepeatableId) {
    id(name*) {
      type : string;
    }
  }
  Reference = /SingularWrapper/WrapperWithRepeatableId;
  Property(time_property) {
    Value(time) {
      type : time;
      DefaultValue : 3.5ns;
    }
  }
  Property(integer_property) {
    Value(integer) {
      type : int;
      DefaultValue : 3;
    }
  }
  Property(binary_property) {
    Value(binary) {
      type : binary;
      DefaultValue : 3'b0;
    }
  }
  Property(string_property) {
    Value(string*) {
      type : string;
      DefaultValue : "";
    }
  }
  CSVWrapper(CsvWrapper) {
    Repeatable : on;
    id(module_name) {
      Type : String;
    }
    id(design_id) {
      Type : String;
      IgnoreCase : On;
    }
  }
  DataWrapper(DataWrapper_with_no_value) {
    RowIdElement(port) {
      Type : String;
      repeatable : on;
    }
  }
  DataWrapper(DataWrapper_value) {
    RowIdElement(port) {
      Type : String;
      repeatable : on;
    }
    Value(period) {
      Type : time;
    }
  }
}

```

[set_config_value](#)

[add_config_element](#)

get_context

Context: unspecified, all contexts

Mode: all modes

Introspects the current context.

Usage

```
get_context [-atpg | -design_identifier | -edt  
            | -extraction | -failure_mapping | -full | -ijtag  
            | -logic_bist | -no_rtl | -no_sub_context  
            | -rtl | -scan | -scan_diagnosis | -scan_retargeting  
            | -silicon_insight | -test_points]
```

Description

When specified without an option, this command returns dft or patterns. When specified with the `-full` option, this command returns the entire context, including any sub-context. When specified with one of the other available options, this command returns 1 if the specified sub-context is active.

Arguments

- `-atpg`
An option that returns 1 when “`set_context -scan`” is specified. When `set_system_mode` analysis is run and no Logic BIST configuration is detected, the `-atpg` sub-context is set to 1.
- `-design_identifier`
An option that returns the specified or inferred `design_identifier` value.
- `-edt`
An option that returns 1 when “`set_context -scan`” is specified. When `set_system_mode` analysis is run and the EDT configuration is detected, the `-edt` sub-context is set to 1.
- `-extraction`
An option that returns 1 when the following conditions are met:
 - The “`set_context -ijtag`” command was specified.
 - The design was elaborated with the `set_current_design` command but no top-level ICL module existed at the time of elaboration.
 - The current system mode is setup.When the preceding conditions are present, the top-level ICL module is extracted when you run the “`set_system_mode` analysis” command. If there are no child ICL modules matched to design modules, the tool generates an error.
- `-failure_mapping`
An option that returns 1 when “`set_context -failure_mapping`” is specified.

get_context

- -full

An option that returns a string that fully describes the current context, sub-context(s), and additional switches. The -full option also returns the license option when the license was specified with the [set_context](#) command. This option can be used to save the current context to be restored later with the [set_context](#) command.

To save the full context, you can store it in a Tcl variable using this command:

```
set full_context [ get_context -full]
```

To restore the full context, use this command:

```
set_context {*} $full_context
```

The {*} prefix breaks the list of arguments into separate arguments for the [set_context](#) command.

- -ijtag

An option that returns 1 when “[set_context -ijtag](#)” is specified.

- -logic_bist

An option that returns 1 when “[set_context -scan](#)” is specified. When [set_system_mode](#) analysis is run and a Logic BIST configuration is detected, the -logic_bist sub-context is set to 1.

- -no_rtl

An option that returns 1 when “[set_context -no_rtl](#)” is either specified or inferred. It is inferred in all patterns contexts and in the dft -scan and -edt contexts.

- -no_sub_context

An option that returns 1 when the [set_context](#) was specified with no sub_context options such as -scan or -edt. The -rtl/-no_rtl options on the set_context command have no impact on the get_context -no_sub_context value.

- -rtl

An option that returns 1 when “[set_context -rtl](#)” is specified.

- -scan

An option that returns 1 when “[set_context -scan](#)” is specified.

- -scan_diagnosis

An option that returns 1 when “[set_context -scan_diagnosis](#)” is specified.

- -scan_retargeting

An option that returns 1 when “[set_context -scan_retargeting](#)” is specified.

- -silicon_insight

An option that returns 1 when “[set_context -silicon_insight](#)” is specified.

- -test_points

An option that returns 1 when “`set_context -test_points`” is specified.

Return Values

Returns dft or patterns when no option is specified. Returns 0 or 1 when an options is specified.

Examples

Example 1

In the following example, a script introspects the current context and displays an appropriate message.

```
if {[get_context] == "dft"} {
  if {[get_context -scan]} {
    puts "in dft scan context"
  } elseif {[get_context -edt]} {
    puts "in dft edt context"
  } else {
    if {[get_context -rtl]} {
      puts "in dft rtl context"
    } else {
      puts "in dft no_rtl context"
    }
  }
} else { ;# patterns -> get_context is patterns
  if {[get_context -scan]} {
    if {[get_context -atpg]} {
      if {[get_context -edt]} {
        puts "in patterns scan edt atpg context"
      } else {
        puts "in patterns scan atpg context"
      }
    } else { ;# logic_bist -> get_context -logic_bist is 1
      puts "in patterns scan logic_bist context"
    }
  } elseif {[get_context -ijtag]} {
    if {[get_context -extraction]} {
      puts "in ijtag icl_extraction context"
    } else {
      puts "in ijtag retargeting context"
    }
  } else { ;# scan_diagnostic
    puts "in scan_diagnostic context"
  }
}
```

Example 2

This demonstrates the result of the -full switch.

```
set_context dft -rtl
get_context -full

dft -rtl -design_identifier "rtl"
```

[report_context](#)

[set_context](#)

get_current_design

Context: all contexts

Mode: all modes

Returns a collection of one element that specifies the top-level design when previously set.

Usage

dft -no_rtl and patterns -no_rtl Contexts

```
get_current_design [-icl | -created_from_tcd | -created_from_icl]
```

dft -rtl and patterns -rtl Contexts

```
get_current_design [-icl | -top_config_dictionary | -created_from_tcd | -created_from_icl]
```

Description

Returns a collection of one element that specifies the top-level design when previously set.

The `get_current_design` command returns an empty collection when the top-level design has not been previously defined using the `set_current_design`.

Arguments

- `-icl`
An optional switch that returns the name of an ICL module object if that object exists. The switch returns an error if there is no ICL module associated with the current design.
- `-top_config_dictionary` (“`set_context context -rtl`” only)
An optional switch that returns the name and library of the configuration of VHDL top module. You use this switch to determine if the design was elaborated using a top-level configuration or using the top module directly. When the top module was not set via a configuration, it returns a null.

The format for the returned dictionary is:

```
config_name <name> library_name <library_name>
```
- `-created_from_tcd`
An optional switch that returns true if the *current_design* is created from a Tessent Core Description (TCD), otherwise it returns false.
- `-created_from_icl`
An optional switch that returns true if the *current_design* is created from an already-loaded ICL module that is associated with the *current_design*, otherwise it returns false.

Examples

Example 1

```
get_current_design
```

```
{ }  
  
read_verilog top.v  
set_current_design top  
get_current_design  
  
{top}  
  
puts [get_current_design]  
  
@45  
  
puts [get_single_name [get_current_design]]  
  
top  
  
if { [get_single_name [get_current_design]]== "top" } { puts "yes" }  
  
yes
```

The first `get_current_design` command returns an empty collection because no current design has been set. The second `get_current_design` command returns a collection consisting of the name of the top-level design that was previously set. The first “puts” command returns only the pointer (`@45`) to a collection in memory. The second “puts” command shows how to use the `get_single_name` command to return the name of the module object returned by `get_current_design`.

Example 2

This example shows how to use the `-top_config_dictionary` switch to determine if the design was elaborated using a top-level configuration or using a top module directly.

```
set top_config_dictionary [get_current_design -top_config_dictionary]  
if { $top_config_dictionary ne "" } {  
    set top_config_name [dict get $top_config_dictionary config_name]  
    set top_library_name [dict get $top_config_dictionary library_name]  
} else {  
    set top_module [get_current_design]  
}
```

Related Topics

[get_name_list](#)

[set_current_design](#)

get_current_mode

Context: patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis, patterns -failure_mapping

Mode: setup, analysis

Returns the current test mode, as specified by the set_current_mode command.

Usage

```
get_current_mode [-type]
```

Description

Returns the current test mode, as specified by the set_current_mode command.

If you do not include the -type switch, the command returns the name of the test mode. If you include the -type switch, this command returns the mode type.

Arguments

- -type
An optional switch that returns the mode type. Possible return values are: unwrapped, internal, external, and retargeting. For more information about these test modes, refer to the [set_current_mode](#) command description.

Examples

This example returns the test mode as “unwrapped.”

```
get_current_mode  
unwrapped
```

Related Topics

[set_current_mode](#)

get_current_physical_block

Context: dft -edt, dft -scan, dft -test_points, patterns -ijtag, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: setup, analysis

Returns the current physical block specified with the `set_current_physical_block` command.

Usage

```
get_current_physical_block
```

Description

Returns the current physical block specified with the `set_current_physical_block` command.

Arguments

None.

get_current_silicon_insight_setup

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Returns the currently selected SiliconInsight setup as specified in the TSI setup spec.

Usage

`get_current_silicon_insight_setup`

Arguments

None

Examples

`get_current_silicon_insight_setup`

`Sid(simdut)`

get_current_simulation_context

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Returns the name of the current simulation context.

Usage

```
get_current_simulation_context
```

Description

Returns the name of the current simulation context.

The `get_current_simulation_context` command returns the current simulation context. For a list of predefined simulation contexts, refer to [Table 6-8](#) on page 2291.

Arguments

None.

Examples

The following example shows how to set and return the current simulation context:

```
SETUP> get_current_simulation_context  
stable_after_setup  
  
SETUP> set_current_simulation_context stable_load_unload  
SETUP> get_current_simulation_context  
stable_load_unload
```

get_default_ssn_datapath_configuration

Context: all contexts

Mode: all modes

Retrieves an override setting of an ICL primary target on a SSN datapath.

Usage

```
get_default_ssn_datapath_configuration [-instance design_instance]  
    -target icl_pin_port_or_reg
```

Description

Retrieves a PDL value overriding a default setting of an ICL primary target on a SSN datapath.

Refer to the command “[set_default_ssn_datapath_configuration](#)” on page 2297 to learn more about the purpose and the use model of the default SSN datapath configuration and how `set_default_ssn_datapath_configuration` assigns settings to the PDL values of ICL targets to override their default state.

Arguments

- -instance *design_instance*
An optional switch and string pair that specifies the design instance portion of the instance/target pair from which to retrieve the PDL value. If you omit this switch, the tool treats the -target specification as relative to the current design.
- -target *icl_pin_port_or_reg*
A required switch and value pair that specifies a primary ICL input port, an ICL pin, or an ICL ScanRegister. The `icl_pin_port_or_reg` parameter can also specify a sub-range. Specify the target in the exact same way as assigned by the `set_default_ssn_datapath_configuration` command.

Examples

The following example sets two PDL values of two ICL targets and then retrieves their values.

```
SETUP> set_default_ssn_datapath_configuration -target cfginst.din -value 0b1101xx10  
SETUP> set_default_ssn_datapath_configuration -target ssnMuxCtrl -value Upper  
  
SETUP> get_default_ssn_datapath_configuration -target cfginst.din  
0b1101xx10  
SETUP> get_default_ssn_datapath_configuration -target ssnMuxCtrl  
Upper
```

get_defaults_value

Context: dft, patterns, unspecified

Mode: setup, analysis, insertion

Obtains the default value of a property as specified in one of the DefaultsSpecification(company | user | group)/DftSpecification or DefaultsSpecification(company | user | group)/PatternsSpecification wrappers.

Usage

```
get_defaults_value property_path_name  
    [-policy policy]  
    [-time_unit time_unit] [-number_format format]  
    [-is_specified] [-tolower] [-toupper]
```

Description

Obtains the default value of a property as specified in one of the DefaultsSpecification(company | user | group)/DftSpecification or DefaultsSpecification(company | user | group)/PatternsSpecification wrappers.

When the -policy option is not specified, it returns the value specified in the [DefaultsSpecification](#)(user) policy, the value specified in the group policy if not specified in the user policy, the value specified in the company policy if not specified in the user or group policy, or the tool default if not specified in any policy.

When automatically resolving the priority, the default value of the property is accessed.

Arguments

- ***property_path_name***
A required string that defines the path to a property without the “DefaultsSpecification()” prefix. For the DftSpecification, this path starts with “DftSpecification/”. For the PatternsSpecification, this path starts with “PatternsSpecification/”.
- -policy *policy*
An optional switch and value pair that defines from which DefaultsSpecification wrapper the default value is requested. If not specified, the command returns the value specified in the user policy, the value specified in the group policy if not specified in the user policy, the value specified in the company policy if not specified in the user or group policy, or the tool default if not specified in any policy.
- -time_unit *time_unit*
An optional switch and value pair that is only relevant when obtaining the value of a property of type time. This option enables you to request the time expressed in the units you want. For more information see the description of the [get_config_value](#) -time_unit option.

- `-number_format format`

An optional switch and value pair that is only relevant when obtaining the value of a property of type binary. This option enables you to request the binary number expressed in the format you want. For more information see the description of the [get_config_value](#) `-number_format` option.
- `-is_specified`

An optional Boolean option that specifies that you are not requesting the actual value of the property but instead requesting status on whether the property is specified or not in the given policy. If the `-policy` option is not specified, the tool returns 1 if it is specified in any of the policy wrappers. If the `-policy` option is not specified and the tool returns 0, then you know you are getting the tool default value.
- `-tolower`

An optional switch and value pair that is only relevant when obtaining the value of a property of type string. This option enables you to request the string with all upper-case letters converted to lower case.
- `-toupper`

An optional switch and value pair that is only relevant when obtaining the value of a property of type string. This option enables you to request the string with all lower-case letters converted to upper case.

Examples

The following example queries the default value of a property and then checks which policy specified it:

```
set p DftSpecification/IjtagNetwork/HostScanInterface/Block/scan_in?
get_defaults_value $p
my_scan_in

foreach policy {user group company} {
  if {[get_defaults_value $p -policy $policy -is_specified]} {
    break
  }
}
puts "$p is specified by policy $policy."
'DftSpecification/IjtagNetwork/HostScanInterface/Block/scan_in' is specified by policy
'group'.
```

Related Topics

[create_dft_specification](#)
[set_defaults_value](#)

get_design_level

Context: dft

Mode: setup, analysis, insertion

Returns the design level previously defined with the `set_design_level` command.

Usage

```
get_design_level
```

Description

Returns the design level previously defined with the [set_design_level](#) command.

When a new design is elaborated, the level goes back to being unspecified. In this case, the `get_design_level` command returns a null string. This command returns “chip” when you used “`set_design_level top`” or “`set_design_level chip`”.

Arguments

None

Examples

The following example queries the level of the current design and stores the result in a variable.

```
set design_level [get_design_level]
```

Related Topics

[set_current_design](#)

[set_design_level](#)

get_design_objects

Context: All

Mode: All

Returns a collection of design objects associated to the `object_ids` supplied.

Usage

```
get_design_objects {-from_ids object_ids | -from_objects from_objects}  
[-map_pseudo_ports]
```

Description

This command converts a list of *object_ids* or objects to a collection of objects. Each design object type (module, instance, port, pin, net, and pseudo_port) has a unique *object_id*, as described in the “[Hierarchical Design Data Model](#)” section.

The value of these attributes consists of a string followed by a colon and a unique integer per object type. The string is the name of the object type. For example, the object id of a module is `module:integer`. You use this unique string to construct a dictionary for objects, using the *object_id* as the key. You use the *object_ids* with the “`get_design_objects -from_ids`” command to get back to the objects. Using the *object_id* rather than the name of the object is more efficient and more robust because it is much shorter and does not change during synthesis.

The object names found inside a generate block in RTL change during synthesis. For example, the instance `u1` inside generate block `b1` has a name `b1.u1` in RTL but “`\b1.u1`” after quick synthesis. When you build a dictionary in analysis mode with the synthesized name as a key, you cannot find the object with that name in insertion mode because the RTL view is restored in insertion mode. When you store the *object_id*, you can find the object in either the synthesized view or the RTL view. See the example later for an illustration of this behavior.

Arguments

- **-from_ids *object_ids***

A required switch-value pair that is used to supply a Tcl list of *object_ids*. The *object_ids* of the objects are obtained using the “`get_attribute_value_list -name object_id`” command. An *object_id* can only be used to get back the objects for as long as the design remains elaborated in memory. There is no guarantee that an *object_id* for a given object remains the same the next time the design is elaborated. It is exactly like the `gate_id` of a `gate_pin` object that is only valid while the flat model is in memory. Never save a dictionary to disk containing *object_ids* and expect the *object_ids* to have meaning when you reload the dictionary at a later time. The *object_ids* are only stored in memory and reused while the design remains in memory as shown in the example.

- **-from_objects from_objects**

A required switch-value pair that is used to supply a Tcl list of objects. The *from_objects* may contain ports, pseudo_ports, pins, nets and gate_pins. A port, pin or net is passed through to the result collection.

- **-map_pseudo_ports**

An optional switch that specifies a pseudo_port is mapped to the corresponding pins or nets, otherwise it is just passed through to the result collection. A gate_pin is mapped to the corresponding port, pseudo_port, pin or net. If it maps to a pseudo_port and “-map_pseudo_ports” is specified that pseudo_port is further mapped to the corresponding pins or nets as described above.

Examples

Example 1

The following example shows that the name of an object changes with synthesis but the *object_id* does not. The *object_id* stored in analysis from the synthesized view is valid to get the RTL object in insertion mode.

```

SETUP> set design_mods [get_modules -of_type design]
SETUP> set_attribute_value $design_mods -name synthesize_before_analysis
SETUP> set_system_mode analysis

// -----
// Begin RTL synthesis.
// -----
// Module 'FF' synthesized.
// Module 'elt' synthesized.
// Module 'subBlock1' synthesized.
// Module 'subBlock2' synthesized.
// RTL synthesis completed, synthesized modules=4, Time=1.83 secs.
// -----

ANALYSIS> set subBlock1_instances [get_instance -of_module subBlock1]
ANALYSIS> set subBlock1_instance1 [index_collection $subBlock1_instances 1]

ANALYSIS> set name [get_single_name $subBlock1_instance1]
ANALYSIS> set object_id [get_attribute_value_list $subBlock1_instance1 \
                    -name object_id]

puts [get_single_name [get_instance [list $name]]] option1.subBlock2_I2 /subBlock1
puts [get_single_name [get_design_objects -from_ids $object_id] \
      option1.subBlock2_I2 /subBlock1

ANALYSIS> set_system_mode insertion

# The object name changed when restoring the RTL view but the
# object_id remained the same

INSERTION> puts [get_single_name [get_instance [list $name]]]

// Warning: No result.

```

```
INSERTION> puts [get_single_name [get_design_objects -from_ids $object_id]] \  
option1.subBlock2_I2/subBlock1
```

Example 2

The following example shows how to map pseudo ports and gate_pins to port, pin and net objects. Any pin, port or net objects found in \$col is passed through unchanged. Any gate_pin object is mapped to its associated port, pin, net objects. If the gate_pin objects is inside a cell and has no associated port, pin, or net objects, it is silently deleted. Finally, any pseudo_port objects found in \$col is mapped to its associated port, pin, net object because the -map_pseudo_ports option is used. When the switch is not used, the pseudo_port objects are passed through unchanged.

```
set design_object [get_design_objects -from_objects $col1 -map_pseudo_ports]
```

Related Topics

[get_attribute_value_list](#)

get_design_sources

Context: unspecified, all contexts

Mode: setup, analysis, insertion

Returns the pathnames or file extensions previously specified with the `set_design_sources` command.

Usage

```
get_design_sources [-format {verilog | icl | tcd_bscan | tcd_scan | tcd_fbox  
| tcd_memory | tcd_memory_cluster}]  
[-path_list | -extension_list | -file_dictionary | -search_design_load_path]
```

Description

Returns the pathnames or file extensions previously specified with the `set_design_sources` command.

By default, the `get_design_sources` command returns a list of paired values that specify the pathnames to all design sources. The first item in the pair is `-v` or `-y` to indicate whether the pathname is a file or a directory, respectively. This is useful when you want to add additional design sources because any invocation of the `set_design_sources` command overwrites previous invocations.

Arguments

- `-format {verilog | icl | tcd_bscan | tcd_scan | tcd_fbox | tcd_memory | tcd_memory_cluster}`
An optional switch and literal pair that enables you to choose the output format. By default, the command specifies Verilog modules.
- `-path_list`
An optional switch that returns a list of pathnames. This is the default.
- `-extension_list`
An optional switch that returns a list of file extensions for the specified format.
- `-file_dictionary`
An optional switch that returns a Tcl dictionary that contains information about the design files that the tool has read and written. This can be useful, for example, if you need to create a script for a downstream tool that needs to read the correct design files with the correct options in the correct sequence. For a description of the file dictionary format, see the description of the `<design_name>.design_source_dictionary` component in [dft_inserted_designs](#). You can use this switch only when you also specify “`-format verilog`”.
- `-search_design_load_path`
An optional switch that returns a Boolean value (on or off) that indicates whether the `set_design_sources -search_design_load_path` option is enabled. You can use this switch only when you also specify “`-format icl`”.

Examples

This example clears previous `set_design_sources` commands before setting new design sources, and then returns the list of pathnames and the list of extensions:

```
SETUP> set_design_sources -clear  
SETUP> set_design_sources
```

```
// No -v/-y files/directories specified.
```

```
SETUP> set_design_sources -v MODB.v MODC.v -y /u/joe/testcases -extensions .v .vhd  
SETUP> get_design_sources -path_list -v MODB.v -v MODC.v -y /u/joe/testcases  
SETUP> get_design_sources -extension_list .v .v.gz .vhd .vhd.gz
```

Related Topics

[report_design_sources](#)

[set_design_sources](#)

get_dfm_rules

Context: patterns -scan_diagnosis

Mode: analysis

Returns a TCL list of the DFM rules contained in the layout database.

Usage

```
get_dfm_rules [-header | -col columns...]
```

Description

Returns a TCL list of the DFM rules contained in the layout database.

By default, for each rule the tool returns the id, rule name, layer, and type.

For more information about DFM rules, see “[Diagnosis for Design for Manufacturability Analysis](#).”

Arguments

- **-header**
An optional switch that returns a list of available column names.
- **-col *columns...***
An optional switch that specifies the column names you want to use for the DFM rule information in the list.

Examples

Example 1

The following example sets the available column names of the DFM report table into a TCL variable and displays the column names.

```
open_layout MyLayoutDB
set columns [ get_dfm_rules -header ]
puts "columns: $columns"

columns: id rule layer type
```

Example 2

The following example creates a custom report by inspecting the DFM rules:

```
foreach { id rule_name layer_name type_name } [ get_dfm_rules ] {
  puts "$id $rule_name $layer_name $type_name"
}
```

```
1 minimum_space_4_line_route1 route_1 BRIDGE
2 metal_cross_edge_route1 route_1 OPEN
3 low_density_min_space_route2 route_2 BRIDGE
4 half_comb_route3 route_2 OPEN
5 metal_cross_edge_route1 route_3 OPEN
6 corner_to_interior_metal4 route_4 BRIDGE
7 divergent_line_with_jog_metal5 route_5 BRIDGE
8 metal_cross_edge_route1 route_5 OPEN
9 route_5_barbell route_5 OPEN
10 route_2_between_vias route_2 OPEN
```

Example 3

The following example customizes the columns for the report:

```
foreach { r t } [ get_dfm_rules -col rule type ] {
  puts "$r $t"
}

minimum_space_4_line_route1 BRIDGE
metal_cross_edge_route1 OPEN
low_density_min_space_route2 BRIDGE
half_comb_route3 OPEN
metal_cross_edge_route1 OPEN
corner_to_interior_metal4 BRIDGE
divergent_line_with_jog_metal5 BRIDGE
metal_cross_edge_route1 OPEN
route_5_barbell OPEN
route_2_between_vias OPEN
```

Related Topics

[report_dfm_rules](#)

get_dft_cell

Context: dft

Mode: all modes

Retrieves the named sets of cells to use when test hardware must be inserted (as a Tcl list of the currently available cell selection names), or a particular cell given the name and required cell function of a specified set of cells.

Usage

```
get_dft_cell -available_cell_selection_names | -default_cell_selection_name | function_name
  [-with_async_enable] [-with_async_disable] [-with_set] [-with_reset] [-length length]
  [-cell_selection_name dft_cell_selection_name] [-inputs number]
  [-with_inverted_inputs number_inverted_inputs] [-silent]
```

Description

Retrieves the named sets of cells to use when test hardware must be inserted (as a Tcl list of the currently available cell selection names), or a particular cell given the name and required cell function of a specified set of cells.

If only one set (one cell_selection) exists, or the “set_cell_library_options -default_cell_selection_name” command was used to set the default cell selection, then the -cell_selection_name switch is optional for retrieving a cell of a given function. Otherwise, -cell_selection_name must be used to identify a specific cell selection.

This command is very useful in enabling you to write a technology-independent command. After you have retrieved the cell module using the get_dft_cell command, you can use the function attribute on the ports of the module to find the ports you want to connect to.

For more information on Tessent cell library attributes, see the [Tessent Cell Library Manual](#). More specifically, refer to the dft_cell_selection wrapper description described in the [Cell Selection](#) section as well as the function attribute described in [Pin Attributes](#).

You can see a list of the available DFT cell functions by using the “help get_dft_cell” command. Each of the listed functions corresponds one for one with the elements documented in the dft_cell_selection wrapper found in the [Cell Selection](#) section of the *Tessent Cell Library Manual*. Many basic functions are learned and automatically assigned to a dft_cell_selection wrapper named default when your library does not contain a dft_cell_selection wrapper.

Note

 If your Tessent cell library contains only ATPG model information but you have a *cell.lib* file in the original LogicVision format, you can load it natively using the [read_cell_library](#) command, and this populates the dft_cell_selection wrapper.

Arguments

- **-available_cell_selection_names**
An optional switch that specifies for the tool to return a Tcl list of names of the currently available DFT cell selections. If none are parsed and one is learned by default, it returns a list with the single element “default”. If there is no cell selection parsed and no default is created (for example, if no library is loaded) it returns null.
- **-default_cell_selection_name**
An optional switch that returns null unless there is only one cell selection or the [set_cell_library_options -default_dft_cell_selection_name](#) command was used to define a cell selection as the default.
- ***function_name***
A optional string that specifies the DFT cell function from the specified or default `dft_cell_selection` to return. If the specified function does not exist in the specified `dft_cell_selection`, the tool issues an error and lists the `dft_cell_selection` names that contains the requested `function_name`.
- **-with_asynch_enable**
An optional switch that applies to `clock_gating_and` as well as `clock_gating_or` and specifies to return a cell with an asynchronous input to enable clocking at the cell output.
- **-with_asynch_disable**
An optional switch that applies to `clock_gating_and` as well as `clock_gating_or` and specifies to return a cell with an asynchronous input to turn off clocking at the cell output.
- **-with_set**
An optional switch that applies to `active_high_latch`, `active_low_latch`, `posedge_dff`, `negedge_dff`, `posedge_scan_cell`, `negedge_scan_cell`, `posedge_synchronizer_cell` or `negedge_synchronizer_cell` and specifies to return a cell with an asynchronous input to set the cell’s state to “1” (high). For all types except `posedge_synchronizer_cell` and `negedge_synchronizer_cell`, if a cell with exactly what is requested does not exist, the command returns null. However, for the synchronizer cells, the command returns a cell if it has all the features requested and can be tied off outside to produce the requested cell. For example, if a `synchronizer_cell` with no asynchs is requested (no `-with_set` or `-with_reset` switches) and none exists, but a `sync_cell` with one or more asynchs does exist, the command returns it. Similarly, if a `sync_cell -with_set` is requested, and none with only a set exists, but one with both asynchs does exist, the command returns it.
- **-with_reset**
An optional switch that applies to `active_high_latch`, `active_low_latch`, `posedge_dff`, `negedge_dff`, `posedge_scan_cell`, `negedge_scan_cell`, `posedge_synchronizer_cell` or `negedge_synchronizer_cell` and specifies to return a cell with an asynchronous input to reset the cell’s state to “0” (low). For all types except `posedge_synchronizer_cell` and `negedge_synchronizer_cell`, if a cell with exactly what is requested does not exist, the command returns null. However, for the synchronizer cells, the command returns a cell if it

has all the features requested, and can be tied off outside to produce the requested cell. For example, if a synchronizer_cell with no asynchs is requested (no -with_set or -with_reset switches) and none exists, but a sync cell with one or more asynchs does exist, the command returns it. Similarly, if a sync_cell -with_reset is requested, and none with only a reset exists, but one with both asynchs does exist, the command returns it.

- -length *length*

A switch and integer pair that specifies the length of a posedge_synchronizer_cell or a negedge_synchronizer_cell. The length is the number of DFFs in the synchronizer cell and can be specified using a single number or a number:number range. If the dft_cell_selection does not contain a synchronizer_cell of the length specified, the command returns an empty string.

- -cell_selection_name *dft_cell_selection_name*

A switch and string pair that specifies the name of a currently available cell selection to retrieve cells from. This could be a technology name, for example. This switch is optional if only one dft_cell_selection wrapper is currently loaded. If this switch is not specified and more than one dft_cell_selection wrapper exists, the tool issues an error. Similarly, if an invalid technology is specified, the tool issues an error and lists all available dft_cell_selection names.

- -inputs *number*

An optional switch and integer pair that specifies the number of inputs on the model. The default number is 2. The default is ignored except in the case of symmetrical primitives {and, nand, or, nor, xor}. The default for symmetrical primitives is 2 unless the -inputs number pair specifies an integer greater than 2; in this case the tool returns a cell with the specified number of inputs if one exists in the specified technology.

- -with_inverted_inputs *number_inverted_inputs*

An optional switch and integer pair that specifies the number of inverted inputs of the total inputs specified with the -inputs switch. At least one input must be non-inverting. This switch can only be used when *function_name* is “and” or “or”.

- -silent

An optional switch that specifies to suppress the error message and returns an empty collection.

Return Values

Returns the module objects when no errors are present.

Examples

Example 1

In the following example, the command queries which cell model is available in the tech_name_1 dft_cell_selection wrapper to be used as a clock_buffer.

```
get_dft_cell clock_buffer -cell_selection_name tech_name_1
```

```
{my_buff}
```

Example 2

In the following example, the command queries which 4-input cell model is available to be used as an and gate.

get_dft_cell and -input 4

```
{and_4}
```

Example 3

In the following example, multiple `dft_cell_selection` wrappers exist but the `-cell_selection_name` switch is not specified. As a result, the tool returns an error and lists the available `dft_cell_selection` names that exist in the library.

get_dft_cell and

```
// Error: Multiple cell_selection(<selection_name>) exist.  
// Must specify -cell_selection_name followed by one of :  
// tech_name_1  
// tech_name_2  
// tech_name_3
```

Example 4

In the following example, an invalid technology is specified. As a result, the tool returns an error and lists the available technologies.

get_dft_cell and -cell_selection_name foo

```
// Error: cell_selection(foo) does not exist.  
// -cell_selection_name must currently be followed by one of :  
// tech_name_1  
// tech_name_2  
// tech_name_3
```

Example 5

In the following example, a procedure called `intercept_with_cell_body` is created to enable intercepting ports, nets, or pins that are either sinks or drivers. The second argument is a `cell_selection` type string that uses the `get_dft_cell` command to obtain the corresponding cell from the library, thereby making this command technology-independent. To understand the purpose of each section, read the comments in the commented section headers.

Note, in Section 3, the port attribute called ‘function’ is used to determine the port names to connect on the selected dft cell. You can also refer to the example for the [register_tcl_command](#) to see how you can create a cleaner external interface to this command with proper option parsing and help messages.

get_dft_cell

```
#####
### This array is to not repeat interception into repeated module
### instances when auto_uniquify_edited_modules is off
#####

variable insertion_parent_leaf_instance_array

get_dft_cell_selection_mapping

Context: dft

Mode: all

Returns the library cell selection associated to the specified power domain.

Usage

```
get_dft_cell_selection_mapping -power_domain_name power_domain_name
```

Description

Returns the library cell selection associated to the specified power domain.

Arguments

- `-power_domain_name power_domain_name`
A required switch and string pair that specifies the value of `power_domain_name` attribute for which the associated library cell selection is to be returned.

Examples

get_dft_info_dictionary

Context: dft, patterns

Mode: setup, analysis

Creates a Tcl dictionary containing the information about the DFT inserted in the RTL that must be considered during scan insertion.

Usage

```
get_dft_info_dictionary [[-example_usage_script]
    [-process_modules_with_chains_not_active_by_default]]
```

Description

This command creates a Tcl dictionary containing the information about the DFT inserted in the RTL that must be considered during scan insertion. When you are using Tessent Scan for scan insertion, the information about the DFT logic you inserted into the RTL is automatically understood and used during scan insertion. If you are performing the scan insertion as part of synthesis, the dictionary created by this command can be used to import the information into the synthesis tool.

Note that the DFT info dictionary is automatically stored into the [dft_inserted_designs](#) directory when the [extract_icl](#) command is called with the `-write_in_tsdb` switch set or defaulting to on.

The format of the dictionary is illustrated in the syntax summary below. The version, `dft_signals`, `modules_with_chains`, `modules_with_chains_not_active_by_default`, `non_scannable_instance_list` and `edt_instances` keys always exist even if their values are empty.

```
set tesseract_dft_info_dict {
  version 1
  dft_signals {
    dft_signal_name {
      connection_node_name node_name
      connection_node_type port|pin
      forced_value_in_pre_scan_drc 0|1
    }
  }
  modules_with_chains {
    module_name {
      pre_scan_drc_on_boundary_only 0|1
      module_type normal|memory|occ
      is_hard_module 0|1
      internal_scan_only 0|1
      allow_scan_out_retiming 0|1
      instance_list {inst_name ...}
      scan_en_ports|ltest_en_ports|set_reset_ports {
        port_name {
          active_polarity 0|1
        }
      }
      clock_ports {
        port_name {
          off_state 0|1
        }
      }
      clock_out_ports_or_pins {
        port_or_pin_name {}
      }
      scan_chains {
        scan_chain_name {
          length auto|int
          scan_in_port port_name
          scan_in_clock_name port_name
          scan_in_clock_inversion 0|1
          scan_out_port port_name
          scan_out_clock_name port_name
          scan_out_clock_inversion 0|1
        }
      }
    }
  }
  modules_with_chains_not_active_by_default {
    // structure identical to modules_with_chains wrapper
  }
  non_scannable_instance_list {inst_name ...}
  edt_instances {
    instance_name {
      edt_module_name module_name
      scan_chains {
        chain_name {
          scan_in_port port_name
          scan_out_port port_name
        }
      }
    }
  }
}
```

```
}
```

Arguments

- `-example_usage_script`

An optional switch used to request an example usage script that you can use as a starting example to convert the dictionary into the specific commands of your synthesis tool. The places you are expected to enter tool-specific commands are identified with the `###` comments.

- `-process_modules_with_chains_not_active_by_default`

An optional switch that you can specify along with the `-example_usage_script` switch to generate an example usage script that includes processing the `modules_with_chains_not_active_by_default` key

Examples

The following example shows the content of an example usage script to be used with the DFT info dictionary created as part of the [extract_icl](#) command:

get_dft_signal

Context: dft, patterns

Mode: setup, analysis, insertion

Obtains the source of a DFT signal or various aspects about the DFT signal.

Usage

```
get_dft_signal {-list | -source_node pin_port_spec
  | name [-at at_value | -exists | -list_of_parent_instances
  | -scan_mode_type] [-parent_instance parent_instance]}
  [-usage usage] [-silent]
```

Description

Obtains the source of a DFT signal or various aspect about the DFT signal. Between the time a DFT signal was added and `process_dft_specification` has completed its run, the existence of a DFT signal can be checked with the `-exists` switch, but the signal's location cannot be obtained until it is actually created.

You can query the location of a DFT signal within the `process_dft_specification.post_insertion` callback as the DFT signal is created before the proc is called. As you can see in the example below, the `get_dft_signal` command is useful at several stages of the flow to obtain the location of a previously added DFT signal.

Arguments

- **-list**
A Boolean switch that specifies to return the list of existing or to-be-created DFT signals. The switch can be combined with the `-usage` switch to limit the list to a single usage as shown in the example.

When the `-list`, `-exists`, `-list_of_parent_instances`, and `-scan_mode_type` switches are not specified, the command returns a collection containing the object on which the DFT signal exists.
- **-source_node** *pin_port_spec*
A switch-value pair used to specify the name of a single port or pin object or a collection containing a single port or pin object. When used, the command returns the name of the DFT signal added to the specified node. If no DFT signals were added on the specified node, an error is generated unless the `-silent` switch is used, in which case the error message is suppressed, and an empty string is returned.
- *name*
A string argument used to specify the name of a DFT signal for which you want its location or other aspect such as its existence, or the type of `scan_mode` it is.

- *-at at_value*

A switch-value pair that you use to access a DFT signal location at specified point in the DFT signal path. The DFT signal can have several instruments on its path, such as pads or LBIST, and SSH. When you do not use this switch, the command returns the location at the end of the DFT signal path.

The *at_value* can be one of the following values:

source

Returns the pin or port at the start of the DFT signal path.

source_pad_dft_driver

Returns the location of the DFT signal at the output of boundary logic (pad, auxiliary pin, or pad followed by an auxiliary pin).

lbist_dft_driver

Returns the DFT signal location at the output of an LBIST instrument instance where the signal is available.

ssh_dft_driver

Returns the DFT signal location on the output of ScanHost instrument instance where the signal is available.

current_dft_driver

Returns the end location of the DFT signal path, just as when you omit the *-at* switch. After SSH insertion, *current_dft_driver* points to *ssh_dft_driver*.

- *-exists*

A Boolean switch used to specify that a 1 should be returned if the specified DFT signal name exist and when the *-usage* switch is also specified that the DFT signal is of the specified usage. A "0" is returned otherwise.

- *-list_of_parent_instances*

A Boolean switch that requests the list of parent instances in which the DFT signal exists. A null value in the list represents the top module. This option is only valid when combined with the name *edt_clock* and *shift_capture_clock* as those are the only two signals that may have several copies located in different parent instances. See the [add_dft_signals](#) *-parent_instance* switch description for more details.

- *-scan_mode_type*

A Boolean switch used to request the type of DFT signal having the usage *scan_mode*. The returned values are unwrapped, internal, external, or retargeting when the DFT signal has the usage *scan_mode*. The return value is a null string when the DFT signal has a usage other than *scan_mode*.

- *-parent_instance parent_instance*

A switch-value pair used to specify a parent instance in which the DFT signal is to be located. This option is only valid when combined with the name *edt_clock* and

get_dft_signal

shift_capture_clock as those are the only two signals that may have several copies located in different parent instances. See the [add_dft_signals](#) -parent_instance switch description for more details.

- -usage *usage*

A switch-value pair that is used to limit the DFT signals to a specified usage. The five permitted usages are: global_dft_control, logic_test_control, scan_mode, dynamic, static_ijtag. The usage static_ijtag means the DFT signal was added with -type static_dft_control and with either the “-create_with_tdr” switch or with the “-source_node port -make_ijtag_port” switches, which makes it controllable by ijtag.

When combined with the -list switch, it restricts the list to the DFT signal of the specified usage. When combined with the -exists switch, the command only returns “1” if the DFT signal exists and is of the specified usage.

- -silent

A Boolean switch that suppresses the error message that is normally generated when the specified DFT signal does not exist or is not of the requested usage. Instead of generating an error, the tool returns an empty collection.

Examples

The following example illustrates the usage of the various switches:

```
set_context dft -rtl

```

Error message when the requested signal does not exist:

```
catch {get_dft_signal junk}
// Error: The DFT signal named 'junk' does not exist. Run the
// 'report_dft_signals' command for more information.
```

get_dft_signal

Error message when the requested signal is of the wrong usage:

```
catch {get_dft_signal ltest_en -usage scan_mode}  
// Error: The DFT signal named 'ltest_en' is for usage  
// 'logic_test_control' instead of 'scan_mode'.
```

Error message suppressed when -silent is used:

```
get_dft_signal ltest_en -usage scan_mode -silent
```

The -unmapped_across_pad parameter usage and comparison:

```
add_dft_signals scan_en -source_node gpio3  
get_dft_signals scan_en  
{gpio3_pad/o}  
get_dft_signal scan_en -unmapped_across_pad  
{gpio3}
```

get_dft_signals_option

Context: dft -rtl, dft -no_rtl

Mode: setup, analysis, insertion

Returns the current setting specified by the set_dft_signals_options command.

Usage

get_dft_signals_option **-disable_for_functional_safety**

Description

Returns the current setting specified by the corresponding option and the set_dft_signals_options command.

Arguments

- **-disable_for_functional_safety**

A required switch that returns the current setting for this option. See “[set_dft_signals_options](#)” on page 2320 for possible return values.

Examples

The following example indicates that gating and monitoring logic for single-event upsets (SEUs) in test data registers (TDRs) is not created. The TDR registers fan out directly to functional logic.

```
SETUP> get_dft_signals_option -disable_for_functional_safety  
off
```

get_dft_specification_requirement

Context: dft patterns

Mode: all modes

Returns the requirements set using the `set_dft_specification_requirements` command.

Usage

```
get_dft_specification_requirement {-memory_bist | -tck_injection | -memory_bisr_chains |  
-memory_bisr_controller | -boundary_scan | -ac_boundary_scan | -logic_test |  
-add_test_clock_on_ssh | -memory_bisr_host_list | -bisr_segment_order_file |  
-host_scan_interface_type | -design_type}
```

Description

Returns the requirements set using the [set_dft_specification_requirements](#) command.

Arguments

- `-memory_bist`
An option that requests the value of the `set_dft_specification_requirements -memory_bist` option.
- `-tck_injection`
An option that requests the value of the `set_dft_specification_requirements -tck_injection` option.
- `-memory_bisr_chains`
An option that requests the value of the `set_dft_specification_requirements -memory_bisr_chains` option.
- `-memory_bisr_controller`
An option that requests the value of the `set_dft_specification_requirements -memory_bisr_controller` option.
- `-boundary_scan`
An option that requests the value of the `set_dft_specification_requirements -boundary_scan` option.
- `-ac_boundary_scan`
An option that requests the value of the `set_dft_specification_requirements -ac_boundary_scan` option.
- `-logic_test`
An option that requests the value of the `set_dft_specification_requirements -logic_test` option.

- **-add_test_clock_on_ssh**
An option that requests the value of the `set_dft_specification_requirements -add_test_clock_on_ssh` option.
- **-memory_bisr_host_list**
An option that requests the value of the `set_dft_specification_requirements -memory_bisr_host_list` option.
- **-bisr_segment_order_file**
An option that requests the value of the `set_dft_specification_requirements -bisr_segment_order_file` option.
- **-host_scan_interface_type**
An option that requests the value of the `set_dft_specification_requirements -host_scan_interface_type` option.
- **-design_type**
An option that requests the value of the `set_dft_specification_requirements -design_type` option.

Examples

The following example queries the value of the `-memory_test` option.

```
get_dft_specification_requirement -memory_bist  
off  
  
set_dft_specification_requirement -memory_test on  
get_dft_specification_requirement -memory_bist  
auto
```

Related Topics

[set_dft_specification_requirements](#)

get_drc_handling

Context: unspecified, all contexts

Mode: all modes

Retrieves the DRC handling status for the DRC with the specified name.

Usage

```
get_drc_handling drc_name [-auto_fix]
```

Arguments

- *drc_name*
A required string that specifies the name of the of the DRC you for which you want the DRC handling status.
- -auto_fix
An optional switch that enables you to see if the DRC supports auto fixing of the violation. If you registered your own custom DRC using the [register_drc](#) command and you used the -allow_auto_fix switch, this switch returns 1 unless you explicitly turned off auto fixing using the “[set_drc_handling](#) -auto_fix” command. It always returns 0 for a DRC that does not permit auto fixing. Use this command in the body of your custom DRC to know if the violation should be reported or auto fixed.

get_equivalent_editable_node

Context: dft

Mode: setup, analysis, insertion

Checks if a node is editable. If the node is not editable, then returns the node's editable equivalent node if it exists.

Usage

get_equivalent_editable_node *node_spec*

Description

The `get_equivalent_editable_node` command accepts a pin, port, net, pseudo_port or gate_pin objects as its argument.

If the object is a pseudo_port or a gate_pin, the tool maps it to its corresponding port, pin, or net object. If the object is a pin that is on or inside an instance created by RTLCC, or inside a hard module or a cell or if the object is a net that is inside an instance created by RTLCC, or inside a hard module or a cell, the tool maps it to an equivalent node in the editable region if one exists.

If the object cannot be mapped to an editable object, an empty collection is returned. Use this command when you are using the synthesized view to perform some analysis and then you want to perform edits on the RTL view.

Arguments

- *node_spec*

A required string used to specify the name of a pin, port, net, pseudo_port or gate_pin object or a collection containing a single pin, port, net, pseudo_port or gate_pin object.

Examples

The following example shows the use of the command to map various nodes to its editable equivalent:

Pin on a synthesized instance:

```
set map [get_equivalent_editable_node ex2_cell/rtlcc0_1/sel_0]
set type [get_attribute_value_list $map -name object_type]
puts "$type [get_single_name $map]"
pin ex2_cell/c
```

Pin on a normal instance:

```
set map [get_equivalent_editable_node ex2_cell/a]  
set type [get_attribute_value_list $map -name object_type]  
puts "$type [get_single_name $map]"  
pin ex2_cell/a
```

Pseudo_ports are mapped to their associated design objects:

```
puts [get_single_name [get_equivalent_editable_node pseudo_a]]  
ex1_i1/a
```

A gate_pin is mapped to its pseudo port then to the pin:

```
puts [get_single_name [get_equivalent_editable_node  
ex1_i1/y
```

get_fanins

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Returns a collection of all requested objects found in the fan-in of the specified pin, net, or port object.

Usage

```
get_fanins obj_spec [-stop_on {cell_pin | net | pin}] [-silent]
```

Description

Returns a collection of all requested objects found in the fan-in of the specified pin, net, or port object.

When *<obj_spec>* is an output or inout pin of a cell, the command reports all input or inout pins on the same cell that are in the combinational fan-in of the output or inout pin.

Note

 When you specify the “-stop_on pin” option, the fan-in direction of an inout pin is toward the inside of the instance.

The -stop_on option specifies object types upon which the tracing should stop. It does not mean that the returned collections contain only objects of the specified type because the tracing may stop before reaching the specified type. For example, a pin may be connected to a dangling net. The net is reported as the object on the fan-in of the pin even if -stop_on is specified as *cell_pin*. If the net had not been dangling and it had a driver, the *get_fanins* command would not have stopped on the net and would have continued to walk the fan-in path.

The *get_fanins* command returns an empty collection when there is no fan-in. The fan-in of an input port is null. When the fan-in of an input pin is an empty collection, the pin is either unconnected or tied. Use the *tie_value* attribute to see if it is tied to 0 or 1 or unconnected.

The *get_fanins* command does not use simulated values and only considers connectivity of the hierarchical data model. You can use the [trace_flat_model](#) command to perform tracing on the flat model with simulation conditions considered.

Arguments

- *obj_spec*

A required value that specifies a Tcl list of one or more net, pin, port, or *pseudo_port* names; or a collection of one or more net, pin, port, or *pseudo_port* objects.

get_fanins

- `-stop_on {cell_pin | net | pin}`

An optional switch and literal pair that specifies the following:

- When `-stop_on` is set to `cell_pin` (the default), the fan-in walk traverses nets and design pins but stops on pins of cells or primitives in the fan-in of the object. The walk may still, however, stop on a net or a design pin when the net or design pin does not have a fan-in.
- When `-stop_on` is set to `net`, the fan-in walk traverses through one level of “assign” statements and stops on the net connected to the start pin.
- When `-stop_on` is set to `pin`, the fan-in walk traverses nets and reports the pin in the fan-in of the object. This could be an input or inout pin above the object or an output or inout pin on child instances. The walk may still, however, stop on a net if the net does not fan-in to pins.

- `-silent`

An optional switch that suppresses the error that is normally generated if any object within `obj_spec` does not exist, in which case it is ignored.

Examples

Example 1

The following example shows a series of `get_fanins` command invocations of the circuit example shown in [Figure 4-4](#).

```
# find net connected to pin u4/I5
get_fanins u4/I5 -stop_on net
```

```
{n3}
```

```
#Find cell_pin in the fan-in of u4/I5
get_fanins u4/I5
```

```
{u3/Y}
```

```
#Find pin in the fan-in of u4/I5. Returns cell pins as there is no design pins before it
get_fanins u4/I5 -stop_on pin
```

```
{u3/Y}
```

```
#Find pin in the fan-in of u4/u1/A0
get_fanins u4/u1/A0 -stop_on pin
```

```
{u4/I1}
```

```
#Find all nets connected to the D pin of dff modules
get_fanins [get_pins -filter {module_name == "dff" && leaf_name == "D"}] -stop_on net
```

```
{I3 n6 u4/n2 u4/n3 u4/u5/n1 u4/u5/I3 u5/n1}
```

```
#Find pins in the fan-in of an output pin of a cell
get_fanins u1/Y
```

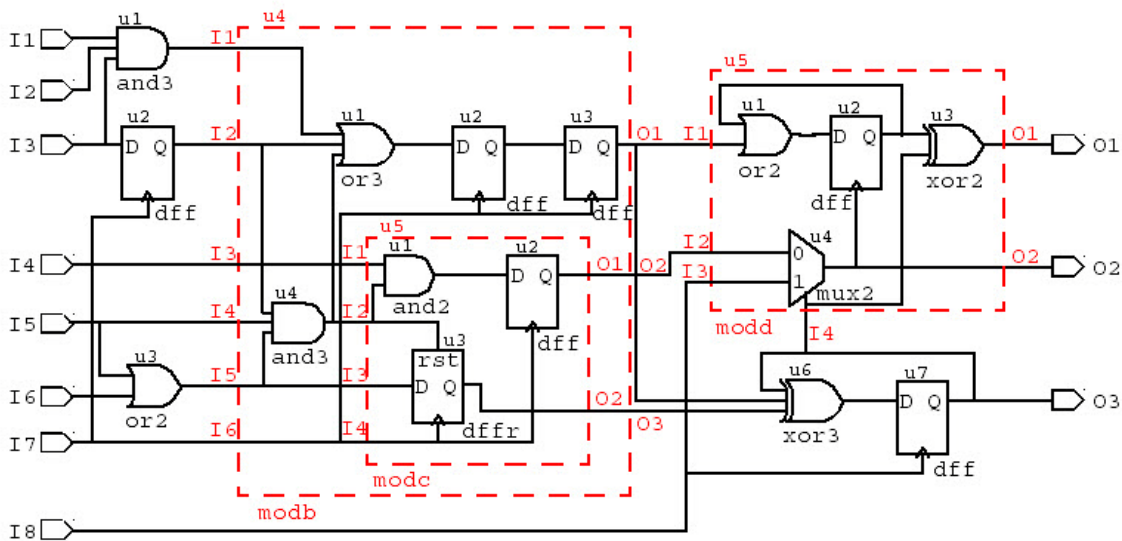

```
{u1/A0 u1/A1 u1/A2}
```

Example 2

The following example adds an internal primary input (pseudo_port). Based on the example circuit shown in [Figure 4-4](#), it then returns the collection of objects found in the fan-in of both of the pseudo_port's underlying pins.

```
add_primary_inputs {u4/I4 u4/I5} -internal -pseudo_port_name user_pi1
get_fanins user_pi1
{I5 u3/Y}
```

get_fanouts

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Returns a collection of all requested objects found in the fanout of the specified pin, net, or port object.

Usage

```
get_fanouts obj_spec [-stop_on cell_pin | net | pin] [-silent]
```

Description

Returns a collection of all requested objects found in the fanout of the specified pin, net, or port object.

When *<obj_spec>* is an input pin of a cell, the command reports all output or inout pins on the same cell that are in the combinational fanout of the input pin.

Note

When you specify the “-stop_on pin” option, the fanout direction of an inout pin is toward the outside of the instance.

The -stop_on option is used to specify object types upon which the tracing should stop. Specifying this option does not mean that the returned collections only contain objects of the specified type, because the tracing may stop before reaching the specified type. For example, a pin may be connected to a dangling net. The net is reported as the object on the fanout of the pin even if -stop_on is specified as cell_pin. If the net had been connected to other pins, the get_fanouts command would not have stopped on the net and would have continued to walk the fanout path.

The get_fanouts command returns an empty collection when there is no fanout. The fanout of an output port is null.

The get_fanouts command does not use simulated values and only considers connectivity of the hierarchical data model. You can use the [trace_flat_model](#) command to perform tracing on the flat model with simulation conditions considered.

Arguments

- *obj_spec*

A required value that specifies a Tcl list of one or more net, pin, port, or pseudo_port names; or a collection of one or more net, pin, port, or pseudo_port objects.

- `-stop_on cell_pin | net | pin`

An optional switch and literal pair that specifies the following:

- When `-stop_on` is set to `cell_pin` (the default), the fanout walk traverses nets and design pins but stops on pins of cells or primitives in the fanout of the object. The walk may still, however, stop on a net or a design pin when the net or design pin does not have a fanout.
- When `-stop_on` is set to `net`, the fanout walk traverses through one level of “assign” statements and stops on the net connected to the start pin.
- When `-stop_on` is set to `pin`, the fanout walk traverses nets and reports the pin in the fanout of the object. This could be output or inout pins above the object or inputs or inout pins on child instances. The walk may still, however, stop on a net if the net does not fanout to pins.

- `-silent`

An optional switch that suppresses the error that is normally generated if any object within `obj_spec` does not exist, in which case it is ignored.

Examples

Example 1

The following example shows a series of `get_fanouts` command invocations of the circuit example shown in [Figure 4-5](#).

```
#Find cell pins in the fanout of u4/I5  
get_fanouts u4/I5
```

```
{u4/u4/A2 u4/u5/u3/D}
```

```
#Find pins in the fanout of u4/u1/Y. Returns a cell pin as there is no design pin before it  
get_fanouts u4/u1/Y -stop_on pin
```

```
{u4/u2/D}
```

```
#Find pins in the fanout of u4/u4/Y  
get_fanouts u4/u4/Y -stop_on pin
```

```
{u4/u1/A2 u4/u5/I2}
```

```
#Find all nets connected to the Q pin of dff modules  
get_fanouts [get_pins -filter {module_name == "dff"&& leaf_name == "Q"}] -stop_on net
```

```
{n2 O3 u4/n3 u4/O1 u4/u5/O1 u4/u5/O2 u5/n2}
```

```
#Find net in fanout of a cell output pin  
get_fanouts u1/Y -stop_on net
```

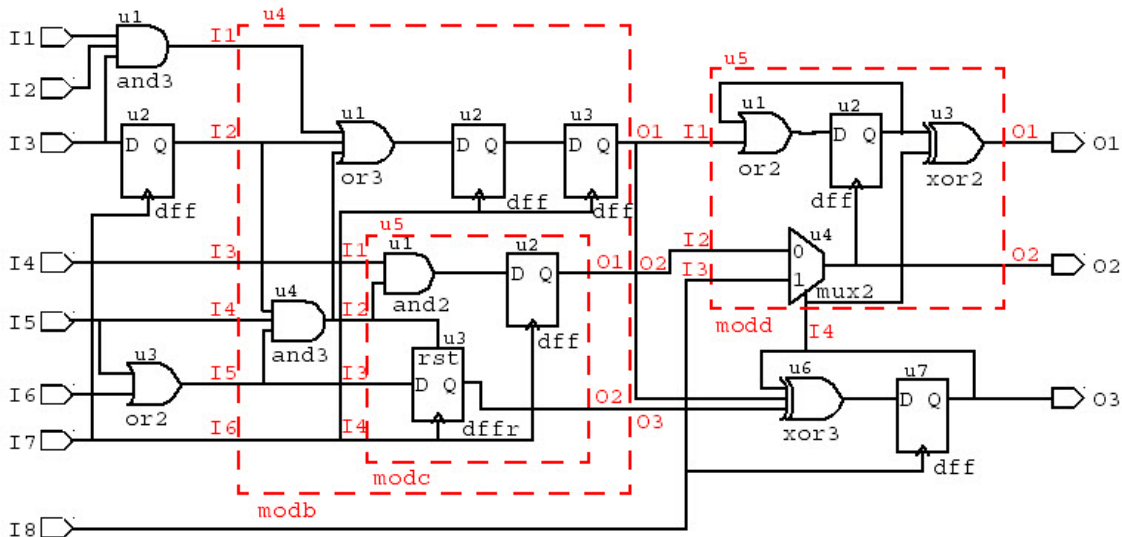

```
{n1}
```

Example 2

The following example adds an internal primary output (pseudo_port). Based on the example circuit shown in Figure 4-5, it then returns the collection of objects found in the fanout of the pseudo_port's underlying pin.

```
add_primary_outputs {u4/I5} -internal  
get_fanouts [get_ports u4/I5 -of_type pseudo]  
  
{u4/u4/A2 u4/u5/u3/D}
```

get_fault_type

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: all modes

Returns the current fault model type, as previously specified by the `set_fault_type` command.

Usage

```
get_fault_type
```

Description

Returns the current fault model type, as previously specified by the `set_fault_type` command.

The command returns one of the following strings: stuck, toggle, iddq, transition, path_delay, bridge, udfm.

Arguments

None

Examples

Example 1

The following example shows how to set the fault model type and then introspect the fault model:

```
ANALYSIS> set_fault_type bridge
ANALYSIS> get_fault_type
```

```
bridge
```

Example 2

The following example loads an SDC file if the current fault model type is “transition”:

```
if {[get_fault_type] eq "transition" } {
  read_sdc myDesign.sdc
} else {
  puts "No SDC file read. Fault type is [get_fault_type]."
}
```

Related Topics

[set_fault_type](#)

get_gate_pins

Context: all contexts

Mode: setup, analysis

Prerequisites: Although you can use this command in all system modes, you can only use it with a flattened netlist. In Tessent Shell, netlist flattening typically happens when you first attempt to enter analysis mode or when you issue the [create_flat_model](#) command.

Returns a collection of `gate_pin` objects found below the current design in the flat model.

Usage

```
get_gate_pins [gate_pin_id_list | hier_pin_name_patterns]  
  [-filter attribute_equation]  
  [-regex]  
  [-nocase]  
  [-silent]  
  [-of_instances instance_objects  
  | -below_instances instance_objects  
  | -of_pins pin_objects  
  | -of_ports port_objects  
  | -of_nets net_objects  
  | -of_gates {gate_id_list | gate_pin_objects | -from_objects from_objects}]  
  [-of_gate_type {sequential | primitive_name_list}
```

Description

Returns a collection of `gate_pin` objects found below the current design in the flat model.

The command supports arbitrary filtering based on attribute values. It also supports those options for frequently used filters.

Arguments

- *gate_pin_id_list* | *hier_pin_name_patterns*

An optional string that specifies a list of `gate_pin` objects. The *gate_pin_id_list* is a list of `gate_pin` IDs (two integers separated by a period, the first integer representing a gate and the second representing a `gate_pin`). No wildcards are permitted in the *gate_pin_id_list*. If the second integer is not present, the ID specifies all pins on the gate.

The *hier_pin_name_patterns* is a list of strings (wildcard patterns or regular expressions) matching hierarchical pin names. Using the *hier_pin_name_patterns* is equivalent to filtering on the `hier_pin_name` attribute.

Note

 When the `get_gate_pins` command operates on the flat model, it removes all backslashes and white spaces from escaped identifiers. You must not include backslashes or white spaces in the `hier_pin_name_patterns` string. If you want to access the corresponding `gate_pin`, use the `gate_pin_id` attribute of the hierarchical pin object. If you want to access the `gate_pin` by name, use the `get_name_list -remove_escaping` command and switch.

- `-filter attribute_equation`

An optional switch and string that specify to filter results based on the expression specified by the `attribute_equation` string. The attributes used within the equation must exist for the `gate_pin` object type. See “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The `=~` and `!~` matching operators used simple wildcard matching versus Posix extended regular expression based on the presence of the `-regexp` option or not.

- `-regexp`

An optional switch that directs the tool to interpret the value of the `hier_pin_name_patterns` argument as a regular expression instead of as a simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.

- `-nocase`

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for `gate_pins` matching the value of the `hier_pin_name_patterns` argument.

- `-silent`

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the `hier_pin_name_patterns` disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options -change_no_result_warnings_to_errors` switch description for detailed usage.

- `-of_instances instance_objects`

An optional switch and value pair that constrains the command to return only `gate_pins` associated with the specified `instance_objects`.

get_gate_pins

- `-below_instances instance_objects`

An optional switch and value pair that constrains the command to return only `gate_pins` associated with the circuitry located underneath the specified *instance_objects*.

If the specified *instance_spec* is an empty collection, all instances below the current design are considered. See the description of the [-below_instances switch](#) of the `get_instances` command description for the justification of this behavior.

- `-of_pins pin_objects`

An optional switch and value pair that constrains the command to return only `gate_pins` associated with the specified *pin_objects*.

- `-of_ports port_objects`

An optional switch and value pair that constrains the command to return only `gate_pins` associated with the specified *port_objects* or *pseudo_port* objects.

- `-of_nets net_objects`

An optional switch and value pair that constrains the command to return only `gate_pins` associated with the specified *net_objects*. If a `gate_pin` name directly matches the net name, the matching `gate_pin` is returned; otherwise, the driving `gate_pin` object of the net is returned.

- `-of_gates {gate_id_list | gate_pin_objects}`

An optional switch and value pair that constrains the command to return only `gate_pins` associated with the specified gates. The specified gates can be a list of gate IDs, `gate_pin` IDs, `gate_pin` objects or hierarchical pin name patterns.

- `-from_objects from_objects`

An optional switch and value pair that constrains the command to return only objects specified with the *from_objects* parameter, which may contain ports, *pseudo_ports*, pins, nets, and `gate_pins`. A port, *pseudo_port*, pin or net is mapped to the corresponding `gate_pins` in the same way the existing `-of_ports`, `-of_pins` or `-of_nets` options do. A `gate_pin` is just passed through to the result collection. This new option is convenient if you have a collection of design objects of different types that you want to map to `gate_pins`.

- `-of_gate_type {sequential | primitive_name_list}`

An optional switch and value pair that constrains the command to return only `gate_pins` associated with the gates of the specified types.

When the gate type *sequential* is specified, the command returns all the `gate_pin` objects associated with the gates whose `primitive_name` attribute value is DFF, DLAT, RAM, or ROM. The permitted values for the *primitive_name_list* are all the `primitive_name` attribute values (see [Table 8-6](#), Built-In Primitives and Primitive Port Names). The value of *primitive_name_list* can be either a single string or a Tcl list of strings such as `{PI PO}`.

Examples

Example 1

The following example filters the collection of all `gate_pin` objects based on an `attribute_equation` of user-defined attributes:

```
get_gate_pins -filter {myType1 || myType2 == "ABC"}  
{/u1/U2/b 16.0 16.1 16.2 24.0}
```

Example 2

The following example returns the collection of all `gate_pin` objects matching a list of case-insensitive hierarchical pin name patterns. For more examples of pattern matching with regular expressions, refer to “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638.

```
get_gate_pins {u1/u1/a u*/b} -nocase  
{/u1/U1/a /u1/U1/b /u1/U2/b /u1/U3/b /u2/U1/b}
```

Example 3

The following example returns a collection of all `gate_pin` objects on the gate with ID=12, the output `gate_pin` object (`pin_index=0`) on the gate with ID=14, and the `gate_pin` object with `pin_index=2` on the gate with ID=11:

```
get_gate_pins { 12 14.0 11.2 }  
{/u2/U1/b 12.0 14.0 /u1/U3/c}
```

Example 4

The following equivalent `get_gate_pins` commands return a collection of all `gate_pin` objects where the corresponding hierarchical pin name matches the wildcard pattern `/u1/*/a` or `/u2/U1*`:

```
get_gate_pins { /u1/*/a /u2/U1* }  
{/u1/U1/a /u1/U2/a /u1/U3/a /u2/U1/b /u2/U1/c /u2/U1/a /u2/U1/y /u2/U1/z}  
get_gate_pins -filter "hier_pin_name =~ /u1/*/a || hier_pin_name =~ /u2/U1*"  
{/u1/U1/a /u1/U2/a /u1/U3/a /u2/U1/b /u2/U1/c /u2/U1/a /u2/U1/y /u2/U1/z}
```

Example 5

The following example adds to the fault list all of the `gate_pin` objects corresponding to the hierarchical pins matching the wildcard pattern `u1/*`:

```
add_faults [get_gate_pins u1/*]  
report_faults
```

get_gate_pins

type	code	pin_pathname
0	UC	/u2/U1/b
1	UC	/u2/U1/b
0	UC	/u2/U1/c
1	UC	/u2/U1/c
0	UC	/u2/U1/a
1	UC	/u2/U1/a
0	UC	/u2/U1/y
1	UC	/u2/U1/y
0	UC	/u2/U1/z
1	UC	/u2/U1/z

Example 6

The following examples are based on the circuit in [Figure 4-4](#) on [page 953](#). This example returns all of the gate pins for the specified instance u4/u2:

```
SETUP> get_gate_pins -of_instances u4/u2
{u4/u2/Q u4/u2/QB u4/u2/CLK u4/u2/D}
```

This example returns all of the gate pins named D that are found below the u4 level of hierarchy:

```
SETUP> get_gate_pins */D -below_instances u4
{u4/u2/D u4/u3/D u4/u5/u2/D u4/u5/u3/D}
```

Example 7

The following examples return all the gate pins in gates of type DFF:

```
get_gate_pins -filter "primitive_name == DFF"
{7.0 7.1 7.2 DFF/CLK DFF/D}
```

```
get_gate_pins -of_gate_type DFF
{7.0 7.1 7.2 DFF/CLK DFF/D}
```

This example returns gate pins named D in all gates of type DFF:

```
get_gate_pins -of_gate_type DFF -filter "primitive_port_name == D"
{DFF/D}
```

get_icl_extraction_options

Context: all contexts

Mode: all modes

Provides access to the settings specified by the `set_icl_extraction_options` command.

Usage

```
get_icl_extraction_options  
    -extract_learned_muxes | -extract_library_muxes | -extract_scan_interfaces
```

Description

Provides access to the settings specified by the [set_icl_extraction_options](#) command.

Arguments

- `-extract_learned_muxes`
A switch that instructs the tool to return the `extract_learned_muxes` setting of the ICL extraction options. Possible values are 0 and 1.
- `-extract_library_muxes`
A switch that instructs the tool to return the `extract_library_muxes` setting of the ICL extraction options. Possible values are 0 and 1.
- `-extract_scan_interfaces`
A switch that instructs the tool to return the `extract_scan_interfaces` setting of the ICL extraction options. Possible values are 0 and 1.

Examples

The following command returns the setting specified by the `-extract_library_muxes` option of `set_icl_extraction_options` command:

```
get_icl_extraction_options -extract_library_muxes  
1
```

get_icl_fanins

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Returns a collection of ICL objects found in the fan-in of the specified ICL objects.

Usage

```
get_icl_fanins object_spec [{-stop_on none | pin} | -scan_path] [-silent]
```

Description

Returns a collection of ICL objects found in the fan-in of the specified ICL objects.

The allowed types of the objects in the *object_spec* and the types of the objects in the result collection depend on the usage of the `-scan_path` switch. If this switch is omitted, the only possible object types in the *object_spec* and in the result collection are `icl_port` and `icl_pin`. If the `-scan_path` switch is used, the possible object types in the *object_spec* and in the result collection are `icl_port`, `icl_pin`, `icl_scan_mux`, `icl_scan_register` and `icl_one_hot_scan_group`. The `-stop_on` option is used to specify if the command should look for the furthest objects in the fan-in or for the closest ones. Use “none” in the former case and “pin” in the latter case. `-stop_on` and `-scan_path` are mutually exclusive.

Arguments

- *object_spec*
A required value that specifies a single name, a list, or a collection of ICL objects, the fan-in of which will be analyzed. The allowed types of the objects in the *object_spec* depend on the usage of the `-scan_path` switch, as discussed in the description earlier in this topic.
- `-stop_on none | pin`
An optional switch and literal pair that specifies the following:
 - `none` — The fan-in walk traverses the connections and the ICL pins in the fan-in of the object. The trace reports `icl_pin` objects with no fan-in, `icl_pin` objects without any `icl_pin` or `icl_port` objects in their fan-in, or `icl_port` objects reached in the fan-in walk. This is the default.
 - `pin` — The fan-in walk traverses the connection and reports the `icl_pin` and `icl_port` objects in the fan-in of the object; this could be an ICL input pin above the object or an ICL output pin on a child ICL instance. The walk may still, however, stop on an ICL port if the ICL pin does not fan-in to ICL pins.
- `-scan_path`
An optional switch that limits the scope of the tracing to scan paths but also allows the usage of all object types of elements that can be encountered on a scan path: `icl_port`, `icl_pin`, `icl_scan_mux`, `icl_scan_register` and `icl_one_hot_scan_group`. When this switch is used, the *object_spec* as well as the returned collection can contain objects of these object types. The

tracing always stops immediately at the next encountered element. Tracing backwards from a ScanMux considers the scan data inputs only, but not the select inputs. Tracing backwards from a ScanOutPort considers the Source specification only, but not the Enable specification. Tracing backwards from a ScanRegister considers the ScanInSource specification only, but not the CaptureSource specification.

- **-silent**

An optional switch that suppresses the error that is normally generated if any object within `object_spec` does not exist.

Examples

The following example shows command invocations with and without the `-stop_on` pin option to illustrate its effect.

```
# find true fan-in of pin block1.sib1.si

get_icl_fanins block1.sib1.si

{si}

# Went through block1.si as -stop_on was defaulted to none.
# Reached ICL port si on the current_design find first pin in fan-in of
# block1.sib1.si

get_icl_fanins block1.sib1.si -stop_on pin

{block1.si}

# Stopped on block1.si as -stop_on was specified as pin.
```

[get_icl_fanouts](#)

[get_icl_fanins_in_module](#)

[get_icl_fanouts_in_module](#)

get_icl_fanins_in_module

Context: all contexts

Mode: all modes

Prerequisites: The ICL module that contains the specified objects must be elaborated.

Returns a collection of objects found in the fan-in of the specified icl_pin_in_module or icl_port objects.

Usage

```
get_icl_fanins_in_module obj_spec [-silent]
```

Description

Returns a collection of all icl_pin_in_module and icl_port objects found in the fan-in of the specified icl_pin_in_module or icl_port objects.

While the command [get_icl_fanins](#) can only be used when the current design is set, the command `get_icl_fanins_in_module` can be used without a current design being present. There is only one prerequisite: the ICL module containing the elements in the *obj_spec* must be elaborated. This can be achieved by means of the command [elaborate_icl_modules](#).

Arguments

- *obj_spec*
A required value that specifies a collection of one or more icl_pin_in_module or icl_port objects.
- -silent
An optional switch that suppresses all warnings and all error messages associated with the command. If the -silent switch is used, the command returns an empty collection instead of issuing an error in situations that would normally result in an error.

Examples

```
elaborate_icl_module chip  
set top_tdo [get_icl_ports tdo -of_module chip]  
{tdo}  
get_icl_fanins_in_module $top_tdo  
{tap_I1.tdo}  
set tap_tdi [get_icl_objects tap_I1.tdi -object_type icl_pin_in_module -in_module chip]  
{tap_I1.tdi}  
  
get_icl_fanins_in_module $tap_tdi
```

{tdi}

Related Topics

[elaborate_icl_modules](#)

[get_icl_fanins](#)

[get_icl_fanouts](#)

[get_icl_objects](#)

[get_icl_fanouts_in_module](#)

get_icl_fanouts

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Returns a collection of ICL objects found in the fanout of the specified ICL objects.

Usage

```
get_icl_fanouts object_spec [{-stop_on none | pin} | -scan_path] [-silent]
```

Description

Returns a collection of ICL objects found in the fanout of the specified ICL objects.

The allowed types of the objects in the *object_spec* and the types of the objects in the result collection depend on the usage of the `-scan_path` switch. If this switch is omitted, the only possible object types in the *object_spec* and in the result collection are `icl_port` and `icl_pin`. If the `-scan_path` switch is used, the possible object types in the *object_spec* and in the result collection are `icl_port`, `icl_pin`, `icl_scan_mux`, `icl_scan_register`, and `icl_one_hot_scan_group`. The `-stop_on` option is used to specify if the command should look for the furthest objects in the fanout or for the closest ones. Use “none” in the former case and “pin” in the latter case. `-stop_on` and `-scan_path` are mutually exclusive.

Arguments

- *object_spec*

A required value that specifies a single name, a list, or a collection of ICL objects, the fanout of which will be analyzed. The allowed types of the objects in the *object_spec* depend on the usage of the `-scan_path` switch, as discussed in the description earlier in this topic.

- `-stop_on none | pin`

An optional switch and literal pair that specifies the following:

`none` — The fanout walk traverses the connections and the ICL pins in the fanout of the object. The trace reports `icl_pin` objects with no fanout, `icl_pin` objects without any `icl_pin` or `icl_port` objects in their fanout, or `icl_port` objects that were reached in the fanout walk. This is the default.

`pin` — The fanout walk traverses the connection and reports the `icl_pin` and `icl_port` objects in the fanout of the object. This could be an ICL output pin above the object or an ICL input pin on child ICL instances. The walk may still, however, stop on an ICL port if the ICL pin does not fanout to ICL pins.

- `-scan_path`

An optional switch that limits the scope of the tracing to scan paths, but also allows the usage of all object types of elements that can be encountered on a scan path: `icl_port`, `icl_pin`, `icl_scan_mux`, `icl_scan_register` and `icl_one_hot_scan_group`. When this switch is used, the *object_spec* as well as the returned collection can contain objects of the

aforementioned object types. The tracing always stops immediately at the next encountered element. Tracing forward from a ScanRegister considers the path from the rightmost bit to another element on the scan path only, but not the parallel outputs of the update stage.

- **-silent**

An optional switch that suppresses the error that is normally generated if any object within `object_spec` does not exist..

Examples

The following example shows the `get_icl_fanouts` command invocations with and without the `-stop_on pin` option to illustrate its effect.

```
# find true fanout of pin block1.sib1.so
```

```
get_icl_fanouts block1.sib1.so
```

```
{so}
```

```
# Went through block1.so as -stop_on was defaulted to none. Reached ICL  
# port so on the current_design find first pin in fanout of block1.sib1.so
```

```
get_icl_fanouts block1.sib1.so -stop_on pin
```

```
{block1.so}
```

```
# Stopped on block1.so as -stop_on was specified as pin.
```

get_icl_fanouts_in_module

Context: all contexts

Mode: all modes

Prerequisites: The ICL module that contains the specified objects must be elaborated.

Returns a collection of objects found in the fanout of the specified `icl_pin_in_module` or `icl_port` objects.

Usage

```
get_icl_fanouts_in_module obj_spec [-silent]
```

Description

Returns a collection of all `icl_pin_in_module` and `icl_port` objects found in the fanout of the specified `icl_pin_in_module` or `icl_port` objects.

While the command [get_icl_fanouts](#) can only be used when the current design is set, the command `get_icl_fanouts_in_module` can be used without a current design being present. There is only one prerequisite: the ICL module containing the elements in the *obj_spec* must be elaborated. This can be achieved by means of the command [elaborate_icl_modules](#).

Arguments

- *obj_spec*
A required value that specifies a collection of one or more `icl_pin_in_module` or `icl_port` objects.
- `-silent`
An optional switch that suppresses all warnings and all error messages associated with the command. If the `-silent` switch is used, the command returns an empty collection instead of issuing an error in situations that would normally result in an error.

Examples

```
elaborate_icl_module chip  
set top_tdi [get_icl_ports tdi -of_module chip]  
{tdi}  
get_icl_fanouts_in_module $top_tdi  
{sib_I1.si tap_I1.tdi block1_I1.si}  
set tap_tdo [get_icl_objects tap_I1.tdo -object_type icl_pin_in_module -in_module chip]  
{tap_I1.tdo}  
  
get_icl_fanouts_in_module $tap_tdo
```

get_icl_instances

Context: all contexts

Mode: all modes

Returns a collection of all ICL instances instantiated relative to the current design that match the specified *<*name_patterns>* list or -filter expression.

Usage

Usage 1: Without the -hierarchical option

```
get_icl_instances [name_patterns] [-of_modules icl_module_objects]
  [-parent_of_instances instance_objects | -below_instances instance_objects |
  -of_pins icl_pin_objects | -of_instances design_instance_objects]
  [-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Usage 2: With the -hierarchical option

```
get_icl_instances [leaf_name_patterns] [-of_modules icl_module_objects]
  [-parent_of_instances instance_objects | -below_instances instance_objects]
  [-hierarchical] [-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Usage 3: With no name pattern

```
get_icl_instances [-of_modules icl_module_objects]
  [-parent_of_instances instance_objects | -below_instances instance_objects |
  -of_pins icl_pin_objects]
  [-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Description

Returns a collection of all ICL instances instantiated relative to the current design that match the specified *<*name_patterns>* list or -filter expression.

- **Usage 1** — The name patterns are expressed as hierarchical instance path names relative to the current design. You can have any number of wildcards or regular expressions in the names between the hierarchy separator symbols as shown in the examples for this command. You can use the dot or the slash as the hierarchy separator when not using the -regexp option. You can only use the slash as the hierarchy separator when using the -regexp option because the dot is the wildcard symbol when using regular expressions.
- **Usage 2** — The name patterns are leaf instance names with any number of wildcards or regular expressions. Unlike in Usage 1, the leaf instance name pattern is searched relative to all ICL instances found below the current design.
- **Usage 3** — A name_patterns argument is not specified so that all ICL instances are selected and then filtered by the other criteria specified by the other optional arguments.

If you issue this command but have not previously loaded any icl files, it returns an empty collection.

Arguments

- *name_patterns*

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of ICL instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no *name_patterns* are specified, the tool searches all ICL instances that match the results returned by the `-filter` attribute_equality filter as shown in Usage 3. In Usage 2, described previously, the name patterns cannot include slashes or dots, which are hierarchy separator symbols. In Usage 1, you can use the dot or slash as the hierarchy separator when not using the `-regex` option. You can only use the slash as the hierarchy separator when using the `-regex` option because the dot is the wildcard symbol when using regular expressions.

- `-of_modules` *icl_module_objects*

An optional switch and value pair that constrains the command to return only instances of ICL modules specified by *icl_module_objects*. The *icl_module_objects* is a Tcl list of one or more ICL module names, or a collection of one or more ICL module objects as returned by the [get_icl_modules](#) command.

- `-parent_of_instances` *instance_objects*

An optional switch and value pair that constrains the command to return a collection of ICL instance objects that are the parent instances of the specified *instance_objects*. The returned collection is filtered to only return a given parent instance once. When this option is specified, the optional *name_patterns* option is a string that is matched against the leaf instance name of every parent instance of the collection. An error is generated if the specified *name_patterns* contain more than one level of hierarchy when the `-parent_of_instances` option is used.

- `-below_instances` *instance_objects*

An optional switch and value pair that constrains the command to search for ICL instances below the specified *instance_objects*. The specified *name_patterns* are searched relative to each instance found in the *instance_objects* list.

If the specified *instance_spec* is an empty collection, all instances below the current design are considered. See the description of the [-below_instances](#) switch of the [get_instances](#) command description for the justification of this behavior.

- `-of_pins` *icl_pin_objects*

An optional switch and value pair that constrains the command to return the ICL instance to which the ICL pins belong. The returned collection is filtered to return any given ICL instance only once, even if the instance belongs to many ICL pins in the *icl_pin_objects* list. When this option is specified, the optional *name_patterns* must be leaf_name patterns that are checked against the leaf name of the ICL instances. An error is generated if the specified *name_patterns* contains more than one level of hierarchy when the `-of_pins` option is used.

- `-of_instances` *design_instance_objects*

An optional switch and value pair that constrains the command to return the ICL instances corresponding to the design instances specified by *design_instance_objects*. The *design_instance_objects* is a Tcl list of design instances or a collection of one or more design instances as returned by the `get_instances` command.

- `-hierarchical`

An optional string that specifies to perform pattern matching relative to all ICL instances found below the current design. When you specify this option, the `name_patterns` argument cannot include slashes or dots, which are hierarchy separator symbols.

- `-filter` *attribute_equation*

An optional switch and string pair that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the ICL instance object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on the filtering attribute equation format.

- `-regexp`

An optional switch that directs the tool to interpret the value of the `name_patterns` argument and the arguments of the `=~` and `!~` `-filter` expressions as regular expressions instead of as simple wildcard patterns. You must properly escape the bracket “[]” symbols so that they are interpreted as part of the regular expression and not interpreted by the Tcl shell. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax. You must use the slash as a hierarchy separator when using the `-regexp` option.

- `-nocase`

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for instances matching the `name_patterns`.

- `-silent`

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options` [-change_no_result_warnings_to_errors](#) switch description for detailed usage.

Examples

Example 1

The following example illustrates Usage 3 and returns the collection of all instances of ICL modules modb and modd found anywhere below the current design:

```
get_icl_instances -of_modules {modb modd}  
{u2 u1/u5}
```

Example 2

The following example illustrates Usage 3 in which the collection of all instances is filtered based on an attribute_equality of user-defined attributes.

```
get_icl_instances -filter {myType1 || myType2 == "ABC"}  
{u2 u1.u5}
```

Example 3

The following example illustrates Usage 1 in which the collection of all instances matching a list of hierarchical name patterns is returned. The names u1/* and u*/u* are only searched relative to the current design.

```
get_icl_instances {u1/* u*/u*}  
{u4.u5 u1.u7}
```

Example 4

The following example illustrates Usage 2 in which the collection of all instances matching a leaf name pattern is returned. The leaf instance name u3* searches for all instances found below the current design.

```
get_icl_instances u3* -hierarchical  
{u3 u4.u30 u4.u5.u31 u5.u3}
```

Example 5

The following example shows how to use the -filter switch in Usage 3, with the search criteria specified by the optional introspection commands, tessent_instrument_type, and tessent_instrument_subtype.

```
get_icl_instances
```

get_icl_instances

```

[get_icl_modules](#)

[get_icl_ports](#)

[read_icl](#)

get_icl_modules

Context: all contexts

Mode: all modes

Returns a collection of all ICL modules that match the specified `name_patterns` list or `-filter` expression.

Usage

```
get_icl_modules [name_patterns] [-of_instances instance_objects |  
-below_instances instance_objects | -of_modules design_module_objects |  
-parameterized_views_of_modules icl_module_objects]  
[-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Description

Returns a collection of all ICL modules that match the specified `name_patterns` list or `-filter` expression.

By default, this command returns all ICL modules below the current design. You can use the `-of_instances` argument to constrain the search.

You can have any number of wildcards or regular expressions in the name patterns.

If you issue this command but have not previously loaded any icl files, it returns an empty collection.

Arguments

- *name_patterns*
An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of ICL modules. If no `name_patterns` are specified, the tool searches all ICL modules that match the results returned by the `-filter attribute_equation` filter.
- `-of_instances` *instance_objects*
An optional switch and value pair that constrains the command to return only ICL modules of the specified *instance_objects*. The `instance_objects` is a Tcl list of one or more ICL instance names, or a collection of one or more ICL instance objects as returned by the `get_icl_instances` command. You could use the `module_name` attribute of the instance objects to perform a similar filtering but this method is more direct and efficient.
- `-below_instances` *instance_objects*
An optional switch and value pair that constrains the command to return only ICL modules corresponding to instances found below the specified *instance_objects*.

If the specified *instance_spec* is an empty collection, all instances below the current design are considered. See the description of the `-below_instances` switch of the `get_instances` command description for the justification of this behavior.

- `-of_modules` *design_module_objects*

An optional switch and value pair that constrains the command to return a collection of ICL modules corresponding to the design modules specified by *design_module_objects*. The *design_module_objects* is a Tcl list of one or more design modules, or a collection of one or more design modules as returned by the `get_modules` command.

- `-parameterized_views_of_modules` *icl_module_objects*

An optional switch and value pair that constrains the command to return a collection of ICL modules corresponding to all the parameterized views of the ICL module objects specified. The *icl_module_objects* can be specified as a Tcl list of ICL module names or a collection of ICL modules. Whether *icl_module_objects* contains a parameterized view or the primary copy of an ICL module, this switch instructs the command to find all parameterized views and return them. Using this switch is equivalent to using the `master_name` attribute of an ICL module and requesting all ICL modules having the same `master_name` value. Using this switch, however, is more efficient. You use this switch to determine whether an ICL module is uniquely instantiated or not and to find out if an ICL module has multiple parameterized views.

- `-filter` *attribute_equation*

An optional switch and string pair that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the ICL module object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The `=~` and `!~` matching operator use simple wildcard matching versus Posix extended regular expression based on the presence of the `-regexp` option.

- `-regexp`

An optional switch that directs the tool to interpret the value of the `name_patterns` argument and the arguments of the `=~` and `!~` `-filter` expressions as regular expressions instead of as simple wildcard patterns. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.

- `-nocase`

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for modules matching the `name_patterns`.

- `-silent`

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options -change_no_result_warnings_to_errors` switch description for detailed usage.

Examples

Example 1

The following example returns ICL modules whose name matches `a*` or `b*`.

```
get_icl_modules {a* b*}  
{ab abc b bcd}
```

Example 2

The following example returns ICL modules having one or two characters.

```
get_icl_modules {[:alnum:]{1,2}} -regexp  
{ab b}
```

Example 3

This example shows how to report the names of the parameterized views for a module.

```
puts "[get_name_list [get_icl_modules -parameterized_views_of_modules block]]"  
block block@PV1 block@PV2
```

Related Topics

[get_icl_instances](#)

[get_icl_ports](#)

[read_icl](#)

get_icl_module_parameter_list

Context: all contexts

Mode: all modes

Returns the list of parameters in an ICL module.

Usage

```
get_icl_module_parameter_list module_object [-overridden]
```

Description

Returns the list of parameters in an ICL module.

Arguments

- *module_object*
A required string that specifies the parameterized ICL module objects whose parameters are to be returned.
- -overridden
An optional switch that specifies to only list those parameters whose default values are overridden during an instantiation.

Return Values

List of parameters.

Examples

In the following example, this command is used to obtain the list of parameters overridden in the specific instantiation. Note how the [get_icl_instances](#) command is used to find the ICL instance *u1/myinst_i1*; this ensures that the [get_attribute_value_list](#) command returns the `module_name` attribute of the ICL instance and not the design instance in case a design instance of the same name exists.

```
set icl_inst [get_icl_instance u1/myinst_i1]

set params [get_icl_module_parameter_list [get_attribute_value_list $icl_inst \
-name module_name] -overridden]
```

Related Topics

[get_icl_module_parameter_value](#)

get_icl_module_parameter_value

Context: all contexts

Mode: all modes

Returns the value of the parameter on the specified module and indicates whether it is the default value or is overridden.

Usage

`get_icl_module_parameter_value parameter_name [-of_module icl_module_object]`

Description

Returns the value of the parameter on the specified module and indicates whether it is the default value or is overridden.

Arguments

- *parameter_name*
A required string that specifies the name of the parameter whose value is to be returned.
- `-of_module icl_module_object`
An optional switch and string pair that specifies the ICL module whose parameter value is to be returned. When omitted, the parameters of the current design are introspected.

Return Values

The value of the requested ICL module parameter.

Examples

In the following example, the values of all overridden parameters are echoed in the transcript. Note how the [get_icl_instances](#) command is used to find the ICL instance `u1/myinst_i1`; this ensures that the [get_attribute_value_list](#) command returns the `module_name` attribute of the ICL instance and not the design instance in case a design instance of the same name exists.

```
set icl_inst [get_icl_instance u1/myinst_i1]

set icl_mod [get_attribute_value_list $icl_inst -name module_name]

set params [get_icl_module_parameter_list $icl_mod -overridden]

foreach param $params {
  puts "parameter $param = [get_icl_module_parameter_value $param \
    -of_mod $icl_mod]"
}
```

Related Topics

[get_icl_module_parameter_list](#)

get_icl_network

Context: patterns -silicon_insight -ijtag

Mode: setup

Returns various values for the specified option.

Usage

```
get_icl_network { node_name {-node_type | -inputs | -outputs | -current_input_index } |
  -current_scan_path_length | -is_current_scan_path_testable | -current_scan_path_nodes |
  -nodes_of_type node_type | -nodes_of_status diagnosis_status }
```

Description

The command has two major forms: retrieving information about a given node or retrieving general ICL network-related data.

Use this command when manually debugging IJTAG networks as described in “[Diagnosing and Debugging IJTAG Networks](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

Arguments

- *node_name* {-node_type | -inputs | -outputs | -current_input_index }
An optional variable and literal pair that returns information about the specified node.
Options are:
 - node_type — The node type: port, SIB, scan mux, or scan register.
 - inputs — Input nodes for the specified node.
 - outputs — Output nodes for the given node.
 - current_input_index — Input index for the currently active scan path.
- -current_scan_path_length
An optional switch that returns the length of the current scan path in terms of the number of flops from the input signals to the output signals.
- -is_current_scan_path_testable
An optional switch that returns true or false depending on whether the current scan path is testable or not. A scan path is deemed untestable if one or more elements in the scan path are untestable. A scan element may be untestable if the following attributes are set to on: `tessent_ignore_during_icl_verification` and `explicit_iwrite_only`.
- -current_scan_path_nodes
An optional switch that returns a list of scan element names in the current scan path from TDI to TDO.

- `-nodes_of_type node_type`
An optional switch and variable pair that returns the list of nodes of the specified type in the JTAG network.
- `-nodes_of_status diagnosis_status`
An optional switch and variable pair that returns a list of nodes of the specified diagnosis status, based on the last performed diagnosis. Options are:
 - suspect
 - bad
 - good
 - untested

Examples

get_icl_network -current_scan_path_nodes

```
tdo tap_I1.IRMux@0 tap_I1.DRMux@1 sib_I4@0 sib_I3@0 sib_I2@0 sib_I1@0 tdi
```

get_icl_objects

Context: all contexts

Mode: all modes

Returns a collection of ICL object matching the requested criteria.

Usage

```
get_icl_objects [name_patterns] -object_types object_types  
  [-below_instances icl_instance_spec | -parent_of_instances icl_instance_spec  
  | -in_modules icl_module_spec | -of_objects icl_object_specs]  
  [-hierarchical]  
  [-direction direction]  
  [-function function]  
  [-filter attribute_equation]  
  [-regexp]  
  [-nocase]  
  [-silent]
```

Description

This command combines the complete usage of [get_icl_modules](#), [get_icl_instances](#), [get_icl_ports](#), and [get_icl_pins](#) plus provides introspection into other ICL object types as well as the ability to see objects inside a module before it is elaborated. [Table 4-5](#) lists the available object types and against which object they can be requested from. The object types `icl_instance`, `icl_pin`, `icl_scan_interface`, `icl_scan_register`, `icl_scan_mux` and `icl_one_hot_scan_group` are only available when ICL is elaborated. You can get access to their `_of_module/` `_in_module` counterpart without requiring the ICL to be elaborated, but you are limited to the object directly declared in the ICL module. This difference is illustrated in [Example 2](#) below.

Arguments

- *name_patterns*
An optional Tcl list of one or more strings that specifies patterns to be used to filter the returned list of ICL object based on their name attributes. If no *name_patterns* are specified, the tool searches all ICL object that match the other criteria.
- **-object_types** *object_types*
A required Tcl list of one or more strings that specifies ICL object types to consider in the search. The tool supports the following ICL object types:
 - `icl_module`
 - `icl_port`
 - `icl_instance`
 - `icl_instance_in_module`

- icl_pin
 - icl_pin_in_module
 - icl_scan_interface
 - icl_scan_interface_of_module
 - icl_scan_register
 - icl_scan_register_in_module
 - icl_scan_mux
 - icl_scan_mux_in_module
 - icl_one_hot_scan_group
 - icl_one_hot_scan_group_in_module
 - icl_alias
 - icl_alias_in_module
 - icl_sib
- -below_instances *icl_instance_spec*

An optional switch-value pair used to specify a Tcl list of one or more names of icl_instance objects or a collection containing one or more icl_instance objects. This option can only be used when the -object_type switch specifies at least one of the following object types:

 - icl_instance
 - icl_pin
 - icl_scan_interface
 - icl_scan_register
 - icl_scan_mux
 - icl_one_hot_scan_group
 - icl_alias

If the specified *instance_spec* is an empty collection, all instances below the current design are considered. See the description of the [-below_instances switch](#) of the [get_instances](#) command description for the justification of this behavior
 - -parent_of_instances *icl_instance_spec*

An optional switch-value pair used to specify a Tcl list of one or more names of icl_instance objects or a collection containing one or more icl_instance objects. This option can only be used when the -object_type switch specifies “icl_instance”. When you specify this option, the optional *name_patterns* must be leaf_name patterns that are checked against the leaf

get_icl_objects

names of the ICL instances. The tool generates an error if the specified *name_patterns* contain more than one level of hierarchy when you use the `-parent_of_instances` option.

- `-in_modules` *icl_module_spec*

An optional switch-value pair used to specify a Tcl list of one or more names of ICL modules or a collection contain one or more ICL module objects. The permitted types in the `-object_types` switch value are “`icl_instance_in_module`”, “`icl_pin_in_module`”, “`icl_scan_register_in_module`”, “`icl_scan_mux_in_module`”, “`icl_one_hot_scan_group_in_module`” and “`icl_alias_in_module`” when the `-in_modules` switch is used.

- `-of_objects` *icl_object_spec*

An optional switch-value pair used to specify a Tcl list of one or more names of ICL objects or a collection containing one or more ICL objects. [Table 4-5](#) shows the permitted type for the *icl_object_spec* objects based on the `-object_types` requested.

icl_scan_register_in_module	icl_module
icl_sib	icl_sib

- **-hierarchical**

An optional string that specifies to perform pattern matching relative to all ICL instances found below the current design. The *name_patterns* argument cannot include more than one dot when the **-hierarchical** option is specified and the **-object_types** switch specifies one of the following: *icl_pin*, *icl_scan_interface*, *icl_scan_register*, *icl_scan_mux*, *icl_one_hot_scan_group*, *icl_alias* or *icl_sib*. The dot is the hierarchy separator symbols in ICL. When any other object type is specified the *name_patterns* argument must not contain any hierarchy separator.

- **-direction *direction***

An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the ICL pin or port objects. When this argument is omitted, pins or ports with any direction are considered.

- **-function *function_list***

An optional switch-value pair that specifies to filter results based on the value of the *ijtag_function* attribute on the ICL pin or port object. When this argument omitted, ports or pins with any *ijtag_function* value are considered. The *ijtag_function* values are the ICL port function as found in the ICL description, where multiple words are separated by underscores instead of using camel casing without the “_port” termination. For example, a port declared as a ScanInPort in ICL uses the function name *scan_in* in the ICL data model.

- *-filter attribute_equation*

An optional switch and string pair to filter results specified by the *attribute_equation* string. The *attribute_equation* string filters icl_object attributes reported by [report_attributes](#). The attributes used within the equation must exist for all the object types listed in the *-object_type* switch. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on the filtering attribute equation format. The `=~` and `!~` matching operators use simple wildcard matching versus Posix extended regular expression based on the *-regexp* option.

- *-regexp*

An optional switch that directs the tool to interpret the value of the *name_patterns* argument and the arguments of the `=~` and `!~` *-filter* expressions as regular expressions instead of as simple wildcard pattern.

- *-nocase*

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for ICL object names matching *name_patterns*.

- *-silent*

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This *-silent* option has no effect on any other error reporting.

Note

You can use the *-silent* switch to manage the case in which an empty collection is returned. Before using the *-silent* switch for this purpose, refer to the [set_tcl_shell_options -change_no_result_warnings_to_errors](#) switch description for detailed usage.

Examples

Example 1

The following example illustrate how you can query objects of multiple types using a single invocation of the `get_icl_objects` command. This cannot be done when using [get_icl_ports](#) and [get_icl_pins](#) command. The example usage queries for ICL ports and ICL pins with `ijtag_function` equal to `capture_en` within the elaborate ICL design.

```
get_icl_objects -object_type {icl_pin icl_port} -function capture_en
{corea_rtl1_tessent_mbist_bap_inst.capture_en
corea_rtl1_tessent_sib_mbist_inst.ijtag_ce
corea_rtl1_tessent_sib_sti_inst.ijtag_ce
corea_rtl2_tessent_edt_c1_tdr_inst.ijtag_ce
corea_rtl2_tessent_occ_child_clkb_inst.ijtag_ce
corea_rtl2_tessent_occ_child_clkb_inst.tdr_sib.capture_en
corea_rtl2_tessent_occ_child_nocg_clka_inst.ijtag_ce
corea_rtl2_tessent_occ_child_nocg_clka_inst.tdr_sib.capture_en
corea_rtl2_tessent_occ_child_nocg_clkc_inst.ijtag_ce
corea_rtl2_tessent_occ_child_nocg_clkc_inst.tdr_sib.capture_en
corea_rtl2_tessent_sib_edt_inst.ijtag_ce
corea_rtl2_tessent_sib_occ_inst.ijtag_ce
corea_rtl2_tessent_sib_sri_inst.ijtag_ce
corea_rtl2_tessent_tdr_sri_ctrl_inst.ijtag_ce ijtag_ce}
```

Example 2

The following example illustrates the difference between the object types ending with “_of_module” and those that do not. The `icl_scan_interface` object_type is a hierarchical object_type that exists in the current design and on ICL instances. Their names are the full hierarchical paths of their associated ICL instances followed by the leaf_name of the scan interface. They only exist when the ICL is elaborated. The `icl_scan_interface_of_module` object_type is a non-hierarchical object_type that exists on ICL modules. Their names are the leaf_name of the scan interface. They exist even if ICL is not elaborated. The top part of the example uses the hierarchical object types to find specific instances of an ICL scan interface and follows to extract the ICL pins with function `scan_in` from it. The second part of the example uses the non-hierarchical object types to find the ICL scan interface of a module and follow the interface to extract the ICL port with function `scan_in` from it. The second method is useful when you want to extract information about ICL modules and the top level ICL is not yet extracted and elaborated. It is also useful to introspect ICL modules not part of the current ICL elaboration tree.

This part shows introspecting the ICL pins of ICL scan interfaces when ICL is elaborated

```
set icl_scan_int [get_icl_objects -object_type icl_scan_interface \
  -of_objects [get_icl_instances corea_rtl2_tessent_sib_sri_inst]]
```

```
{corea_rtl2_tessent_sib_sri_inst.client
corea_rtl2_tessent_sib_sri_inst.host}
```

```
set icl_pins [get_icl_objects -object_type icl_pin \
  -of_object $icl_scan_int \
  -function scan_in]
```

```
{corea_rtl2_tessent_sib_sri_inst.ijtag_si
corea_rtl2_tessent_sib_sri_inst.ijtag_from_so}
```

This part shows introspecting the ICL pins of ICL scan interfaces when ICL is elaborated

```
set icl_scan_int [get_icl_objects -object_type icl_scan_interface \
  -of_objects [get_icl_instances corea_rtl2_tessent_sib_sri_inst]]
```

```
{corea_rtl2_tessent_sib_sri_inst.client
corea_rtl2_tessent_sib_sri_inst.host}
```

get_icl_objects

```
set icl_pins [get_icl_objects -object_type icl_pin \  
    -of_object $icl_scan_int \  
    -function scan_in]
```

```
{corea_rtl2_tessent_sib_sri_inst.ijtag_si  
corea_rtl2_tessent_sib_sri_inst.ijtag_from_so}
```

**# This part shows introspecting the ICL ports of ICL scan interfaces of ICL modules when
ICL is NOT elaborated**

```
set icl_scan_int_of_mod [get_icl_objects -object_type icl_scan_interface_of_module \  
    -of_objects [get_icl_modules corea_rtl2_tessent_sib_1]]
```

```
{client host}
```

```
set icl_port [get_icl_objects -object_type icl_port -of_objects $icl_scan_int_of_mod  
    -function scan_in]
```

```
{ijtag_si ijtag_from_so}
```

Related Topics

[get_common_parent_instance](#)

[get_icl_ports](#)

get_icl_pins

Context: all contexts

Mode: all modes

Returns a collection of all hierarchical ICL pins instantiated relative to the current design that match the specified *name_patterns* list or *-filter* expression.

Usage

Usage 1: Without the *-hierarchical* option

```
get_icl_pins name_patterns [-direction input | output] [-function function]  
  [-of_instances instance_objects | -below_instances instance_objects /  
  -of_pins design_pin_objects]  
  [-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Usage 2: With the *-hierarchical* option

```
get_icl_pins leaf_name_patterns | leaf_instance/leaf_name_patterns -hierarchical  
  [-below_instances instance_objects] [-filter attribute_equation]  
  [-direction input | output] [-function function]  
  [-regexp] [-nocase] [-silent]
```

Usage 3: With no name pattern

```
get_icl_pins [-filter attribute_equation] [-direction input | output] [-function function] [-regexp]  
  [-nocase] [-silent]
```

Description

Returns a collection of all hierarchical ICL pins instantiated relative to the current design that match the specified *name_patterns* list or *-filter* expression.

- **Usage 1** — The name patterns are expressed as hierarchical pin pathnames relative to the current design. You can have any number of wildcards or regular expressions in the names between the hierarchy separator symbols as shown in the examples that follow. You can use the dot or the slash as the hierarchy separator when not using the *-regexp* option. You can only use the slash as the hierarchy separator when using the *-regexp* option because the dot is the wildcard symbol when using regular expressions.
- **Usage 2** — The name patterns are leaf pin names or leaf instance name/leaf pin names with any number of wildcards or regular expressions. Unlike in Usage 1, the leaf name pattern is searched relative to all instances found below the current design. There can only be one hierarchy separator when using the *-hierarchical* option as shown in Example 3.
- **Usage 3** — A *name_patterns* argument is not specified so all ICL pins are selected and then filtered by the other criteria specified by the other optional arguments.

If you issue this command but have not previously loaded any icl files, it returns an empty collection.

Arguments

- *name_patterns* | *leaf_instance/leaf_name_patterns*

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of pins. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no *name_patterns* are specified, the tool searches all ICL pins that match the results returned by the *-filter attribute_equation* filter as shown in Usage 3. In Usage 2, described previously, the name patterns are not permitted to include more than one slash or dot, which are hierarchy separator symbols. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for a complete description of the pattern syntax when the *-regexp* option is used or not.

- *-direction* input | output

An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the pin object. When omitted, pins with any direction are considered.

- *-of_instances* *instance_objects*

An optional switch and value pair that constrains the command to return only ICL pins of the specified *instance_objects*. The *instance_objects* is a Tcl list of one or more ICL instance names, or a collection of one or more ICL instance objects as returned by the *get_icl_instances* command. You could use the *module_name* attribute of the instance objects to perform a similar filtering but this method is more direct and efficient.

- *-below_instances* *instance_objects*

An optional switch and value pair that constrains the command to search for ICL pins below the specified *instance_objects*. Specified *name_patterns* are searched relative to the specified *instance_objects* when this option is used.

If the specified *instance_objects* is an empty collection, all instances below the current design are considered. See the description of the *-below_instances* switch of the [get_instances](#) command description for the justification of this behavior.

- *-of_pins* *design_pin_objects*

An optional switch and value pair that constrains the command to return only ICL pins corresponding to the design pins specified by *design_pin_objects*. The *design_pin_objects* is a Tcl list of one or more design pins, or a collection of one or more design pins as returned by the *get_pins* command.

The *tessent_design_rtl_ports* and *tessent_design_gate_ports* attributes are used to retrieve the ICL pins from design pins. The *tessent_design_rtl_ports* attribute is used when in RTL mode and the current view is an RTL view. Otherwise, the *tessent_design_gate_ports* attribute is used.

To use this command in no RTL mode when the current view is a netlist view, the *tessent_design_gate_ports* attribute must be up to date. In most cases, this is true after the *set_current_design* command is invoked. For sub-blocks, it is only true after *write_design* or *update_icl_attributes_from_design* is invoked. See “[Post-Synthesis Update](#)” in the *Tessent Shell User’s Manual* for further information.

- **-hierarchical**
An optional string that specifies to perform pattern matching relative to all ICL instances found below the current design. When this option is specified, the *name_patterns* argument cannot include more than one slash or dot, which are the hierarchy separator symbols.
- **-function function**
An optional switch and literal pair that specifies to filter results based on the value of the function attribute on the ICL pin object. When omitted, pins with any function are considered. The value function is a Tcl list of function names derived from the ICL port function where multiple words are separated by underscores instead of using camel casing. For example, a port declared as a ScanInPort in ICL has function scan_in in the ICL data model.
- **-filter *attribute_equation***
An optional switch and string pair that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the ICL pin object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The =~ and !~ matching operators use simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option.
- **-regexp**
An optional switch that directs the tool to interpret the value of the *name_patterns* argument and the arguments of the =~ and !~ -filter expressions as regular expressions instead of as simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.
- **-nocase**
An optional switch that directs the tool to perform case-insensitive pattern matching when looking for ICL pin names matching *name_patterns*.
- **-silent**
An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This -silent option has no effect on any other error reporting.

Note

 You can use the -silent switch to manage the case in which an empty collection is returned. Before using the -silent switch for this purpose, refer to the set_tcl_shell_options [-change_no_result_warnings_to_errors](#) switch description for detailed usage.

Examples

Example 1

The following example illustrates Usage 3 where the collection of all ICL pins is filtered based on an attribute_equation of user-defined attributes.

```
get_icl_pins -filter {myType1 || myType2 == "ABC"}  
{u1.Y u4.u4.A0 u7.D}
```

Example 2

The following example illustrates Usage 1 where the collection of all ICL pins matching a list of hierarchical name patterns is returned. The names u1/Y and u*/Q are only searched relative to the current design. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for examples of pattern matching with regular expressions.

```
get_icl_pins {u1/Y u*/Q}  
{u1.Y u2.Q u7.Q}
```

Example 3

The following example illustrates Usage 2 where the collection of all ICL pins matching a leaf instance_name/leaf pin name pattern is returned. The tool searches for the leaf instance name u* in all ICL instances found below the current design, and then searches for the leaf pin names matching Y* on those instances.

```
get_icl_pins u*/Y* -hierarchical  
{u1.Y u3.Y u4.u1.Y u4.u4.Y u4.u5.u1.Y u5.u1.Y u5.u3.Y u5.u4.Y u6.Y}
```

Example 4

The following example gets all ICL pins with function clock or to_clock in the ICL data base.

```
get_icl_pins -function {clock to_clock}  
{PLL1.ref PLL1.vco mbist.clk}
```

[get_common_parent_instance](#)

[get_icl_ports](#)

[read_icl](#)

get_icl_ports

Context: all contexts

Mode: all modes

Returns a collection of all ICL ports that match the specified *name_patterns* list or *-filter* expression.

Usage

```
get_icl_ports [name_patterns] [-of_modules icl_module_objects |  
-of_ports design_port_objects] [-direction input | output]  
[-function function] [-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Description

Returns a collection of all ICL ports that match the specified *name_patterns* list or *-filter* expression.

You can have any number of wildcards or regular expressions in the name patterns.

If you issue this command but have not previously loaded any icl files, it returns an empty collection.

Arguments

- *name_patterns*
An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of ports. If no *name_patterns* are specified, the tool searches all ports that match the results returned by the *-filter attribute_equation* filter, if one is specified.
- *-of_modules icl_module_objects*
An optional switch and value pair that constrains the command to return only ICL ports on modules specified by *icl_module_objects*. The *icl_module_objects* is a Tcl list of ICL module names or a collection of one or more module objects as returned by the *get_icl_modules* command.
- *-of_ports design_port_objects*
An optional switch and value pair that constrains the command to return only ICL ports corresponding to the design ports specified by *design_port_objects*. The *design_port_objects* is a Tcl list of design ports or a collection of one or more design ports as returned by the *get_ports* command.

The *tessent_design_rtl_ports* and *tessent_design_gate_ports* attributes are used to retrieve the ICL ports from design ports. The *tessent_design_rtl_ports* attribute is used when in RTL mode and the current view is an RTL view. Otherwise, the *tessent_design_gate_ports* attribute is used.

To use this command in no RTL mode when the current view is a netlist view, the *tessent_design_gate_ports* attribute must be up to date. In most cases this will be true after

the `set_current_design` command is invoked. For sub-blocks it will only be true after `write_design` or `update_icl_attributes_from_design` is invoked. See “[Post-Synthesis Update](#)” in the *Tessent Shell User’s Manual* for further information.

- `-direction input | output`

An optional switch and literal pair that specifies to filter results based on the value of the `direction` attribute on the port object. When omitted, ports with any direction are considered.

- `-function function`

An optional switch and literal pair that specifies to filter results based on the value of the `function` attribute on the ICL port object. When omitted, ports with any function are considered. The value `function` is a Tcl list of function names derived from the ICL port function where multiple words are separated by underscores instead of using camel casing. For example, a port declared as a `ScanInPort` in ICL has function `scan_in` in the ICL data model.

- `-filter attribute_equation`

An optional switch and string that specifies to filter results based on the expression specified by the `attribute_equation` string. The attributes used within the equation must exist for the ICL port object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The `=~` and `!~` matching operators used simple wildcard matching versus Posix extended regular expression based on the presence of the `-regexp` option or not.

- `-regexp`

An optional switch that directs the tool to interpret the value of the `name_patterns` argument and the arguments of the `=~` and `!~` `-filter` expressions as regular expressions instead of as simple wildcard patterns. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.

- `-nocase`

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for ports matching the `name_patterns`.

- `-silent`

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the `name_patterns` disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options` [-change_no_result_warnings_to_errors](#) switch description for detailed usage.

Examples

Example 1

This example looks for ICL ports on the current design whose name match I* or O*.

```
get_icl_ports {I* O*}  
{I1 I2 I3 I4 I5 I6 I7 I8 O1 O2 O3}
```

Example 2

This example looks for scalar ports having one or two characters on module ModA.

```
get_icl_ports {[:alnum:]}{1,2} -regex -of_module ModA  
{ab a b}
```

Related Topics

[get_common_parent_instance](#)

[read_icl](#)

get_icl_scan_interface_chain_list

Context: all contexts

Mode: all modes

Returns the names of the explicitly defined scan chains for the specified client scan interface in an existing ICL top module, or the names of the explicitly defined scan chains for the specified client scan interface that are created in the new ICL top module during ICL extraction.

Usage

```
get_icl_scan_interface_chain_list -name name [-as_set]
```

Description

Returns the names of the explicitly defined scan chains for the specified client scan interface in an existing ICL top module, or the names of the explicitly defined scan chains for the specified client scan interface that are created in the new ICL top module during ICL extraction.

You must set the current design with `set_current_design` before using the `get_icl_scan_interface_chain_list` command.

Arguments

- **-name** *name*
A required switch and value pair that specifies the name of a scan interface, or a collection that contains exactly one element of type either “icl_scan_interface” or “icl_scan_interface_of_module” that specifies the scan interface, for which the list of explicitly defined scan chains is returned.
- **-as_set**
An optional switch that instructs the tool to return the specifications done by means of the `add_icl_scan_interfaces` command, even if there is already an ICL module for the current design.

Return Values

If the ICL top module exists and the `-as_set` switch has been omitted, this command returns the names of the explicitly defined scan chains for the specified ScanInterface.

If the ICL top module does not exist or the `-as_set` switch has been used, the command returns the names of the new scan chains for the ScanInterface specified with the `-chains` argument of the `add_icl_scan_interfaces` command, which are created during ICL extraction.

get_icl_scan_interface_list

Context: all contexts

Mode: all modes

Returns the names of the scan interfaces in an existing ICL top module, if the ICL top module exists.

Usage

```
get_icl_scan_interface_list [ -control_of object_spec | -as_set ]
```

Description

Returns the names of the scan interfaces in an existing ICL top module, if the ICL top module exists. If the ICL top module does not exist, it returns the names of the scan interfaces that are created in the new ICL top module by ICL extraction after the `add_icl_scan_interfaces` command has been used to specify the scan interfaces.

You must set the current design with `set_current_design` before using the `get_icl_scan_interface_list` command.

Arguments

- `-control_of object_spec`
An optional string that specifies an `object_spec` with at most one element, which is either an object of type `icl_scan_interface` or an object of type `icl_scan_register`.
The `-control_of` option cannot be used in the ICL extraction flow when there is no top level ICL.
- `-as_set`
An optional switch that instructs the tool to return the specifications done by means of the `add_icl_scan_interfaces` command, even if there is already an ICL module for the current design.

Return Values

When this command is used without the `-control_of` option, then if the ICL top module exists and the `-as_set` switch has been omitted, the command returns the `ScanInterface` names in the ICL top module. If the module does not have an explicit `ScanInterface` definition in the ICL module, but only an implicitly defined anonymous scan interface, the command returns “unnamed”. If the ICL top module does not exist or the `-as_set` switch has been used, the command returns the new `ScanInterface` names specified with the `add_icl_scan_interfaces` command, which are created during ICL extraction.

When the `-control_of` option is specified, the command returns a list of names (not a collection) of top level client scan interfaces, through which the given scan interface / the given scan register can be accessed.

Examples

The following example returns the ScanInterface names PG1 and PG2 in the ICL module pass1:

```
Module pass1 {  
    ScanInPort sin1;  
    ScanInPort sin2;  
    ScanOutPort sout;  
    ShiftEnPort sen;  
    CaptureEnPort cen;  
    SelectPort select1;  
    SelectPort select2;  
    UpdateEnPort uen;  
    ScanInterface PG1 {  
        Port sin1; Port sout; Port sen; Port cen; Port select1; Port uen;  
    }  
    ScanInterface PG2 {  
        Port sin2; Port sout; Port sen; Port cen; Port select2; Port uen;  
    }  
}
```

```
set_current_design pass1  
get_icl_scan_interface_list  
PG1 PG2
```

Related Topics

[add_icl_scan_interfaces](#)

[delete_icl_scan_interfaces](#)

[set_icl_scan_interface_ports](#)

get_icl_scan_interface_port_list

Context: all contexts

Mode: all modes

Returns the names of the ports for the specified scan interface in an existing ICL top module, or the names of the ports for the specified scan interface that are created in the new ICL top module during ICL extraction.

Usage

```
get_icl_scan_interface_port_list -name name [-chain chain_name] [-as_set]
```

Description

Returns the names of the ports for the specified scan interface in an existing ICL top module, or the names of the ports for the specified scan interface that are created in the new ICL top module during ICL extraction.

You must set the current design with `set_current_design` before using the `get_icl_scan_interface_port_list` command.

Arguments

- **-name** *name*

A required switch and value pair that specifies the name of a scan interface, or a collection that contains exactly one element of type either “icl_scan_interface” or “icl_scan_interface_of_module” that specifies the scan interface, for which the list of ports is returned. If the module does not have an explicit ScanInterface definition in the ICL module, but only an implicitly defined anonymous scan interface, then use the string “unnamed” for the scan interface name to get the ports of the anonymous scan interface.

- **-chain** *chain_name*

An optional switch and value pair that specifies the name of the scan chain for which the list of ports is returned. This switch is necessary for a scan interface that contains multiple scan chains that were specified in the `-chains` argument of the “`add_icl_scan_interfaces`” command.

- **-as_set**

An optional switch that instructs the tool to return the specifications done by means of the `set_icl_scan_interface_ports` command, even if there is already an ICL module for the current design.

Return Values

If the ICL top module exists and the `-as_set` switch has been omitted, this command returns the names of the ports for the specified ScanInterface.

If the ICL top module does not exist or the `-as_set` switch has been used, the command returns the names of the new ports for the ScanInterface specified with the `set_icl_scan_interface_ports` command, which are created during ICL extraction.

If a scan interface has multiple scan chains, calling the “`get_icl_scan_interface_port_list`” command without the `-chain` switch returns all ports apart from those of type `scan_in` or `scan_out`. When specifying the name of the scan chain with the `-chain` switch, only the ports of type `scan_in` and `scan_out` of the corresponding chain are returned.

Examples

Example 1

This example returns the list of ports for the ScanInterface named `default` in the ICL module `pass1`:

```
Module pass1{
  ScanInPort sin;
  ScanOutPort sout;
  SelectPort select;
  CaptureEnPort cen;
  ShiftEnPort shiftEn;
  UpdateEnPort updateEn;
  ScanInterface default {
    Port sin; Port sout; Port select; Port cen; Port shiftEn; Port
updateEn; DefaultLoadValue 3'b0;
  }
}
```

set_current_design pass1

get_icl_scan_interface_port_list -name default

sin sout select cen shiftEn updateEn

Example 2

This example returns the list of ports for the anonymous scan interface in the ICL module `pass2`:

```
Module pass2{
  ScanInPort sin;
  ScanOutPort sout;
  SelectPort select;
  CaptureEnPort cen;
  ShiftEnPort shiftEn;
  UpdateEnPort UpdateEn;
}
```

set_current_design pass2

get_icl_scan_interface_port_list -name unnamed

sin sout select cen shiftEn updateEn

[set_icl_scan_interface_ports](#)

get_icl_scan_mux

Context: patterns -silicon_insight -ijtag

Mode: setup

Returns various information about the specified scan mux node.

Usage

```
get_icl_scan_mux mux_name {-selected_input | -number_of_inputs | -selector}
```

Description

Returns various information about the specified scan mux node.

Use this command when manually debugging IJTAG networks as described in “[Diagnosing and Debugging IJTAG Networks](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

Arguments

- *mux_name*
A required string that specifies the name of a scan mux.
- -selected_input
An optional switch that returns the programmed selected input index for the specified scan mux.
- -number_of_inputs
An optional switch that returns the number of input signals for the specified scan mux.
- -selector
An optional switch that returns the selected signal(s) for the specified scan mux.

Examples

```
get_icl_scan_mux tap_I1.DRMux -selected_input
```

```
1
```

```
get_icl_scan_mux block3_I1.M1 -number_of_inputs
```

```
4
```

```
get_icl_scan_mux tap_I1.DRMux -selector
```

```
tap_I1.IR[1] tap_I1.IR[0]
```

get_icl_scope

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Introspects the current ICL scope.

Usage

```
get_icl_scope [-iCall | -iPrefix]
```

Description

When run without an option, this command returns the instance name prefix that is appended to the beginning of any ICL object names used in the [iCall](#), [iWrite](#), and [iRead](#) commands. When run with the `-iCall` option, this command ignores the current iPrefix specification and returns the ICL scope against which the current iProc is running. When run with the `-iPrefix` option, this command returns the current value specified for the iPrefix command.

For more information on the ICL scope, see the [iCall](#) command reference page.

Arguments

- `-iCall`
An optional literal that specifies to ignore the current iPrefix specification and return the ICL scope against which the current iProc is running. This path is useful to obtain the exact ICL instance the iProc was run against using the `iCall` command. You can use this value in an `iNote` as shown in the example below.
- `-iPrefix`
An optional literal that specifies to return the current value specified for the iPrefix command.

Return Values

An ICL instance path name.

Examples

In the following example, the iProc gets the ICL scope in which it was run against with the `iCall` command to echo into the retargeted pattern using an `iNote` command:

```
iProc myProc {} {  
    iNote "Running on Instance [get_icl_scope -iCall]"  
}
```

[iCall](#)

[iPrefix](#)

get_icl_ssn_datapath_list

Context: all contexts

Mode: all modes

Returns the SSN datapath specifications added with the `add_icl_ssn_datapaths`, or returns the list of SSN datapaths in the ICL module of the current design.

Usage

```
get_icl_ssn_datapath_list [-as_set]
```

Description

This command has different effects depending on the existence of an ICL module for the current design.

If there is no ICL for the current design, the command returns the specifications that have been added with the `add_icl_ssn_datapaths` command. This behavior can be enforced by using the `-as_set` switch even if there is ICL for the current design.

If there is ICL for the current design, the command returns the union of all elements in the `tessent_ssn_datapath_ids` attributes of the ICL ports of the ICL top module.

Arguments

- `-as_set`

A switch that instructs the tool to return the specifications that have been done by means of the `add_icl_ssn_datapaths` command even if there is ICL for the current design.

Examples

```
SETUP> add_icl_ssn_datapaths {A B C}  
SETUP> delete_icl_ssn_datapaths B  
SETUP> get_icl_ssn_datapath_list
```

```
A C
```

get_icl_ssn_datapath_ports

Context: all contexts

Mode: all modes

Returns the SSN datapath specifications specified with the `set_icl_ssn_datapath_ports` command, or returns the collection of the SSN datapaths ports of a particular type in the ICL module of the current design.

Usage

```
get_icl_ssn_datapath_ports -name datapath_id
    {-clock_inputs | -clock_outputs | -bus_data_inputs | -bus_data_outputs}
    [-as_set | -object_type {icl | design}]
```

Description

This command has different effects depending on the existence of an ICL module for the current design.

If there is no ICL for the current design, the command returns the specifications that have been done by means of `set_icl_ssn_datapath_ports`. This behavior can be enforced by using the `-as_set` switch even if there is ICL for the current design.

If there is ICL for the current design, the command returns the ports of the specified type that are associated with the specified SSN datapath. If the ICL ports have the `tessent_ssn_datapath_bus_index` attribute, the ports are returned in the correct order; the port with the highest bus index will be the first in the collection, the port with the smallest bus index will be the last in the collection. The `-object_type` switch allows you to specify the type of the elements in the result collection. Depending on the choice, the result will either be a collection of objects of type “`icl_port`” or a collection of objects of type “`port`”.

Arguments

- `-name datapath_id`
The name of the SSN datapath the tool returns.
- `-clock_inputs`
A switch that instructs the tool to return the collection of the clock input ports of the specified SSN datapath.
- `-clock_outputs`
A switch that instructs the tool to return the collection of the clock output ports of the specified SSN datapath.
- `-bus_data_inputs`
A switch that instructs the tool to return the collection of the bus data input ports of the specified SSN datapath.

- **-bus_data_outputs**
A switch that instructs the tool to return the collection of the bus data output ports of the specified SSN datapath.
- **-as_set**
A switch that instructs the tool to return the specifications that have been done by means of [set_icl_ssn_datapath_ports](#) even if there is ICL for the current design.
- **-object_type icl | design**
A switch and literal pair that specifies the object type for the elements in the result collection. If “icl” is used, the result will be a collection of objects of type “icl_port”. This is the default. If “design” is used, the result will be a collection of objects of type “port”.

Examples

```
SETUP> add_icl_ssn_datapaths {A B}
SETUP> set_icl_ssn_datapath_ports -name A -clock_inputs bus_clock \
    -bus_data_inputs bus_a_in[1:0] -bus_data_outputs bus_a_out[1:0]
SETUP> set_icl_ssn_datapath_ports -name B -clock_inputs bus_clock \
    -bus_data_inputs bus_b_in[3:0] -bus_data_outputs bus_b_out[3:0]
```

```
SETUP> get_icl_ssn_datapath_ports -name A -clock_inputs
```

```
bus_clock
```

```
SETUP> get_icl_ssn_datapath_ports -name A -clock_outputs
SETUP> get_icl_ssn_datapath_ports -name A -bus_data_inputs
```

```
{bus_a_in[1]} {bus_a_in[0]}
```

```
SETUP> get_icl_ssn_datapath_ports -name A -bus_data_outputs
```

```
{bus_a_out[1]} {bus_a_out[0]}
```

```
SETUP> get_icl_ssn_datapath_ports -name B -clock_inputs
```

```
bus_clock
```

```
SETUP> get_icl_ssn_datapath_ports -name B -clock_outputs
SETUP> get_icl_ssn_datapath_ports -name B -bus_data_inputs
```

```
{bus_b_in[3]} {bus_b_in[2]} {bus_b_in[1]} {bus_b_in[0]}
```

```
SETUP> get_icl_ssn_datapath_ports -name B -bus_data_outputs
```

```
{bus_b_out[3]} {bus_b_out[2]} {bus_b_out[1]} {bus_b_out[0]}
```

get_iclock_list

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Returns a list of ICL port and pin names on which you have issued an iClock command.

Usage

```
get_iclock_list [-overridden] [-within_current_pattern_set]
```

Description

Returns a list of ICL port and pin names on which you have issued an iClock command.

When you use the `-overridden` option, this command lists the ICL port and pin names on which you have issued an `iClockOverride` command on. You can use this list to introspect the effective source and the effective frequency multiplication and division values of the ICL pin or port using the `get_iclock_option [-overridden]` command.

Arguments

- `-overridden`
Specifies to return the ICL port and pin names on which an `iClockOverride` command was issued as opposed to the `iClock` command when the option is not specified.
- `-within_current_pattern_set`
Restricts the result of the command to the `iClock/iClockOverride` specifications that have been done within the currently opened pattern set.

Return Values

A Tcl list of ICL port and pin names.

Examples

In the following example, a Tcl list of ICL port and pin names are obtained using the `get_iclock_list` command. Their effective source and their effective frequency multiplication and division values are then echoed to the transcript

get_iclock_list

```
set iclock_list [get_iclock_list]
foreach iclock $iclock_list {
  puts "iClock pin or port: $iclock"
  puts " source = [get_iclock_option $iclock -source]"
  puts " freq_multiplier= [get_iclock_option $iclock -freq_multiplier]"
  puts " freq_divider = [get_iclock_option $iclock -freq_divider]"
}
```

get_iclock_option

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Returns the effective or specified source, source type, frequency multiplier, frequency divider, clock period and other information related to the iClock or iClockOverride commands for the specified icl_port or pin_name.

Usage

```
get_iclock_option icl_port_or_pin_name [-overridden]
    {-source | -source_type | -freq_multiplier | -freq_divider |
    -period [-in {as | fs | ps | ns | us | ms | s}] | -traversed_pins | -error_list }
```

Description

Returns the effective or specified source, source type, frequency multiplier, frequency divider, clock period and other information related to the iClock or iClockOverride commands for the specified icl_port or pin_name.

The specified icl_port_or_pin_name must have been the target of an iClock command when the -overridden option is not specified; it must have been the target of an iClockOverride command when the -overridden option is specified.

Arguments

- **icl_port_or_pin_name**
A required string that specifies the name of an ICL port or pin object on which an iClock or iClockOverride command has been issued.
- **-overridden**
An optional switch that specifies that icl_port or pin_name must be an icl_port or icl_pin object on which an iClockOverride command has been issued. If this switch is used, the return value of get_iclock_option is derived from the most recent matching iClockOverride command, instead of the most recent matching iClock command.
- **-source**
A required switch that specifies to return the effective source of an iClock ICL pin or port, or the specified source of an iClockOverride ICL pin or port.

- **-source_type**

A required switch that specifies to return the type of the effective source of an iClock ICL pin or port, or the specified source of an iClockOverride ICL pin or port. The result is one of the following: “primary”, “tck”, “internal” or “none”. The following table shows the meaning of the different source types:

Table 4-6. Source Types

type	without -override	with -override
primary	The effective source of the iClock pin or port is a ClockPort of the current design.	The specified source of the iClockOverride pin or port is a ClockPort of the current design.
tck	The effective source of the iClock pin or port is a TCKPort of the current design.	The specified source of the iClockOverride pin or port is a TCKPort of the current design.
internal	The effective source of the iClock pin or port is a ToClockPort with a “Period” property.	The iClockOverride command for the pin or port has a “-period” specification instead of a “-source” specification, or the “-source” specification refers to an internal ICL pin.
none	The specified ICL pin or port has not been subject to a successfully completed iClock command.	The specified ICL pin or port has not been subject to a successfully completed iClockOverride command.

The `-source_type` switch is special, in the sense that it can be used without error even if the specified ICL pin or port has not been subject to an iClock or iClockOverride command before. The return value “none” denotes this situation.

- **-freq_multiplier**

A required switch that specifies to return the effective frequency multiplier value of an iClock ICL pin or port, or the specified frequency multiplier value of an iClockOverride ICL pin or port.

- **-freq_divider**

A required switch that specifies to return the effective frequency divider value of an iClock ICL pin or port, or the specified frequency divider value of an iClockOverride ICL pin or port.

- **-period** [-in {as | fs | ps | ns | us | ms | s}]

A required switch that specifies to return the effective clock period of an iClock ICL pin or port, or the specified clock period of an iClockOverride ICL pin or port. You can optionally

use the `-in` switch and keyword to specify a particular time unit. For iClock specifications, the default time unit is derived from the time unit of the source clock. This is either the time unit used in the `-period` switch of the `add_clocks` command (in case of an asynchronous source clock) or the time unit of the `tester_period` (in case of a synchronous source clock). For iClockOverride specifications, the default time unit is derived from the unit that has been used during the processing of the `iClockOverride` command.

- **-traversed_pins**

A required switch that specifies to return a dictionary of pins that have been traversed during the processing of the `iClock` command. When you use the `-traversed_pins` switch, you cannot also use the `-overridden` switch. The structure of the result is a dictionary of dictionaries as follows:

```
{  <pin_name_1>  {  node_type      port | pin
                    inversion    0 | 1
                    freq_multiplier <int>
                    freq_divider   <int>
                }

    <pin_name_2>  {  node_type      port | pin
                    inversion    0 | 1
                    freq_multiplier <int>
                    freq_divider   <int>
                }

    ...

    <pin_name_n>  {  node_type      port | pin
                    inversion    0 | 1
                    freq_multiplier <int>
                    freq_divider   <int>
                }
}
```

The order of pins is from source to sink (iClock pin or port). Frequency multipliers, frequency dividers and inversions are accumulated appropriately.

- **-error_list**

A required switch that specifies to return a list of error messages associated with the iClock ICL pin or port. If the `-overridden` switch is used, the result is empty, because iClockOverride error messages are currently not collected.

Return Values

The value of the specified option for the specified `icl_port_or_pin_name`.

Examples

In the following example, a Tcl list of ICL port and pin names are obtained using the `get_iclock_list` command. Their effective source and their effective frequency multiplication and division values are then echoed to the transcript

get_iclock_option

```
set iclock_list [get_iclock_list]
foreach iclock $iclock_list {
  puts "iClock pin or port: $iclock"
  puts " source = [get_iclock_option $iclock -source]"
  puts " freq_multiplier= [get_iclock_option $iclock -freq_multiplier]"
  puts " freq_divider = [get_iclock_option $iclock -freq_divider]"
}
```

get_ijtag_instances

Context: dft, patterns

Mode: all modes

Returns a collection of instances for which there is a matched ICL module.

Usage

```
get_ijtag_instances [ijtag_instance_spec] [-below_instances instance_objects]  
    [-filter attribute_equation] [-map_to_icl_modules] [-silent]
```

Description

Returns a collection of instances for which there is a matched ICL module.

You can restrict the search to instances below a given collection of instances and filter the collection based on an arbitrary filtering equation involving other attributes registered against or inherited by the instance object type.

The `-silent` option suppresses the warning that is normally generated if no Ijtag instances are returned.

Arguments

- *ijtag_instance_spec*

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces (`{}`). If no *name_patterns* are specified, the tool searches all Ijtag instances.

If you specify the `-below_instances` options, the name patterns are hierarchical name patterns relative to the specified instance objects; otherwise the name patterns are relative to the current design.

- `-below_instances instance_objects`

An optional switch and value pair that constrains the command to search for instances below the specified *instance_objects*. The specified *name_patterns* are searched relative to each instance found in the *instance_objects* list.

If the specified *instance_spec* is an empty collection, all instances below the current design are considered. See the description of the `-below_instances` switch of the `get_instances` command description for the justification of this behavior.

- `-filter attribute_equation`

An optional switch and string that specify to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the instance object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering using the attribute equation format.

get_ijtag_instances

- `-map_to_icl_modules`

An optional switch that specifies to return only the collection of the ICL modules for the instances that are returned by the command when you do not specify this switch.

- `-silent`

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options -change_no_result_warnings_to_errors` switch description for detailed usage.

Examples

The following example uses the `get_ijtag_instances` command to get all instances of a module below a given instance for which there is a matched ICL file.

```
get_ijtag_instances -below_instance subblockA_i1
```

```
{subblockA_i1/tdr1 subblockA_i1/tdr2}
```

Related Topics

[get_ijtag_instance_option](#)

[report_ijtag_instances](#)

[set_ijtag_instance_options](#)

get_ijtag_instance_option

Context: dft, patterns

Mode: all modes

Returns the value of the selected option for the specified Ijtag instance.

Usage

```
get_ijtag_instance_option ijtag_instance_spec [-use_in_dft_specification]
[-connect_data_signals_already_connected_to_ports]
```

Description

Returns the value of the selected option for the specified Ijtag instance.

Arguments

- *ijtag_instance_spec*
A required literal that is the name of an ijtag instance or a collection containing one ijtag instance as reported by [get_instances](#) or [get_ijtag_instances](#).
The instance object must have an ICL module matched to it.
- -use_in_dft_specification
A Boolean option that specifies that the value of the -use_in_dft_specification option is required. This value is set using the [set_ijtag_instance_options](#) and is used by the [create_dft_specification](#) command.
- -connect_data_signals_already_connected_to_ports
A Boolean option that specifies that the value of the -connect_data_signals_already_connected_to_ports option is required. This value is set using the [set_ijtag_instance_options](#) and is used by the [create_dft_specification](#) command.

Examples

The following example returns the value of the use_in_dft_specification option of all Ijtag instances.

```
foreach_in_collection inst [get_ijtag_instances] {
  set opt [get_ijtag_instance_option $inst -use_in_dft_spec]
  puts "inst = [get_single_name $inst], use_in_dft_spec = $opt"
}

inst = u1/trd1, use_in_dft_spec = auto
inst = u1/trd2, use_in_dft_spec = auto
inst = u2/trd1, use_in_dft_spec = off
```

Related Topics

[get_ijtag_instances](#)

[report_ijtag_instances](#)

[set_ijtag_instance_options](#)

get_ijtag_retargeting_options

Context: all contexts

Mode: all modes

Returns the value of the specified option of the previous `set_ijtag_retargeting_options` command or its default value if the `set_ijtag_retargeting_options` command was not run.

Usage

`get_ijtag_retargeting_options` *getOption*

Description

Before using this command, you must load and elaborate the top-level ICL module. Otherwise, the tool prints an error message.

Arguments

- *getOption*

A required switch that can take one of the following values:

- test_setup_network_end_state — A switch that returns the value of the `-test_setup_network_end_state` option (keep or reset) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (reset) if the `set_ijtag_retargeting_options` command was not run.
- test_setup_ireset — A switch that returns the value of the `-test_setup_ireset` option (off, first_icall or when_icl_present) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (when_icl_present) if the `set_ijtag_retargeting_options` command was not run.
- iapply_target_annotations — A switch that returns the value of the `-iapply_target_annotations` option (off, dense, or full) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (dense) if the `set_ijtag_retargeting_options` command was not run.
- max_operations_per_iapply — A switch that returns the value of the `-max_operations_per_iapply` option specified by the previous `set_ijtag_retargeting_options` command or returns the default value (64) if the `set_ijtag_retargeting_options` command was not run.
- compare_constant_capture_values — A switch that returns the value of the `-compare_constant_capture_values` option (on or off) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (on) if the `set_ijtag_retargeting_options` command was not run.
- compare_constant_data_out_ports — A switch that returns the value of the `-compare_constant_data_out_ports` option for the primary DataOut ports (on or off) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (off) if the `set_ijtag_retargeting_options` command was not run.
- ignore_non_reset_end_state_implicit_compares — A switch that returns the value of the `-ignore_non_reset_end_state_implicit_compares` option (off, auto or on) specified

by the previous `set_ijtag_retargeting_options` command or returns the default value (auto) if the `set_ijtag_retargeting_options` command was not run.

- `constrain_update_en_only` — A switch that returns the value of the `-constrain_capture_en_only` option (auto or on) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (auto) if the `set_ijtag_retargeting_options` command was not run.
- `interface_type` — A switch that returns the value of the `-interface_type` option (auto, ijtag or tpsp) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (auto) if the `set_ijtag_retargeting_options` command was not run.
- `merge_irunloop_only` — A switch that returns the value of the `-merge_irunloop_only` option (on or off) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (off) if the `set_ijtag_retargeting_options` command was not run.
- `network_end_state_warnings` — A switch that returns the value of the `-network_end_state_warnings` option (on or off) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (off) if the `set_ijtag_retargeting_options` command was not run.
- `disable_pio_operations` — A switch that returns the value of the `-disable_pio_operations` option (on or off) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (off) if the `set_ijtag_retargeting_options` command was not run.
- `ignore_iwrite_when_value_already_present` — A switch that returns the value of the `-ignore_iwrite_when_value_already_present` option (on or off) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (off) if the `set_ijtag_retargeting_options` command was not run.
- `allow_skip_rti` — A switch that returns the value of the `-allow_skip_rti` option (on or off) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (on) if the `set_ijtag_retargeting_options` command was not run.
- `inject_cycles` — A switch that returns the value of the `-inject_cycles` option (Tcl list with an even number of arguments, each comprising a TAP state and the related number of injected cycles in alternating order) specified by the previous `set_ijtag_retargeting_options` command or returns the default value if the `set_ijtag_retargeting_options` command was not run.
- `tck_ratio` — A switch that returns the value of the `-tck_ratio` option (“auto” or a power of 2) specified by the previous `set_ijtag_retargeting_options` command or returns the default value (auto) if the `set_ijtag_retargeting_options` command was not run.

The value of `tck_ratio` might depend on the maximum tck clock frequency that can be applied to the circuit. See the “[IJTAG Network Performance Optimization](#)” section in the *Tessent IJTAG User’s Manual* showing how to maximize the frequency of the IJTAG network test clock.

- tck_period — A switch that returns the value of the -tck_period option specified by the previous set_ijtag_retargeting_options command or returns the default value (100ns) if the set_ijtag_retargeting_options command was not run.
- annotation_parameter_values — A switch that returns the value of the -annotation_parameter_values option (Tcl list with an even number of arguments, each comprising a key and a value in alternating order, describing the configuration of notes, comments and annotations in Tessent IJTAG) specified by the previous set_ijtag_retargeting_options command. If the set_ijtag_retargeting_options command was not run, then the tool returns the default value.

Examples

The following example loads the ICL, turns off the reset of the ICL network after the last test_setup PDL command and then displays the value of the selected option:

```
SETUP> set_context patterns -ijtag -no_rtl
SETUP> read_icl ../data/chip.icl
SETUP> set_current_design

// Note: Top design is 'chip'.

get_input_constraints

Context: dft, patterns

Mode: setup, analysis

Returns the present constraint status of primary input ports or pseudo ports.

Usage

```
get_input_constraints obj_spec { -equivalent_ports | -equivalent_inverted_ports |  
-constraint_value | -hold | -no_z | -slow_pad }
```

Description

The `get_input_constraints` command displays the constraint status of primary input pins to which you have applied constraints using the `add_input_constraints` command.

Arguments

- *obj_spec*
A required value that specifies a collection of ports and pseudo ports.
- `-equivalent_ports`
An optional switch that specifies to return the ports/pseudo ports that are defined as the non-inverted equivalent of the specified port/pseudo port. The *obj_spec* collection must contain exactly one port or pseudo port object.
- `-equivalent_inverted_ports`
An optional switch that specifies to return the ports/pseudo ports that are defined as the inverted equivalent of the specified port/pseudo port. The *obj_spec* collection must contain exactly one port or pseudo port object.
- `-constraint_value`
An optional switch that specifies to return the constraint values specified for the given ports/pseudo ports. The returned constraint values can be any of the following:
 - C0 — Constant 0
 - C1 — Constant 1
 - CX — Constant X (unknown)
 - CZ — Constant Z (high-impedance)
 - CR0 — Constant that returns to 0
 - CR1 — Constant that returns to 1
 - CT0 — Constant TIE0
 - CT1 — Constant TIE1
 - CTZ — Constant TIEZ

The values are returned as a Tcl list in the same order as the port and pseudo port objects specified with *obj_spec*. The returned Tcl list length equals the number of ports/pseudo ports specified with *obj_spec*. For the specified ports and pseudo ports that do not have a constraint defined, an empty Tcl list is returned.

- -hold

An optional switch that specifies to return a Tcl list of 0's and 1's depending on whether -hold was specified for the given port/pseudo ports. Default is 0. The values are returned as a Tcl list in the same order as the port and pseudo port objects specified with *obj_spec*. The returned Tcl list length equals the number of ports/pseudo ports specified with *obj_spec*. For the specified ports and pseudo ports that do not have a constraint defined, an empty Tcl list is returned.

- -no_z

An optional switch that specifies to return a Tcl list of 0's and 1's depending on whether -no_z was specified for the given port/pseudo ports. Default is 0. The values are returned as a Tcl list in the same order as the port and pseudo port objects specified with *obj_spec*. The returned Tcl list length equals the number of ports/pseudo ports specified with *obj_spec*. For the specified ports and pseudo ports that do not have a constraint defined, an empty Tcl list is returned.

- -slow_pad

An optional switch that specifies to return a Tcl list of 0's and 1's depending on whether -slow_pad was specified for the given port/pseudo ports. Default is 0. The values are returned as a Tcl list in the same order as the port and pseudo port objects specified with *obj_spec*. The returned Tcl list length equals the number of ports/pseudo ports specified with *obj_spec*. For the specified ports and pseudo ports that do not have a constraint defined, an empty Tcl list is returned.

Examples

Example 1

The following example adds constraints with the `add_input_constraints` command, then retrieves them with the `report_input_constraints` and `get_input_constraints` commands.

```
SETUP> add_input_constraints -equivalent A[2] B[1] B[0] -invert A[0] A[1]
```

```
SETUP> report_input_constraints
```

// Primary Input	Equivalent	C-Type	Hold	No-Z	Slow-Pad
// A[2]		NONE	No	Undetermined	No
//	~A[1]	NONE	No	Undetermined	No
//	~A[0]	NONE	No	Undetermined	No
//	B[0]	NONE	No	Undetermined	No
//	B[1]	NONE	No	Undetermined	No

```
SETUP> get_input_constraints A[0] -equivalent_ports
```

```
{A[1]}
```

```
SETUP> get_input_constraints A[1] -equivalent_ports
{A[0]}

SETUP> get_input_constraints A[2] -equivalent_ports
{B[0] B[1]}

SETUP> get_input_constraints A[0] -equivalent_inverted_ports
{A[2] B[0] B[1]}

SETUP> get_input_constraints A[2] -equivalent_inverted_ports
{A[0] A[1]}

SETUP> get_input_constraints A[2] -hold
0

SETUP> add_input_constraints A[4] -C1
SETUP> get_input_constraints A[12:0] -constraint_value
{} {} {} {} {} {} {} {} {} C1 {} {} {} {}

SETUP> get_input_constraints A[2] -no_z
0

SETUP> add_input_constraints A[2] -slow_pad
SETUP> get_input_constraints A[2] -slow_pad
1

SETUP> get_input_constraints {A[0] A[1] A[2]} -slow_pad
0 0 1

SETUP> add_input_constraints B[1] -CT1 -no_z
SETUP> get_input_constraints B[1] -constraint_value
CT1

SETUP> get_input_constraints B[1] -no_z
1
```

Example 2

The following examples check if a constraint is defined:

```
set conValue [get_input_constraints xyz/n_123 -constraint_value]
if { [length [index $conValue 0]] != 0 } {
  puts "Constraint is defined. "
} else {
  puts "Constraint not defined"
}
```

```
set ports [get_ports]
set constraints [get_input_constraints $ports -constraint_value]
for {set i 0} { $i < [llength $constraints] } { incr i } {
  if { [llength [index $constraints $i]] != 0 } {
    puts "Constraint is defined for port [get_name_list [index_collection $ports $i]]"
  } else {
    puts "Constraint not defined for port [get_name_list [index_collection $ports $i]]"
  }
}
```

get_insertion_option

Context: unspecified, all contexts

Mode: all modes

Returns the value of any insertion option that is specifiable with the `set_insertion_options` command.

Usage

```
get_insertion_option -auto_uniquify_edited_modules
| -edited_module_prefix
| -net_uniquification_suffix
| -module_uniquification_suffix
| -instance_uniquification_suffix
| -allow_assigns | -use_buffer_cell
| -inserted_object_comment_label
| -treat_common_ancestor_as_unique
| -preserve_paths_for_unrolled_v2001_loops
| -vhdl_port_pin_net_type
| -open_input_pins
| -remove_inactive_sections_in_unrolled_generate_loops
| -trace_across_module_boundaries_to_find_functional_drivers
| -undriven_created_input_message_severity
| -create_unique_net_names_in_module
| -gen_loop_net_size_threshold
| -edited_file_prefix
```

Description

Returns the value of any insertion option that is specifiable with the `set_insertion_options` command.

Only one option can be specified per `get_insertion_option` invocation. The return value is a string containing the current setting of the specified option. An error is generated if more than one option is specified, and the return value is null.

Arguments

- `-auto_uniquify_edited_modules`
A switch that returns the current setting of `-auto_uniquify_edited_modules` option of the `set_insertion_options` command.
- `-edited_module_prefix`
A switch that returns the current setting of the `-edited_module_prefix` option of the `set_insertion_options` command.

- **-net_uniquification_suffix**
A switch that returns the current setting of the `-net_uniquification_suffix` option of the [set_insertion_options](#) command.
- **-module_uniquification_suffix**
A switch that returns the current setting of the `-module_uniquification_suffix` option of the [set_insertion_options](#) command.
- **-instance_uniquification_suffix**
A switch that returns the current setting of the `-instance_uniquification_suffix` option of the [set_insertion_options](#) command.
- **-allow_assigns**
A switch that returns the current setting of the `-allow_assigns` option of the [set_insertion_options](#) command.
- **-use_buffer_cell**
A switch that returns the current setting of the `-use_buffer_cell` option of the [set_insertion_options](#) command.
- **-inserted_object_comment_label**
A switch that returns the current setting of the `-inserted_object_comment_label` option of the [set_insertion_options](#) command.
- **-treat_common_ancestor_as_unique**
A switch that returns the current setting of the `-treat_common_ancestor_as_unique` option of the [set_insertion_options](#) command.
- **-preserve_paths_for_unrolled_v2001_loops**
A switch that returns the current setting of the `-preserve_paths_for_unrolled_v2001_loops` option of the [set_insertion_options](#) command.
- **-vhdl_port_pin_net_type**
A switch that returns the current setting of the `-vhdl_port_pin_net_type` of the [set_insertion_options](#) command.
- **-open_input_pins**
A switch that returns the current setting of the `-open_input_pins` option of the [set_insertion_options](#) command.
- **-remove_inactive_sections_in_unrolled_generate_loops**
A switch that returns the current setting of the `-remove_inactive_sections_in_unrolled_generate_loops` option of the [set_insertion_options](#) command.

get_insertion_option

- `-trace_across_module_boundaries_to_find_functional_drivers`
A switch that returns the current setting of the `-trace_across_module_boundaries_to_find_functional_drivers` option of the [set_insertion_options](#) command.
- `-undriven_created_input_message_severity`
A switch that returns the current setting of the `-undriven_created_input_message_severity` option of the [set_insertion_options](#) command.
- `-create_unique_net_names_in_module`
A switch that returns the current setting of the `-create_unique_net_names_in_module` option of the [set_insertion_options](#) command.
- `-gen_loop_net_size_threshold`
A switch that returns the current setting of the `-gen_loop_net_size_threshold` option of the [set_insertion_options](#) command.
- `-edited_file_prefix`
A switch that returns the current setting of the `-edited_file_prefix` option of the [set_insertion_options](#) command.

Examples

The following example introspects the current setting of the `-edited_module_prefix` option of the [set_insertion_options](#) command.

```
get_insertion_option -edited_module_prefix
```

```
MyCore_
```

get_insert_test_logic_option

Context: dft -scan, dft -test_points

Mode: setup, analysis, insertion

Retrieves a prefix/infix value that is used when logic is created by the insert_test_logic command.

Usage

```
get_insert_test_logic_option [ -inserted_object_naming ] | [ -inserted_object_prefix ] |  
  [ -persistent_cell_prefix ] | [ -persistent_clock_cell_prefix ] |  
  [ -logic_type [ generic | clock_gater_fix | clock_control_fix | dedicated_input_wrapper |  
  dedicated_input_holding_wrapper | dedicated_output_wrapper | lockup | pipeline | ram_fix |  
  testpoint_control | testpoint_observation | tri_state_fix | x_bounding ] ] |  
  [ -reuse_modules_when_possible ] [ -generate_third_party_script ]
```

Description

The get_insert_test_logic_option command retrieves a prefix/infix value that is used when logic is created by the insert_test_logic command.

Arguments

- -inserted_object_naming
An optional switch that returns the default naming style of the instances and associated nets created during “insert_test_logic”.
- -inserted_object_prefix
An optional switch that returns the default prefix of HDL objects created during “insert_test_logic”.
- -persistent_cell_prefix
An optional switch that returns the default prefix of persistent cell instances created during “insert_test_logic”.
- -persistent_clock_cell_prefix
An optional switch that returns the default prefix of persistent clock cell instances created during “insert_test_logic”.
- -logic_type
An optional switch that returns the default infix of HDL objects created during “insert_test_logic” for a specified logic type. The possible logic types are as follows:
 - generic — Used for generic logic.
 - clock_gater_fix — Used for clock gater control logic.
 - clock_control_fix — Used for clock control logic.
 - dedicated_input_wrapper — Used for dedicated input wrapper logic.

dedicated_input_holding_wrapper — Used for dedicated input holding wrapper logic.

dedicated_output_wrapper — Used for dedicated output wrapper logic.

lockup — Used for lockup logic.

pipeline — Used for pipeline logic.

ram_fix — Used for ram control logic.

testpoint_control — Used for control testpoint logic.

testpoint_observation — Used for observation testpoint logic.

tri_state_fix — Used for tristate control logic.

x_bounding — Used for X-bounding logic

- -reuse_modules_when_possible

An optional switch that returns the default uniquification of new HDL modules for each instance created during “insert_test_logic”.

- -generate_third_party_script

An optional switch that returns the setting of third-party script generation specified with the set_insert_test_logic command.

Examples

The following example demonstrates the use of the get_insert_test_logic_option command.

```
SETUP> get_insert_test_logic_option -logic_type dedicated_input_wrapper
diw_

SETUP> set_insert_test_logic_options -logic_type dedicated_input_wrapper \
    -logic_infix inreg_
SETUP> get_insert_test_logic_option -logic_type dedicated_input_wrapper
inreg

SETUP> report_insert_test_logic_options
```

```

// 'insert_test_logic' Command Option           Current Value
// -----
// -inserted_object_naming                     standard
// -inserted_object_prefix                     ts_

get_instance_polygons

Context: patterns -scan_diagnosis

Mode: analysis

Returns Tcl list of the x, y coordinate location of the specified instance in the LDB.

Usage

```
get_instance_polygons instance_path [-ldb_units]
```

Description

This command returns the x and y coordinate location corresponding to a specified instance path in the LDB. The tool returns chip-level coordinates.

By default, the command returns coordinates expressed in microns units. You can override the default by specifying the -ldb_units switch.

Arguments

- `instance_path`
Required string that specifies the path to a polygon instance within the LDB.
- `-ldb_units`
An optional switch that returns the x, y coordinates in LDB units rather than the default micron units.

Related Topics

[get_xy_instance](#)

[report_instance_polygons](#)

[report_xy_instance](#)

get_instances

Context: all contexts

Mode: all modes

Returns a collection of all instances instantiated relative to the current design that match the specified *name_patterns* list, subject to filtering imposed by the specified options.

Usage

```
get_instances [name_patterns]  
  [-of_modules module_objects]  
  [-parent_of_instances instance_objects]  
  | -below_instances instance_objects  
  | -of_pins pin_objects  
  | -of_nets net_objects  
  | -of_gate_pins gate_pin_objects  
  | -of_icl_instances icl_instance_objects ]  
  [-of_type types]  
  [-hierarchical]  
  [-match_rtl_reg | -use_path_matching_options]  
  [-filter attribute_equation]  
  [-regexp]  
  [-nocase]  
  [-silent]
```

Description

Returns a collection of all instances instantiated relative to the current design that match the specified *name_patterns* list, subject to filtering imposed by the specified options.

When the *name_patterns* list is omitted, all instances are returned subject to filtering imposed by the specified options.

By default, the tool reports an error if the `get_instances` command returns no result unless you have set the `-silent` switch.

You can change no result Tcl errors to warnings by issuing the following command:

```
set_tcl_shell_options -change_no_result_warnings_to_errors off
```

Note

 This approach introduces a risk if your scripts cannot deal with empty collections correctly. As this may result in incorrect/unintended behavior, it is not recommended.

Arguments

- *name_patterns*

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces ({}). If no *name_patterns* are specified, the tool searches all instances.

After quick synthesis, you can specify the exact RTL paths here, and the tool finds the equivalent instance objects. This enables you to load a DftSpecification with RTL instance paths if the current views are quick synthesized.

If you specify one of the optional switches (-parent_of_instances, -of_pins, -of_nets, -of_gate_pins or -hierarchical), the name patterns are matched against the *leaf_name* attribute value of the instances in which case no hierarchy separators are permitted in the pattern list.

If you specify the -below_instances option, the name patterns are hierarchical name patterns relative to the specified instance objects otherwise the name patterns are relative to the current design.

- -of_modules *module_objects*

An optional switch and value pair that constrains the command to return only instances of modules specified by *module_objects*. The *module_objects* is a single module name, a Tcl list of module names, or a collection of module objects as returned by the [get_modules](#) command.

- -parent_of_instances *instance_objects*

An optional switch and value pair that constrains the command to return a collection of instance objects that are the parent instances of the specified *instance_objects*. The returned collection is filtered to only return a given parent instance once. When this option is specified, the optional *name_patterns* option is a string that is matched against the leaf instance name of every parent instance of the collection. An error is generated if the specified *name_patterns* contain more than one level of hierarchy when the -parent_of_instances option is used.

- -below_instances *instance_objects*

An optional switch and value pair that constrains the command to search for instances below the specified *instance_objects*. The tool searches the specified *name_patterns* relative to each instance found in the *instance_objects* list. If the *instance_objects* is a null collection or a null string, the switch is ignored and instances are searched relative to the current design.

An exception is made for this switch to treat an empty collection as meaning the current design such that it could accept the return value of “get_instances -parent_of_instance XXX” even if XXX is directly instantiated into the current design. Very often, you want to create an instance or find objects in the same parent instance of another instance. If the -below_instances switch did not accept a null collection as meaning the current design, you could not use this simple form:

```
get_instances -below_instance [get_instances -parent_of_instance XXX]
```

You would always have to make an exception for instances found directly below the current design as follows:

```
set parent_instance [get_instances -parent_of_instance XXX]
if {[sizeof_collection $parent_instance] > 0} {
  get_instances
} else {
  get_instances -below_instances $parent_instance
}
```

Because an empty collection is interpreted as meaning the current design when passed to the `-below_instances` switch, you do not need the above exception code handling to handle instances directly instantiated in the current design differently from those instantiated at least two levels below the current design.

- `-of_pins pin_objects`

An optional switch and value pair that constrains the command to return the instance on which the pins belong to. The returned collection is filtered to only return a given instance once even if it belongs to many pins in the *pin_objects* list. When this option is specified, the optional *name_patterns* is a string that is matched against the leaf instance name of the instances. An error is generated if the specified *name_patterns* contain more than one level of hierarchy when the `-of_pins` option is used.

- `-of_nets net_objects`

An optional switch and value pair that constrains the command to return the instance in which the net objects are located. The returned collection is filtered to only return a given instance once even if it is the parent instance of many nets in the *net_objects* list. When this option is specified, the optional *name_patterns* is a string that is matched against the leaf instance name of the instances. An error is generated if the specified *name_patterns* contain more than one level of hierarchy when the `-of_nets` option is used.

- `-of_gate_pins gate_pin_objects`

An optional switch and value pair that constrains the command to return the collection of instances to which the gates associated with the gate pins belong. The returned collection is filtered to only return a given instance once even if it belongs to many gate pins in the *gate_pin_objects* list. When this option is specified, the optional *name_patterns* is a string that is matched against the leaf instance name of the instances. An error is generated if the specified *name_patterns* contain more than one level of hierarchy when the `-of_gate_pins` option is used.

If the specified *gate_pin* exists under one or many levels of ``celldefine` module instances, the highest-level ``celldefine` module instance is returned. In addition, *gate_pins* directly under the root module return an empty ("") string as the instance.

- `-of_icl_instances icl_instance_objects`

An optional switch and value pair that constrains the command to return the instances corresponding to the specified *icl_instance_objects*. The *icl_instances_objects* can be retrieved using the [get_icl_instances](#) command. If the tool is successful, it returns a collection of these instances. If not, it reports an error unless the `-silent` switch is specified.

- **-of_type *types***

An optional switch and value pair that constrains the tool to return only instances whose type attribute is one of the following: design, cell, or primitive. The types value is either a single type string or a Tcl list of type strings such as {design cell}.
- **-hierarchical**

An optional string that specifies to perform pattern matching relative to all instances found below the current design or below the specified *instance_objects* when the **-below_of_instances** option is specified. When this option is specified, the *name_patterns* argument cannot include slashes, which are hierarchy separator symbols.
- **-match_rtl_reg**

An optional switch that performs register name-mapping using the rules you specified for RTL to post-synthesis/post-layout name mapping. Using this option enables you to find the register with the register mapping rules. See [add_rtl_to_gates_mapping](#) for complete information.
- **-use_path_matching_options**

An optional switch that performs instance name-mapping using rules you specified for RTL to post-synthesis/post-layout name mapping. Using this option enables you to find an instance using the instance mapping rules. See [add_rtl_to_gates_mapping](#) for complete information.
- **-filter *attribute_equation***

An optional switch and string that specify to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the instance object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format.
- **-regexp**

An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a real regular expression instead of as a simple wildcard pattern. You must properly escape the bracket “[]” symbols so that they are interpreted as part of the regular expression and not interpreted by the Tcl shell. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.
- **-nocase**

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for instances matching the *name_patterns*.
- **-silent**

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This **-silent** option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options` [-change_no_result_warnings_to_errors](#) switch description for detailed usage.

Examples

Example 1

The following example returns a collection of all instances of cell types that start with ABC found anywhere below the current design.

```
get_instances ABC* -hierarchical -of_type cell  
{u2/ABCD u1/u5/ABCDEF}
```

Example 2

The following example starts with the collection of all instances and filters it based on an `attribute_equation` of user-defined attributes.

```
get_instances -filter {myType1 || myType2 == "ABC"}  
{u2 u1/u5}
```

Example 3

The following example starts with the collection of all instances and filters it based on the expression specified by the `attribute_equation` string.

```
get_instances -filter {name=~"u4*/u1*"}  
{u4/u1 u4/u5/u1}
```

Example 4

In the following example, the collection of all instances matching a list of hierarchical name patterns are additionally filtered to only return instances of type `design`. The names `u1/*` and `u*/u*` are searched relative to the current design.

```
get_instances {u1/* u*/u*} -of_type design  
{u4/u5}
```

Example 5

In the following example, the collection of all instances matching a leaf name pattern is returned. The leaf instance name `u3*` searches for all instances found below the current design.

```
get_instances u3* -hierarchical  
{u3 u4/u3 u4/u5/u3 u5/u3}
```

Example 6

In the following example, the collection of all instances matching a leaf name pattern is returned. The leaf instance name `u3*` is matched against instances found below instance `u4`.

```
get_instances u3* -hierarchical -below_instances u4
```

```
{u4/u3 u4/u5/u3}
```

Example 7

In the following example, the `-parent_of_instances` option is used to find the parent instance of each instance on which a collection of pins exist. Only the parent instances whose leaf instance names match `ABC*` are returned. As described in the description of the `-parent_of_instances` switch, the optional `name_pattern` argument, in this case `ABC*`, is a string that is matched against the leaf instance name of every parent instance of the collection when the `-parent_of_instances` option is used.

```
set pin [get_pins]
```

```
get_instances ABC* -parent_of_instances [get_instances -of_pins $pin]
```

```
{u4/ABC1 u4/u5/ABC2}
```

Alternatively, you could use the `base_name` attribute of the pin objects and the `parent_instance` attribute of the instances to achieve the same result. However, the method used in this example is much more efficient because it deals with objects instead of strings containing object names. This method also avoids issues with string concatenation in the presence of escaped identifiers.

Example 8

This example returns all design instances that correspond to all ICL instances. It uses the [get_icl_instances](#) command to retrieve the ICL instances.

```
get_instances -of_icl_instances [get_icl_instances]
```

```
// { block1_I1/raw1_I1 block1_I1/raw1_I2 block1_I1/sib1_I1 block1_I1/sib1_I2 ...}
```

Example 9

This example returns the equivalent instance object for the given RTL name. Generate blocks (generate for/if/case) are flattened after quick synthesis (the generate blocks are removed and the hierarchical names are added to the instance base names). For example, `"B1[1].B2.u1"` becomes `"\B1[1].B2.u1"`, and `"\B1[1].B2.u1"` also becomes `"\B1[1].B2.u1"`.

```
get_instances B1[1].B2.u1
```

```
{\B1[1].B2.u1 }
```

```
get_instances {{B1[1].B2.u1}}
```

```
{\B1[1].B2.u1 }
```

```
get_instances {{B1[1].B2.u1}}
```

```
{\B1[1].B2.u1 }
```

```
get_instances {{B1[1].B2.u1 }}  
{\B1 [1] .B2 .u1 }
```

get_instrument_dictionary

Context: all contexts including the unspecified one

Mode: all modes

Returns the Tcl dictionary created by the instrument processed by `process_dft_specification` or `process_patterns_specification`.

Usage

```
get_instrument_dictionary [dictionary_name [{key_name}...]] [-list] [-silent | -exists]
```

Description

Returns the content of a Tcl dictionary entry or the list of available dictionaries.

Use the `-list` option to see the currently available dictionary. At startup, the only dictionary available is `tshell_global`. Once you have run the `process_dft_specification` command, other dictionaries become available based on the instrument types that were processed.

The content of the dictionary is useful when you are writing customization scripts as described in the “[process_dft_specification.post_insertion Procedure](#)” on page 1353. For example, to know the extension of the RTL files that were created and stored in the `instruments` directory, use:

```
get_instrument_dictionary DftSpecification rtl_extension
```

For Tessent MissionMode in-system test, this command returns a dictionary named “`mentor::in_system_test::PatternsSpecification`” when you run the `process_patterns_specification` command to generate in-system test patterns. You can use the dictionary to help you program the CPU as described in “[Guidelines for Programming the CPU for In-System Test](#)” in the *Tessent MissionMode User’s Manual*.

See the “[Instrument Dictionary](#)” section for the description of the dictionary created by the boundary scan instrument.

Arguments

- *dictionary_name* [{*key_name*}...]
An optional dictionary name followed by any number of keys from that dictionary. If no keys are specified, then the entire dictionary is returned.
- **-list**
An optional Boolean switch that request the command to return the list of available instrument dictionaries. At startup, the only dictionary available is `tshell_global`. Once you have run the `process_dft_specification` command, other dictionaries become available based on the instrument types that were processed.

- **-silent**

An optional Boolean switch that suppresses the error that is normally produced when a dictionary or key is requested and the dictionary or key does not exist. With this switch, no errors is generated and the command returns a null value.

- **-exists**

An optional Boolean switch that request the command to return 1 if the specified dictionary and key combination exist and returns 0 otherwise.

Examples

Example 1

Suppose you want to know the extension of the interface module created in the [dft_inserted_designs](#) directory when the current design is a Verilog module read in with format sv2005. You can query the dictionary using this command:

```
get_instrument_dictionary tshell_global Format2ExtensionMapping verilog sv2005
```

The command returns “sv05” and the interface module has the extension sv05_interface. To see the entire mapping list, use the following command:

```
format_dictionary [get_instrument_dictionary tshell_global Format2ExtensionMapping]
```

which returns the complete sub-dictionary.

The following example uses the -list switch to see the available dictionaries. It then shows how to display the entire “tshell_global” dictionary and its format using the [format_dictionary](#) command. The example then returns the value of the “Format2ExtensionMapping verilog 1995” key. The effect of the -silent and -exists switches are them shown.

```
get_instrument_dictionary -list
```

```
tshell_global
```

```
format_dictionary [get_instrument_dictionary tshell_global]
```

```

v95

get_instrument_dictionary tshell_global junk

```
// Error: The specified dictionary 'tshell_global' does not contain the  
// requested key 'junk'.
```

```
get_instrument_dictionary tshell_global junk -silent
```

```
get_instrument_dictionary tshell_global junk -exists
```

```
0
```

Example 2

This example shows how to use the command to introspect the dictionary created by the [process_dft_specification](#) command based on the wrapper types that were processed. The dictionary `mentor::ijtag::DftSpecification` describes several aspects of the IJTAG network that the tool just processed. You can use the dictionary to retrieve the precise instance for the created nodes so that you can do custom editing within the [process_dft_specification.post_insertion](#) callback procedure.

get_instrument_dictionary -list

get_instrument_parent_icl_module_list

Context: dft and patterns

Mode: analysis, insertion, and setup

Returns the parent or grandparent module names for ICL instance module names that match the specified *instrument_module_name*.

Usage

get_instrument_parent_icl_module_list *instrument_module_name*

Description

Returns the parent or grandparent module names for ICL instance module names that match the specified *instrument_module_name*. This command is useful to find all the actual ICL module names when it has been uniquified.

The tool returns the grandparent module name only when the `icl_module` attribute `tessent_instrument_subtype` of the ICL instances is `shared_bus_assembly`.

```
foreach module_name [get_instrument_parent_icl_module_list <instrument_controller_name> {  
  iProcsForModule $module_name  
  iProc ...  
}]
```

The tool automatically inserts the command in the generated PDL files of the instrument.

Arguments

- *instrument_module_name*

A required string that specifies the module name to use in the module name matching.

get_iproc_argument_default

Context: all contexts

Mode: all modes

Returns the default value for the specified `arg_name` of the specified `proc_name` attached to the ICL module specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Usage

```
get_iproc_argument_default proc_name arg_name [-exists] [-of_module module_name]  
[-silent]
```

Description

Returns the default value for the specified `arg_name` of the specified `proc_name` attached to the ICL module specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

This command returns a null string when the specified argument has no default value. If you specify the `-exists` option, this command returns true if the specified argument has a default value and returns false when it does not.

Arguments

- ***proc_name***
A required string that specifies the name of the iProc.
- ***arg_name***
A required string that specifies the name of the argument.
- **-exists**
An optional switch that changes the returned value of the command. When present, the command returns true when the specified argument has a default value and returns false when it does not. When not specified, the command returns the default value when it exists; otherwise it returns null.
- **-of_module *module_name***
An optional switch and value pair that constrains the command to return only the default value for the specified `arg_name` of the specified `proc_name` attached to the module specified by `module_name`.
- **-silent**
An optional switch that specifies to suppress error messages if the specified `proc_name`, `arg_name` or `module_name` do not exist.

Return Values

If the `-exist` option is specified, this command returns true if the specified argument has a default value and returns false when it does not. If the `-exist` option is not specified, the command returns the default value when it exists; otherwise it returns null.

Examples

The following example lists each argument attached to the P1 iProc on module mychip and lists its default value, if one exists; otherwise it reports the argument does not have a default value.

```
foreach arg [get_iPROC_argument_list P1 -of_module mychip] {
  if {[get_iPROC_argument_default P1 $arg -exist]} {
    puts "Argument $arg has no default value"
  } else {
    set def [get_iPROC_argument_default P1 $arg]
    puts "Argument $arg has default value of $def"
  }
}
```

get_iproc_argument_list

Context: all contexts

Mode: all modes

Returns the list of argument names for the specified iProc attached to the ICL module that was specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Usage

```
get_iproc_argument_list iproc_name [-of_module module_name] [-silent]
```

Description

Returns the list of argument names for the specified iProc attached to the ICL module that was specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Arguments

- ***iproc_name***
A required string that specifies the name of the iProc for which the arguments are returned.
- `-of_module module_name`
An optional switch and value pair that constrains the command to return only instances of iProcs attached to the module specified by `module_name`.
- `-silent`
An optional switch that specifies to suppress error messages if the specified iProc or module do not exist.

Return Values

A Tcl list that contains the argument names of the specified iProc.

Examples

The following example assigns the arguments attached to the `chiptest` iProc on module `mychip` to the variable `chiptest_args`:

```
set chiptest_args [get_iproc_argument_list chiptest -of_module mychip]
```

Related Topics

get_iproc_body

Context: all contexts

Mode: all modes

Returns the body for the specified iProc attached to the ICL module that was specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Usage

```
get_iproc_body iprocs_name [-of_module module_name] [-silent]
```

Description

Returns the body for the specified iProc attached to the ICL module that was specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Arguments

- *iprocs_name*
A required string that specifies the name of the iProc.
- `-of_module module_name`
An optional switch and value pair that constrains the command to return only the body of iProcs attached to the module specified by `module_name`.
- `-silent`
An optional switch that specifies to suppress error messages if the specified iProc or module do not exist.

Return Values

None

Examples

The following example returns the body of the `chiptest` iProc attached to module `mychip`:

```
get_iproc_body chiptest -of_module mychip
```

Mode: all modes

Returns a Tcl list of iProcs attached to the ICL module specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Usage

```
get_iproc_list [-of_module module_name] [-silent]
```

Description

Returns a Tcl list of iProcs attached to the ICL module specified by the last `iProcsForModule` command, or to the ICL module specified by `module_name`.

Arguments

- `-of_module module_name`
An optional switch and value pair that constrains the command to return only instances of iProcs attached to the module specified by `module_name`.
- `-silent`
An optional switch that specifies to suppress error messages if the specified module does not exist.

Return Values

A Tcl list of the iProc names, which are registered against the ICL module specified by the last `iProcsForModule` command or the ICL module specified by `module_name`.

Examples

The following example assigns the list of iProcs attached to the mychip ICL module to the variable `myprocs`:

```
set myprocs [get_iproc_list -of_module mychip]
puts $myprocs
```

get_layout_core_instance

Context: patterns -scan_diagnosis

Mode: setup, analysis

Returns the current layout core instance that was set with the set_layout_core_instance command.

Usage

get_layout_core_instance

Description

Returns the current layout core instance that was set with the set_layout_core_instance command.

Arguments

None

Related Topics

[report_scan_polygons](#)

[set_layout_core_instance](#)

get_license_queue_timeout

Context: all contexts

Mode: all modes

Returns the value specified by the previous `set_license_queue_timeout` command.

Usage

```
get_license_queue_timeout
```

Description

Returns the value specified by the previous `set_license_queue_timeout` command. The command returns the default value of “unlimited” if you have not issued the `set_license_queue_timeout` command in the current tool session.

Arguments

None

Examples

The following example sets the license queue timeout value to 3 minutes, then displays the timeout value that was set:

```
SETUP> set_license_queue_timeout 3
SETUP> get_license_queue_timeout

3
```

Related Topics

[set_license_queue_timeout](#)

get_load_unload_timing_option

Context: all contexts

Mode: all modes

Returns the value for load/unload timing options set with the `set_load_unload_timing_options` command for an `icl_module`, a module, the `current_design`, or the current physical block.

Usage

```
get_load_unload_timing_option
  [-icl_module icl_module_name
   | -module module_name
   | -current_design
   | -current_physical_block]
  [-usage {ssn}]
  {-shift_clock_period [-time_unit {s | ms | us | ns | ps | fs | as_is}]
   | -ssn_bus_clock_period [-time_unit {s | ms | us | ns | ps | fs | as_is}]
   | -scan_en_setup_extra_cycles
   | -scan_en_hold_extra_cycles
   | -edt_update_setup_extra_cycles
   | -edt_update_hold_extra_cycles}
```

Description

Returns the value for load/unload timing options set with the `set_load_unload_timing_options` command for an `icl_module`, a module, the `current_design`, or the current physical block.

If you specified a module with the `set_current_physical_block` command and the load/unload options for the module, the tool returns those values. If you did not specify a module, the tool traverses the design hierarchy until it finds a parent that was specified as a physical block. Otherwise, the tool uses the module inherited from the current design, and returns the default values if no options were set.

If the module has multiple instantiations and all its instances inherit from the same parent, then the tool returns the values of that parent. If the instances of module inherit from different parents (see [Figure 4-6](#)), then the tool issues the following error:

```
// Error: The specified Module 'foo' was not set as a physical block by
// 'set_current_physical_block' command. It has multiple instances that
// do not belong to the same physical block.
```

For example, [Figure 4-6](#) shows that module A was never specified as a physical block, and module B was specified as physical block. Because module A has two instances, one of them inherits from block B and the other inherits from current design TOP. This scenario will result in an error.

Figure 4-6. Design Inheritance and Module Matching

Arguments

- `-icl_module icl_module_name`
 A switch and string pair that specifies the name of a valid ICL module from which to return the load/unload timing option.
- `-module module_name`
 A switch and string pair that specifies the name of a module from which to return the load/unload timing option.
- `-current_design`
 A switch that returns the load/unload timing option for the current design.
- `-current_physical_block`
 A switch that returns the load/unload timing option for the current physical block.
- `-usage {ssn}`
 An switch and literal pair that returns the SSN usage for the literal you specify.
- `-shift_clock_period [-time_unit {s | ms | us | ns | ps | fs | as_is}]`
 A switch, and optional switch and literal pair that returns the value as defined by the “[set_load_unload_timing_options -shift_clock_period](#)” command.
 The `-time_unit` switch-value pair is an optional Boolean option that can be used when the command is returning a Value time property value; it is ignored otherwise. When specified or defaulted to `as_is`, the time value is returned unmodified with the unit string specified if it existed in the value of the configuration element. When specified to a value other than `as_is`, the time value is converted into a real number formatted to the specified units. The unit string is also dropped. The default is nanoseconds (ns).
- `-ssn_bus_clock_period [-time_unit {s | ms | us | ns | ps | fs | as_is}]`
 A switch, and optional switch and literal that returns the value as defined by the “[set_load_unload_timing_options -ssn_bus_clock_period](#)” command.

The `-time_unit` switch-value pair is an optional Boolean option that can be used when the command is returning a Value time property value; it is ignored otherwise. When specified or defaulted to `as_is`, the time value is returned unmodified with the unit string specified if it existed in the value of the configuration element. When specified to a value other than `as_is`, the time value is converted into a real number formatted to the specified units. The unit string is also dropped.

- `-scan_en_setup_extra_cycles`

A switch that returns the value as defined by the “[set_load_unload_timing_options -scan_en_setup_extra_cycles](#)” command.

- `-scan_en_hold_extra_cycles`

A switch that returns the value as defined by the “[set_load_unload_timing_options -scan_en_hold_extra_cycles](#)” command.

- `-edt_update_setup_extra_cycles`

A switch that returns the value as defined by the “[set_load_unload_timing_options -edt_update_setup_extra_cycles](#)” command.

- `-edt_update_hold_extra_cycles`

A switch that returns the value as defined by the “[set_load_unload_timing_options -edt_update_hold_extra_cycles](#)” command.

Examples

The following example returns the shift clock period of the `current_design`.

```
get_load_unload_timing_option -current_design -shift_clock_period
```

get_loadboard_loopback_option

Context: patterns -ijtag, -scan, -scan_diagnosis, -scan_retargeting

Modes: Setup, analysis

Prerequisites: Design must be elaborated prior to using this command.

Returns the settings of options specified with the `add_loadboard_loopback` pairs command.

Usage

```
get_loadboard_loopback_option {-inputs | -outputs | -ac_delay_to_z}
```

Description

The `get_loadboard_loopback_option` returns the setting of a single option specified with the [add_loadboard_loopback_pairs](#) command

Arguments

- `-inputs`
An optional switch that returns a collection of all input ports that are part of a loopback.
- `-outputs`
An optional switch that returns a collection of all output ports that are part of a loopback.
- `-ac_delay_to_z`
An optional switch that returns the `ac_delay`.

Examples

This example shows how you use this command to get each option set in the `add_loadboard_loopback_pair`:

```
add_loadboard_loopback_pairs -inputs {din[4] ue} -outputs {dout[5] dout[0]} \  
-ac_delay_to_z 10ns
```

```
get_loadboard_loopback_option -inputs
```

```
{din[4] ue}
```

```
get_loadboard_loopback_option -outputs
```

```
{dout[5] dout[0]}
```

```
get_loadboard_loopback_option -ac_delay_to_z
```

```
10ns 10ns
```

get_logfile

Context: unspecified, all contexts

Mode: all modes

Returns the name of and pathway to the current log file.

Usage

get_logfile

Description

Returns the name of and pathway to the current logfile as set by the tool invocation's `-logfile` *logfile_name* switch and value, or the value you set using the [set_logfile_handling](#) command.

Arguments

None.

Related Topics

[set_logfile_handling](#)

get_logical_library_list

Context: all contexts

Mode: all modes

Prerequisites: You must be in the -rtl context.

Returns a Tcl list with all logical design library names defined with the `set_logical_design_libraries` command.

Usage

```
get_logical_library_list [-default_library]
```

Description

Returns a Tcl list with all logical design library names defined with the [set_logical_design_libraries](#) command.

This command and the concept of logical libraries is only available in the RTL mode.

This command is useful for writing scripts that operate on all libraries such as in Example3 of the [get_modules](#) command reference.

Arguments

- `-default_library`
An optional switch that specifies that the returned list only contains the default library.

Return Values

A Tcl list containing all logical design library names defined with the `set_logical_design_libraries` command.

Examples

In the following example, the Tcl variable `libs` is defined by the result returned by the `get_logical_library_list` command. You can then use a `foreach` command to iterate on the list elements.

```
set libs [get_logical_library_list]
```

Related Topics

[set_logical_design_libraries](#)

get_master_module_name

Context: all contexts

Mode: all modes

Returns a string with the master_name attribute value for a design or icl module.

Usage

```
get_master_module_name [obj_spec] [-icl]
```

Description

When `get_master_module_name` is invoked without any arguments, a string is returned containing the master_name attribute value of the current design module. If the design is not elaborated, an empty string is returned.

The *obj_spec* string needs to match exactly one design or icl_module, or a collection consisting of one design module or icl_module. Specifying a design module returns the master_name attribute value for that design module. When specifying an icl_module, the -icl switch is also used to return the master_name attribute value for that icl_module. When *obj_spec* is a collection containing one design module or icl_module, the -icl switch is ignored, and the master_name attribute value of the specified design module or icl_module is returned.

Invoking `get_master_module_name` with only the -icl switch returns a string that contains the master_name attribute value of the current icl top module, or an empty string if there is no icl elaboration.

Arguments

- *obj_spec*
An optional switch that specifies a single design or icl module, or a collection that contains one design module or icl module.
- -icl
An optional switch that specifies a string of the master_name attribute value for the specified icl module is returned. An empty string is returned if the design is not icl elaborated.

get_memory_instances

Context: dft

Mode: all modes

Prerequisite: The current design must be set with the `set_current_design` command.

Returns a collection of the instances for which there is a matched TCD Memory description.

Usage

```
get_memory_instances [name_patterns]  
    [-below_instances instance_objects]  
    [-filter attribute_equation] [-silent]  
    [-external_repair_ready]  
    [-repairable] [-non_repairable]  
    [-type memory_type]
```

Description

Returns a collection of instances for which there is a matched TCD Memory description. See “[Tessent Core Description](#)” on page 4471 for more information.

Memory instances within a lower level sub-block or physical block are excluded from the reporting. You can restrict the search to instances below a given collection of instances, and filter the collection based on an arbitrary filtering equation involving other attributes registered against or inherited by the instance object type.

If none of the options of this command is used, the command returns a collection that contains all of the memory instances in the design.

The `-silent` option suppresses the warning that is normally generated if no memory instances are returned.

Arguments

- *name_patterns*

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces `{}`. If no *name_patterns* are specified, the tool searches all memory instances.

If you specify the `-below_instances` option, the name patterns are hierarchical name patterns relative to the specified instance objects; otherwise, the name patterns are relative to the current design.

- `-below_instances` *instance_objects*

An optional switch and value pair that constrains the command to search for instances below the specified *instance_objects*. The specified *name_patterns* are searched relative to each instance found in the *instance_objects* list.

If the specified *instance_spec* is an empty collection, all instances below the current design are considered. See the description of the [-below_instances switch](#) of the [get_instances](#) command description for the justification of this behavior.

- *-filter attribute_equation*

An optional switch and string pair that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the instance object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering using the attribute equation format.

- *-silent*

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This *-silent* option has no effect on any other error reporting.

Note

 You can use the *-silent* switch to manage the case in which an empty collection is returned. Before using the *-silent* switch for this purpose, refer to the [set_tcl_shell_options -change_no_result_warnings_to_errors](#) switch description for detailed usage.

- *-external_repair_ready*

An optional switch that returns a collection of memory instances that are compatible for external repair. External repair is implemented with the [set_memory_instance_options -generate_external_repair_logic](#) command and option.

- *-repairable*

An optional switch that returns a collection of memory instances that contain spare elements within their memory TCD definitions. The collection does not contain memory instances that are within a [MemoryCluster](#).

- *-non_repairable*

An optional switch that returns a collection of memory instances the do not contain spare elements within their memory TCD definitions. The collection does not contain memory instances that are within a [MemoryCluster](#).

- *-type memory_type*

An optional switch and string pair that returns a collection of memory instances in which the specified *memory_type* matches the [MemoryType](#) property specified in the memory TCD (sram, rom, or dram), or cluster for memory instances that are within a [MemoryCluster](#).

Examples

The following example uses the `get_memory_instances` command to return all instances of a module below a given instance for which there is a TCD Memory description.

get_memory_instances -below_instance subblockA_i1

```
{subblockA_i1/mem1 subblockA_i1/mem2}
```

[set_memory_instance_options](#)

get_memory_instance_option

Context: all contexts

Mode: all modes

Prerequisite: The current design must be set with the `set_current_design` command.

Returns the value of an option on a specific memory instance, or returns the value of an option that applies to all memory instances.

Usage

```
get_memory_instance_option {memory_instance [-bist_data_in_pipelining |  
-physical_cluster_override | -power_domain_island | -test_clock_override |  
-use_in_memory_bist_dft_specification | -use_in_memory_bisr_dft_specification] |  
-generate_external_repair_logic |  
-repair_sharing | -partitioning_group} |  
-physical_cluster_size_ratio
```

Description

Returns the value of an option on a specific memory instance, or returns the value of an option that applies to all memory instances.

Arguments

- *memory_instance*
A required string that specifies the name of a memory instance or a collection containing a single memory instance. You can use the “[foreach_in_collection inst \[get_memory_instances\]](#)” command to iterate on all memory instances. You can use this option with any option other than `-physical_cluster_size_ratio`.
- `-bist_data_in_pipelining`
A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -bist_data_in_pipelining](#)” command on the specified `memory_instance`.
- `-physical_cluster_override`
A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -physical_cluster_override](#)” command on the specified `memory_instance`.
- `-power_domain_island`
A Boolean option that specifies to return the computed power domain island for the specified `memory_instance`. This property is only defined when a UPF or CPF file was initially read in using the [read_cpf](#) or [read_upf](#) commands and you are in the analysis system mode. Two memories share a common power domain island name when they have the same [power_domain_name](#) and the two instances are not logically separated by instances having a different `power_domain_name`. For example, memories in `u1` and memories in `u1/u2/u3`

sharing a common `power_domain_name` are in two power domain islands if `u1/u2` is associated with a different `power_domain_name`.

- `-test_clock_override`

A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -test_clock_override](#)” command on the specified `memory_instance`.

- `-use_in_memory_bist_dft_specification`

A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -use_in_memory_bist_dft_specification](#)” command on the specified `memory_instance`. In analysis system mode, the value `auto` is replaced by `on` or `off` depending on whether the memory instance is already connected to a memory BIST interface module.

- `-use_in_memory_bisr_dft_specification`

A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -use_in_memory_bisr_dft_specification](#)” on the specified `memory_instance`. In analysis system mode, the value `auto` is replaced by `on` or `off` depending on whether the memory instance is already connected to a memory BISR register module.

- `-generate_external_repair_logic`

A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -generate_external_repair_logic](#)” command on the specified `memory_instance`.

- `-repair_sharing`

A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -repair_sharing](#)” command on the specified `memory_instance`.

- `-partitioning_group`

A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -partitioning_group *group_label*](#)” command on the specified `memory_instance`.

- `-physical_cluster_size_ratio`

A Boolean option that specifies to return the value previously specified with the “[set_memory_instance_options -physical_cluster_size_ratio](#)” command. You cannot use this option together with the `memory_instance` option since it applies to all memory instances.

Examples

The following example performs a query using the `-use_in_memory_bist_dft_specification` option in both setup and analysis mode. Note how the value “`auto`” converts to “`on`” in the

analysis mode. This means the memory instance is not already connected to a memory BIST interface module.

```
SETUP> get_memory_instance_option -use_in_memory_bist_dft_specification
```

```
auto
```

```
SETUP> check_design_rules
```

```
...
```

```
ANALYSIS> get_memory_instance_option -use_in_memory_bist_dft_spec
```

```
on
```

[set_memory_instance_options](#)

get_module_matching_options

Context: all contexts

Mode: all modes

Returns the settings specified with the `set_module_matching_options` and the “`set_insertion_options -edited_module_prefix`” commands for module matching.

Usage

Usage 1

```
get_module_matching_options {-prefix_pattern_list | -suffix_pattern_list}
    [-regex | -nocase]
```

Usage 2

```
get_module_matching_options -format format_type
    -excluded_modules_from_module_matching
```

Usage 3

```
get_module_matching_options -module_name_map_list
```

Description

Returns the settings for module matching as specified by [set_module_matching_options](#) commands and the “`set_insertion_options -edited_module_prefix`” commands.

Depending on the arguments you specify, the tool returns the following:

- A list of prefixes.
- A list of suffixes.
- A list of 1s and 0s identifying if the corresponding element of the prefix or suffix pattern list is a regexp or a glob expression.
- A list of 1s and 0s identifying if the corresponding element of the prefix or suffix pattern list is to be matched irrespective of case or not.
- A collection of excluded modules that are not considered during module matching for the defined format specified with the “`set_module_matching_options -format`” command.

Arguments

- `-prefix_pattern_list`
A switch that instructs the tool to return the list of prefixes as defined by [set_module_matching_options](#) command. This includes module prefixes you assign with the “`set_insertion_options -edited_module_prefix`” command and switch.

- **-suffix_pattern_list**

A switch that instructs the tool to return a list of suffixes as defined by [set_module_matching_options](#) command.
- **-regex**

An optional switch to the `prefix_pattern_list` or the `suffix_pattern_list` switch that instructs the tool to return a list of 1s and 0s identifying if the corresponding element of the prefix or suffix pattern list is to be matched irrespective of case or not.
- **-nocase**

An optional switch to the `prefix_pattern_list` or the `suffix_pattern_list` switch that instructs the tool to return the set 'no case sensitive' values as 1 (on) or 0 (off) in the same sequence of the prefixes or suffixes as a list.
- **-format *format_type***

A switch and literal pair that instructs the tool to return a collection of modules to be ignored during module matching for the format type you specified with the “[set_module_matching_options](#) -format ... -excluded_modules_from_module_matching” command. The `-format` switch is *mandatory* when you specify the `-excluded_modules_from_module_matching` switch.

format_type must be one of the following:

 - icl
 - tcd_bscan
 - tcd_scan
 - tcd_fusebox
 - tcd_memory
 - tcd_memory_cluster
- **-excluded_modules_from_module_matching**

A switch used in conjunction with the `-format` switch that instructs the tool to return a collection of modules to be ignored during module matching with the format type you specified with the “[set_module_matching_options](#) -format ... -excluded_modules_from_module_matching” command. The `-format` switch is *mandatory* when you specify the `-excluded_modules_from_module_matching` switch.

If nothing was previously set for the specified format, an empty collection is returned.
- **-module_name_map_list**

A switch that instructs the tool to return a list of patterns as defined by the “[set_module_matching_options](#) -module_name_map_list *list_forming_mapping_pairs*” command.

Examples

The following demonstrates various uses of the `get_module_matching_options` command:

```

set_module_matching_options -prefix_pattern_list "none_" -suffix_pattern_list ""

set_module_matching_options -prefix_pattern_list "www" -regexp -append

set_module_matching_options -prefix_pattern_list "pre" -append

set_module_matching_options -prefix_pattern_list "pre_" -append

set_module_matching_options -prefix_pattern_list "pre" -append

set_insertion_options -edited_module_prefix "pre"report_module_matching_options

// Option                               Value
// -----
// case insensitivity override off
//
// affix type  regexp  pattern  by insertion*
// -----
// prefix      no      "none_"  no
// prefix      yes     "www"    no
// prefix      no      "pre"    no
// prefix      no      "pre_"   yes
// suffix      no      ""        no
// by insertion*: Additional prefix for ICL format defined by command
// 'set_insertion_options -edited_module_prefix'

[set_module_matching_options](#)

get_module_parameter_list

Context: all contexts

Mode: all modes

Returns the list of parameters in a module.

Usage

get_module_parameter_list *module_object* [-overridden]

Description

Returns the list of parameters in a module.

There are restrictions you need to consider when you use this command on a module without a definition

- Only parameters that are specified on instantiation can be determined.
- The returned list of parameters is the same whether or not you use the `-overridden` switch.
- When parameters are not specified by name, but by order, the tool generates a name. The generated name is a sequential integer, starting at zero, indicating the position of the parameter on the instantiation.

This command is only available in `-rtl` mode (`set_context dft -rtl`). For more information, see the [set_context](#) command.

Arguments

- *module_object*
A required string that specifies the parameterized module objects whose parameters are to be returned.
- `-overridden`
An optional switch that specifies to only list those parameters whose default values are overridden during an instantiation.

Return Values

List of parameters.

Examples

Example 1

In the following example, the [get_module_parameter_list](#) is used to obtain the list of parameters overridden in the specific instantiation.

```
set inst u1/myinst_i1
set params [get_module_parameter_list [get_modules -of_instances $inst] -overridden]
```

Example 2

This example shows the names generated by the tool when parameters are not specified by name but by order.

```
set mods [get_module -of_instance [get_instances]]
foreach_in_collection mod $mods {
  puts "--- Module [get_single_name $mod] ---"
  foreach param [get_module_parameter_list $mod] {
    puts "parameter $param = [get_module_parameter_value $param -of_module $mod]"
  }
}

--- Module DW01_add@PV1 ---
parameter 0 = 8
--- Module DW01_add@PV2 ---
parameter 0 = 16
--- Module def_named@PV1 ---
parameter d_size = 3
parameter q_size = 4
--- Module def_ordered@PV1 ---
parameter d_size = 2
parameter q_size = 5
--- Module nodef_named@PV1 ---
parameter d_size = 3
parameter q_size = 4
--- Module nodef_ordered@PV1 ---
parameter 0 = 2
parameter 1 = 5
```

get_module_parameter_value

Context: all contexts

Mode: all modes

Returns the value of the parameter on the specified module object.

Usage

`get_module_parameter_value parameter_name [-of_module module_object]`

Description

Returns the value of the parameter on the specified module object.

This command is only available in -rtl mode (`set_context dft -rtl`). For more information, see the [set_context](#) command.

Arguments

- *parameter_name*
A required string that specifies the name of the parameter whose value is to be returned.
- `-of_module module_object`
An optional switch and string pair that specifies the design module whose parameter value is to be returned. When omitted, the parameters of the current design are introspected.

Return Values

The value of the requested design module parameter.

Examples

In the following example, the values of all overridden parameters are echoed in the transcript.

```
set inst [get_instance u1/myinst_i1]
set mod [get_modules -of_instances $inst]
set params [get_module_parameter_list $mod -overridden]
foreach param $params {
    puts "parameter $param = [get_module_parameter_value $param \
        -of_mod $mod]"
}
```

get_modules

Context: all contexts

Mode: all modes

Returns a collection of all modules that match the specified *name_patterns* list.

Usage

```
get_modules [name_patterns] [-use_module_matching_options]
  [-in_library library] [-vhdl_architecture architecture]
  [returnModules]
  [-of_type type]
  [-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Description

Returns a collection of all modules that match the specified *name_patterns* list.

By default, this command returns all modules below the current design, and all modules present in memory, for example those modules you have read into the tool but are not yet instantiated. You can use the `-of_instances` and `-below_instances` arguments to constrain the search. If no modules exist in memory, the command returns an empty collection.

You can have any number of wildcards or regular expressions in the name patterns.

In the `rtl` context, you may have more than one logical library. Because VHDL is also supported in the `rtl` context, you may also have multiple architectures. You define the list of available logical libraries using the [set_logical_design_libraries](#) command.

In the `no_rtl` context, only one library exists and is it named “work”.

The tool searches for the objects specified by the *name_patterns* argument in all libraries unless the `-in_library` option is specified. All other commands that have an option that refers to module names only search the default library. For example, you use the following command to create an instance of module M1 from library L1:

```
create_instance instance_name -of_module [get_module M1 -in_library L1]
```

In another example, an instance of module M1 from the default library is created because only the `get_modules` command knows how to look into other libraries.

```
create_instance instance_name -of_module M1
```

Arguments

- *name_patterns*

An optional string or Tcl list of strings that specifies one or more patterns to be used to match the returned list of modules against. If no *name_patterns* are specified, the tool searches all modules.

- `-use_module_matching_options`

An optional switch that instructs the command to return a collection of all the modules that can be found by combining the suffix and the prefix specifications from the [set_module_matching_options](#) command with the given *name_patterns*. This option is useful when you are looking for modules by names that were potentially uniquified during synthesis. When you use this switch, the *name_patterns* list is mandatory and cannot include wildcards. The `-regexp` and `-nocase` switches are ignored. The module name matching for parameterized modules is based on the module base names, such that the returned collection includes the base module as well as all its parameterized views.

Note

The settings and the functionality of the module matching process are used to retrieve the results, but previous module matching results are not taken into account.

- `-in_library library`

An optional switch and value pair that specifies to restrict the search to a specified library. The library value must be a single string corresponding to one of the logical library names defined with the [set_logical_design_libraries](#) command. When the `-in_library` option is not specified, all libraries are searched. This option is only permitted in the rtl context.

Using `-in_library XXX` is equivalent to using `-filter "library_name == XXX"`.

- `-vhdl_architecture architecture`

An optional switch and value pair that specifies to restrict the search to a specific VHDL architecture name. This option is only useful when searching VHDL modules. When this option is not specified, one module per available architecture is returned. This option is only permitted in the rtl context.

Using `-vhdl_architecture XXX` is equivalent to using `-filter "vhdl_architecture == XXX"`.

- `returnModules`

An optional switch that can take one of the following values:

`-of_instances instance_objects` — An optional switch and value pair that constrains the command to return only modules of the specified *instance_objects*. You could use the `module_name` attribute of the instance objects to perform a similar filtering but this method is more direct and efficient and automatically deals with libraries and architectures.

`[-below_instances instance_objects] [-uniquified]` — An optional switch and value pair that constrains the command to return only modules corresponding to instances found below the specified *instance_objects*. If the specified *instance_spec* is an empty collection, all instances below the current design are considered. See the description of the [-below_instances switch](#) of the [get_instances](#) command description for the justification of this behavior.

`-uniquified` — An optional switch to return a collection of modules that were uniquified since entering insertion mode.

Note

 You can use the `-uniquified` switch with or without the `-below_instances` switch.

`-of_ports port_objects` — An optional switch and value pair that constrains the command to return only modules of the specified *port_objects*. You could perform a similar filtering operation using the `module_name` attribute of the port objects but using this switch is more direct and efficient and automatically deals with libraries and architectures.

Note

 This switch cannot be used with the `-of_instances` or `-below_instances` switch.

`-of_icl_modules icl_module_objects` — An optional switch and value pair that constrains the command to return the modules corresponding to the specified *icl_module_objects*. The *icl_module_objects* can be retrieved using the [get_icl_modules](#) command. If the tool is successful, it returns a collection of these modules. If not, it reports an error unless the `-silent` switch is specified.

`-parameterized_views_of_modules module_objects` — An optional switch and value pair that constrains the command to return a collection of modules corresponding to all the parameterized views of the module objects specified. The *module_objects* can be specified as a Tcl list of module names or a collection of modules. Whether *module_objects* contains a parameterized view or the master copy of the module, this switch instructs the command to find all parameterized views and return them. Using this switch is equivalent to using the `master_name` attribute of a module and requesting all modules having the same `master_name` value. Using this switch, however, is more efficient, and it also handles logical libraries. Use this switch to determine whether a module is uniquely instantiated or not and to find out if a module has multiple parameterized views.

`-original_module_of module` — An optional switch and value pair that returns the original module from which the module was copied. A module is copied from another module either by unification or with the [copy_module](#) command. The *module* parameter can be the name of a single module or a collection of one module. The module may be a parameterized view of the copied module. The tool returns the master copy of the original module. If the specified *module* is not a copied module, the tool reports an error unless the `-silent` switch is used in which case an empty collection is returned.

- `-of_type type`

An optional switch and value pair that constrains the command to return only modules of the specified types. The *type* is a Tcl list of one or more strings matching one of the following values: `design` or `cell`.

- `-filter attribute_equation`

An optional switch and string pair that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the module object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The `=~` and `!~` matching operator use

simple wildcard matching versus Posix extended regular expression based on the presence of the `-regexp` option.

- `-regexp`

An optional switch that directs the tool to interpret the value of the `name_patterns` argument as a real regular expression instead of as a simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.

- `-nocase`

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for modules matching the `name_patterns`.

- `-silent`

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the `name_patterns` disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options -change_no_result_warnings_to_errors` switch description for detailed usage.

Examples

Example 1

The following example looks for modules whose name matches `a*` or `b*`.

```
get_modules {a* b*}  
{ab abc b bcd}
```

Example 2

The following example looks for modules having one or two characters.

```
get_modules {[:alnum:]{1,2}} -regexp  
{ab b}
```

Example 3

The following example gets the module object associated to an instance.

```
get_modules -of_instances u3/u5  
{myModule}
```

Example 4

The following example looks for modules in all libraries and displays their names and language value in a tabular format.

```

set format_string " "
append format_string "module_name = %-10s "
append format_string "language = %-10s "

set libs [get_logical_library_list]foreach lib $libs {
  puts "Modules in library $lib are:"
  set mods [get_modules -in_library $lib]
  foreach_in_collection mod $mods {
    puts [format $format_string \
      [get_att_val $mod -name name]\
      [get_att_val $mod -name language]]
  }
}

Modules in library lib1 are:
  module_name = dut           language = verilog
Modules in library lib2 are:
  module_name = dut           language = verilog
Modules in library work are:
  module_name = top           language = verilog

```

Example 5

This example shows how to report the names of the parameterized views for a module.

```

puts "[get_name_list [get_modules -parameterized_views_of_modules ff]]"

ff ff@PV1 ff@PV2

```

Example 6

The `-use_module_matching_options` switch is used to look for modules based upon the prefix and suffix values defined by the `set_module_matching_options` command.

```

//Setting the prefix and suffix module matching option

set_module_matching_options -prefix_pattern_list {a*}\ -suffix_pattern_list {_1 _2}

// Getting the modules

puts [join [get_name_list [get_modules {mymodule}\ -use_module_matching_options]] "\n"]

//The returned modules are:

a_mymodule
a_mymodule_1
a_mymodule_2
ab_mymodule
ab_mymodule_1
ab_mymodule_2
mymodule
mymodule_1
mymodule_2

```

Example 7

In this example, the `-use_module_matching_options` switch is used to look for parametrized modules based upon the suffix values defined here by the related defaults for the module matching process.

```
// Getting the current active suffixes for the module matching process  
get_module_matching_options -suffix_pattern_list  
  
{ [_] + [0-9] + }  
  
// Getting the modules  
get_modules SYNC_1RW_GENERIC -use_module_matching_options  
  
{ SYNC_1RW_GENERIC_1 SYNC_1RW_GENERIC_1@PV1 SYNC_1RW_GENERIC_1@PV2 }
```

Example 8

This example gets a collection of all `read_cell_library` models that contain a `_ram`, `_rom`, or `_cram` primitive at any level within that cell's hierarchy.

```
get_modules -of_type cell -filter has_ram_or_rom_primitives
```

[create_module](#)

get_multiprocessing_option

Context: unspecified, dft -edt, patterns -scan

Mode: setup, analysis, insertion

Returns the value of a single specified variable previously set with the `set_multiprocessing_options` command.

Usage

```
get_multiprocessing_option {-generic_delete | -generic_scheduler  
| -license_timeout  
| -lsf_heuristics | -lsf_learning | -lsf_options | -multithreading  
| -processors_per_grid_request | -remote_shell | -result_time_limit  
| -scheduler_timeout | -sge_options}
```

Description

Returns the value of a single specified variable previously set with the [set_multiprocessing_options](#) command.

The `get_multiprocessing_option` command returns the value of a single multiprocessing variable that affects the behavior of the tool's built-in multiprocessing manager. These are values that you can set with the [set_multiprocessing_options](#) command. To display the values of multiprocessing variables in a human-readable format, use the [report_multiprocessing_options](#) command.

For more information about setting up for multiprocessing, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User's Manual* and “[The Tessent Tcl Interface](#)” in the *Tessent Shell User's Manual*.

Arguments

The arguments for the `get_multiprocessing_option` command are identical to those of the [set_multiprocessing_options](#) command, described on [page 2587](#). For more information about the purpose of each switch, refer to the list of arguments there.

Examples

The following example sets and then returns the value of the `remote_shell` variable:

```
set_multiprocessing_options -remote_shell rsh  
puts [get_multiprocessing_option -remote_shell]  
  
rsh
```

get_name_list

Context: unspecified, all contexts

Mode: all modes

Returns the names of the specified objects, or the names of the name list with simplified escaped identifiers, if possible.

Usage

```
get_name_list {object_spec | -from_object_names name_list [-language {verilog | vhdl}]}  
    [-remove_escaping] [-silent]
```

Description

This command returns a list with the value of the name attribute for the objects specified by *object_spec* or the names of the *name_list* with simplified escape identifiers, if possible.

Using this command is equivalent to running the following command:

```
get_attribute_value_list object_spec -name name
```

Using this command with the “**-from_object_names** *name_list*” option verifies the existence of the names in the design and removes simple escaped identifiers if they are not reserved words in the design language. You can use this to identify name strings with reserved design language words.

The **-language** argument defines which design language escaping should be removed while processing the **-from_object_names** name list.

The **-remove_escaping** argument removes the backslash (“\”) and the trailing spaces in an escaped identifier. Many legacy commands such as **add_clocks** require the instance name to have the escape character stripped from its name. The argument also removes the escaping on reserved design language words. However, these legacy commands accept collections as inputs in cases where the name format is not important. See the Examples section in this topic for an illustration of this behavior.

If *object_spec* or *name_list* entries are not valid, an error message displays unless the **-silent** switch is specified.

Arguments

- *object_spec*

A required string that specifies a Tcl list of one or more object names, or a collection of one or more objects.

- **-from_object_names *name_list*** [-language {*verilog* | *vhdl*}]

A required switch and string or Tcl list of object name strings pair, with an optional switch and literal pair. Simple escaping in parts of the names is removed from the defined language type if they are not language-specific reserved words.

-language {*verilog* | *vhdl*}

An optional switch and literal pair that specifies which language (Verilog or VHDL) should be considered during the removal of simple escaping. The default is Verilog when this option is not specified.

- **-remove_escaping**

An optional switch that specifies to strip out the \ and the trailing spaces in escaped identifiers. This option is useful to interact with legacy commands and the collection is not directly passed as input to them. See Example 2 for an illustration of this usage.

- **-silent**

An optional switch that specifies to suppress error messages if an object in *object_spec* does not exist.

Examples

Example 1

The following example retrieves the names for a collection of pins.

```
get_name_list [get_pins u1/i*]  
{u1/i1 u1/i2 u1/i3}
```

Example 2

The following example illustrates the use of the **-remove_escaping** option. In this example, you can see how legacy commands natively support collections as input arguments but do not support names with escaped identifiers.

Note the use of the double set of braces when specifying a name pattern containing escape identifiers to **get_pins**. These braces are needed to prevent the Tcl shell from interpreting the backslash character (“\”) as its own escape sequence. You could also escape the backslash using `{\xyz_i# /a}` but using two sets of braces is easier when the pattern includes many slashes. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a complete description of pattern syntax and suggestions to use when the pattern is targeted for names containing escape characters.

```
get_pins xyz*/*  
{{\xyz_i# /a} {\xyz_i# /b} {\xyz_i# /c_in} {\xyz_i# /s} {\xyz_i# /c_out}}
```

```
add_clocks [get_pins xyz*/*]
```

get_name_list

```
// Warning: Primary input '\xyz_i# /b_pport' is added at pin
'\xyz_i# /b'
// Warning: Primary input '\xyz_i# /c_in_pport' is added at pin
'\xyz_i# /c_in'
// Warning: Primary input '\xyz_i# /s_pport' is added at pin
'\xyz_i# /s'
// Warning: Primary input '\xyz_i# /c_out_pport' is added at pin
'\xyz_i# /c_out'
```

add_clocks {xyz_i# /a}

```
// Error: '
    yz_i# is not a primary input.
```

set names [get_name_list [get_pins xyz*/*] -remove_escaping]

```
{xyz_i#/a} {xyz_i#/b} {xyz_i#/c_in} {xyz_i#/s} {xyz_i#/c_out}
```

add_clocks \$names**Example 3**

The following example retrieves the names from a Tcl list of names of instances and instance pins with the `-from_object_names` option.

```
puts "from_object_names [get_name_list -from_object_names {{deep_input1/input /output
.le} {deep_input1/input} {d/a /b /c .le}}]"
from_object_names {deep_input1/input /output .e} {deep_input1/input} d/a/b/c.e
```

Due to name escaping, the names are defined in braces for the same reason as described in Example 2. Hierarchy separators are retained, so the “.” is not changed to “/”. The “input” and “output” name parts are Verilog keywords, so the escaping is not removed at those name sections. The last name does not contain keywords, so the escaping is removed.

Example 4

The following example retrieves the names from a Tcl list of names of instances and instance pins with the `-from_object_names` option.

```
puts "from_object_names [get_name_list -from_object_names {{deep_input1/input /output
.le} {deep_input1/input} {d/a /b /c .le}} -remove_escaping]"
from_object_names deep_input1/input/output .e deep_input1/input d/a/b/c.e
```

Due to name escaping, the names are defined in braces for the same reason as described in Example 2. Hierarchy separators are retained, so the “.” is not exchanged to “/”. The “input” and “output” name parts are Verilog keywords but also removed due to the `-remove_escaping` switch. The last name does not contain keywords, so the escaping is removed.

get_nets

Context: all contexts

Mode: all modes

Returns a collection of all hierarchical nets instantiated relative to the current design that match the specified `name_patterns` list, subject to filtering imposed by the specified options.

Usage

```
get_nets [name_patterns] [-below_instances instance_objects]  
      [-of_pins pin_objects | -of_ports port_objects | -of_gate_pins gate_pin_objects  
      |-of_pseudo_ports pseudo_port_objects] [-bundle]  
      [-hierarchical] [-filter attribute_equation] [-regexp] [-nocase] [-silent]
```

Description

Returns a collection of all hierarchical nets instantiated relative to the current design that match the specified `name_patterns` list, subject to filtering imposed by the specified options.

When the `name_patterns` list is omitted, all nets are returned subject to filtering imposed by the specified options.

Arguments

- `name_patterns`

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of nets. The string is a Tcl list of patterns separated by spaces and enclosed in braces `{ }`. If no `name_patterns` are specified, the tool searches all nets. The following limitations apply:

- You can use wildcards in `name_patterns`, but you cannot use a wildcard as part of the left or right index of a range. For example: `[* : <right_index>]` is not supported.
- A range (a dimension of the form `[<left_index> : <right_index>]`) can only be used in the last dimension of the last field of the `name_patterns`.

See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a complete description of the pattern syntax when the `-regexp` option is used and not used.

- `-below_instances instance_objects`

An optional switch and value pair that constrains the command to search for nets below the specified `instance_objects`. Specified `name_patterns` are searched relative to the specified `instance_objects` when this option is used.

If the specified `instance_spec` is an empty collection, all instances below the current design are considered. See the description of the `-below_instances switch` of the [get_instances](#) command description for the justification of this behavior.

- **-of_pins** *pin_objects*
An optional switch and value pair that constrains the command to return the net objects associated to the *pin_objects*. Those are the nets having the exact same name as the pins and residing inside the instances on which the pins are on. For pins of cells, the inside nets corresponding to the pins are not visible and thus not returned. You cannot use a *name_patterns* list when using this option. To get the net connected to pins from the outside, use `get_fanin` and `get_fanout -stop_on net`.
- **-of_ports** *port_objects*
An optional switch and value pair that constrains the command to return the net objects associated to the *port_objects*. Those are the nets having the exact same name as the ports and reside inside the current design. You cannot use a *name_patterns* list when using this option.
- **-of_gate_pins** *gate_pin_objects*
An optional switch and value pair that constrains the command to return the net objects associated to the *gate_pin_objects*. If a pin exists with the same name as the net, the net is returned using the command “`get_nets -of_pins`” and the “`get_nets -of_gate_pins`” command returns an empty collection. The command also returns an empty collection if the *gate_pin* is a port, in which case the command “`get_nets -of_ports`” returns the net you need. Refer to [Example 7](#) in the `get_pin` command section for an example usage.
- **-of_pseudo_ports** *pseudo_port_objects*
An optional switch and value pair that constrains the command to return the net objects associated to the *pseudo_port_objects*. If the pseudo port is defined on a pin, the pin is returned using the command `get_pins -of_pseudo_ports` while `get_nets -of_pseudo_ports` returns an empty collection. You can use this switch in combination with the `-silent` switch to determine if a pseudo_port was created on a net. Refer to [Example 6](#) in the `get_pin` command section for an example usage.
- **-bundle**
An optional switch that constrains the command to return net bundle objects. When specified, the tool traverses the bundle hierarchy of all root bundle objects declared in the selected view (current design or other views selected by `-of_modules`). If you do not specify *name_patterns*, the tool returns all root bundle objects. If the *name_patterns* is used (with `-regex` or not), the results are all sub bundle objects or leaf objects match with the specified patterns. The “/”, “.”, and “[” characters are the delimiters in the name pattern list. When the `-regex` option is used, the “.” and “[” characters, when used as delimiters, need to be escaped as those characters are meta characters in a regular expression.

See “[Bundle Object Introspection](#)” in the *Tessent Shell User’s Manual* for complete information.

- -hierarchical

An optional switch that specifies to perform pattern matching relative to all instances found below the current design. When this option is specified, the *name_patterns* argument cannot include any slash characters.

- -filter *attribute_equation*

An optional switch and string that specify to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the net object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The =~ and !~ matching operators used simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option or not.

- -regexp

An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a regular expression instead of as a simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.

- -nocase

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for nets matching the *name_patterns*.

- -silent

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This -silent option has no effect on any other error reporting.

Note

 You can use the -silent switch to manage the case in which an empty collection is returned. Before using the -silent switch for this purpose, refer to the `set_tcl_shell_options -change_no_result_warnings_to_errors` switch description for detailed usage.

Examples

Example 1

In the following example, the collection of all nets is filtered based on an *attribute_equation* of user-defined attributes.

```
get_nets -filter {MyType1 || myType2 == "AB"}
{u3_Y u4_O2}
```

Example 2

In the following example, the collection of all nets matching a list of hierarchical name patterns are returned. The names `u1/*` and `u*/u*` are only searched relative to the current design. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for an example of pattern matching with regular expressions.

```
get_nets {u1/* u*/u*}
```

```
{u4/u4_Y u4/u1_Y u4/u2_Q u5/u4_Y u5/u1_Y u5/u2_Q}
```

Example 3

In the following example, the collection of all nets matching a leaf name pattern is returned. The leaf net name `u4*` searches for all nets found below the current design.

```
get_nets u4* -hierarchical
```

```
{u4_O1 u4_O2 u4_O3 u4/u4_Y u5/u4_Y}
```

Example 4

The following example returns the net bundle objects defined by the following:

```
typedef struct packed {  
    logic f;  
} struct_t;
```

```
typedef struct_t [1:0][1:1] array_t;  
input array_t data_in [2:0]
```

```
get_nets
```

```
{data_in[2][1][1].f data_in[2][0][1].f data_in[1][1][1].f  
data_in[1][0][1].f data_in[0][1][1].f data_in[0][0][1].f}
```

```
get_nets -bundle
```

```
{data_in}
```

```
get_nets data_in[2][*][1]
```

```
{data_in[2][1][1].f data_in[2][0][1].f}
```

```
get_nets data_in[2][*][1] -bundle
```

```
{data_in[2][1][1] data_in[2][0][1]}
```

```
get_nets data_in[2][*] -bundle
```

```
{data_in[2][1] data_in[2][0]}
```

```
get_nets data_in[*][*] -bundle
```

```

get_open_pattern_set

Context: patterns -ijtag

Mode: analysis

Returns the name of the currently open pattern set.

Usage

```
get_open_pattern_set
```

Description

Returns the name of the currently open pattern set.

This command returns an empty string if no pattern set is open.

Arguments

None

Return Values

The name of the currently open pattern set.

Examples

The following example prints the name of the currently open pattern set:

```
puts "The currently opened pattern set is called [get_open_pattern_set]"
```

Related Topics

[reset_open_pattern_set](#)

get_pattern_cycle_count

Context: dft -edt, patterns -scan, patterns -scan_diagnosis, patterns -failure_mapping

Mode: analysis

Reports the total number of cycles in the currently loaded WGL or STIL test pattern set.

Usage

```
get_pattern_cycle_count
```

Description

Reports the total number of cycles in the currently loaded WGL or STIL test pattern set.

The `get_pattern_cycle_count` command reports the total number of cycles in the currently loaded test pattern set. The test pattern set must be STIL or WGL format.

Arguments

None

Examples

Example 1

The following example sets the pattern source to an external source, the *pat.wgl* file and displays the total number of cycles in the *pat.wgl* test pattern file:

```
read_patterns pat.wgl -wgl  
get_pattern_cycle_count
```

Example 2

The following example sets the pattern source to an external pattern database source, the *pat1.wgl* file, appends the *pat2.wgl* test pattern file to it, and displays the total number of cycles contained in both test pattern files:

```
read_patterns pat1.wgl  
read_patterns pat2.wgl -append  
get_pattern_cycle_count //reports total cycles for pat1 and pat2
```

Related Topics

[read_patterns](#)

get_pattern_set_data

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: analysis

Returns requested details of the internal representation of the specified pattern set.

Usage

```
get_pattern_set_data pattern_set_name [-unrolled] {-port_list | -event_list |  
-event_data event_id}
```

Description

Returns requested details of the internal representation of the specified pattern set.

The `get_pattern_set_data` command provides introspection into the internal representation of retargeted IJTAG patterns. Among other uses, this information can be used to generate pattern files for non-IJTAG compliant access mechanisms (for example, IEEE 1149.7), as long as the access hardware can produce the retargeted IJTAG patterns; that is, as long as the access mechanism does not put any restrictions on IJTAG retargeting.

Arguments

- ***pattern_set_name***

A required string that specifies the pattern set from which to introspect the requested information.

In the contexts “dft”, “patterns -scan”, “patterns -scan_diagnosis” and “patterns -scan_retargeting”, the `pattern_set_name` value can be “test_setup” and “test_end”, which represent the results of the retargeting of the corresponding test procedure iCalls.

In the context “patterns -ijtag”, the `pattern_set_name` value can be any name used by `open_pattern_set` once it has been closed.

The `pattern_set_name` value can be “ssn_setup” or “ssn_end” in the contexts “patterns -scan”, “patterns -scan_diagnosis”, and “patterns -scan_retargeting” when SSN is present in the design. Use these values after [write_patterns](#) to enable introspection into the SSN procedures.

- **-unrolled**

An optional switch that specifies to restrict the information returned when the `-event_list` or `-event_data` switches are used. The `-unrolled` switch has no effect on the `-port_list` switch. For more information on using `-unrolled` with `-event_list` and `-event_data`, refer to the descriptions of those switches below.

- **-port_list**

An optional switch that specifies to return the list of ports to which values are written or from which values are read in the specified pattern set.

- **-event_list**

An optional switch that specifies to return the list of all event identifiers of the pattern set.

When the `-event_list` switch is used without the `-unrolled` switch, the returned list contains identifiers of events of type `vector`, `scan`, `reset`, `loop`, `goto_state` or `nop`.

When the `-event_list` switch is used with the `-unrolled` switch, the returned list only contains identifiers of events of type `vector`, `loop` and `nop`. Events of type `scan`, `reset` and `goto_state` are unrolled or broken into the appropriate vector events.

See “Event Types” below for details of all the event types.

- **-event_data *event_id***

An optional switch and string pair that specifies to return a list of key/value pairs of event data. *event_id* must be a string from the list returned by “`get_pattern_set_data -event_list`”. You must first request the list of event identifiers from the pattern set, then you can use the event identifiers to get the pattern set data event by event.

Note

 It is your responsibility to ensure that the `-unrolled` switch is used consistently. The event identifiers obtained by means of “`get_pattern_set_data -event_list`” only make sense in “`get_pattern_set_data -event_data event_id`”, and the event identifiers obtained by means of “`get_pattern_set_data -unrolled -event_list`” only make sense in “`get_pattern_set_data -unrolled -event_data event_id`”. As the *event_ids* are not guaranteed to be mutually exclusive, you must be careful to use `-unrolled` consistently.

The return value of `get_pattern_set_data pattern_set_name -event_data event_id` is always a list with an even number of elements, in which the first, third, fifth ... elements represent keys and the second, fourth, sixth ... elements represent values. This convention enables the conversion into an associative Tcl array by means of the following command:

```
array set <variable name> <even-sized list>
```

Tcl enables you to iterate on a list using several variables. This is useful to iterate on the results of `get_pattern_set_data`. For example, you can do the following:

```
foreach {key value} [get_pattern_set_data test -event_data] { ... }
```

Some of the key/value pairs are guaranteed to appear in the result, others appear only if the related values exist in the retargeted patterns. The entries in the tables are flagged as “mandatory” or “optional” to reflect this.

Event Types

- A vector event represents a single parallel vector, the stimulus data of the primary inputs (or bidirectional ports) of the design and the response data of primary outputs (or bidirectional ports).

A scan event represents one scan load/unload.

A reset event represents a global reset (such as would be happen, for example, by applying a ‘0’ to the TRST port of a TAP controller).

A loop event represents a certain idle time. The vector_count in the event data refers to tester periods, potentially rounded towards the next integer.

A goto_state event represents the transition from one TAP state to another one. The paths for those transitions are the same as the default paths for TAP state transitions in SVF.

A nop event (“no operation”) represents the absence of any action. It is only required to hold the information about notes (iNotes) that have been added after the last actual action.

The type of the event can be derived from the identifier names. An event of type vector has an identifier named vector number, where number is an increasing index. An event of type scan has an identifier named scan number and so on.

The following is an example of an event list:

```
{reset0 vector0 scan0 scan1 loop0 scan2 loop1 scan3 vector1}
```

Table 4-7. Events of Type “vector”

Key	Value
port_values (mandatory)	String consisting of the characters “U”, “D”, “0”, “1”, “X”, “Z”, “M”, “P” and “-”. The order is the same as in the port list (returned by get_pattern_set_data-port_list). The meaning of the characters is as follows: D expect 0 (hint: “down”) U expect 1 (hint: “up”) M expect Z (hint: “middle” or “median”) X do not expect any specific value L drive 0 (hint: “low”) H drive 1 (hint: “high”) Z drive Z P pulse (only appears in combination with TCKPorts or capture_shift_clocks) - used for ScanInPorts, which are not involved in a scan load D, U, X, L, H and Z are the same as in SVF. IJTAG adds P, M and - to the list of possible states.

Table 4-7. Events of Type “vector” (cont.)

Key	Value
<p>write_var.port_list (optional)</p>	<p>Names of the primary input ports (or bidirectional ports), which the write_var.name_list and write_var.inversion_list specifications refer to. Each port can occur only once.</p> <p>The length of the write_var.port_list, write_var.name_list, and write_var.inversion_list lists is always the same. Use a for loop where the index goes from 0 to length-1 and lindex to extract the matching values from the three lists as shown in the example below.</p> <p>Refer to PDL Retargeting With Symbolic Variables in the <i>Tessent IJTAG User’s Manual</i> for more information on the concept of iWriteVars.</p>
<p>write_var.name_list (optional)</p>	<p>Names of iWriteVars associated with the ports. One element per port, same order as in the write_var.port_list.</p>
<p>write_var.inversion_list (optional)</p>	<p>Specifies the inversion of the iWriteVars. The elements of the list can be 0 (no inversion) or 1 (inversion). The list must contain the same number of elements as the write_var.port_list.</p>
<p>read_var.port_list (optional)</p>	<p>Names of the primary output ports (or bidirectional ports), which the read_var.name_list and read_var.inversion_list specifications refer to. Each port can occur several times, because an output port can be used to observe several targets at the same time.</p> <p>The length of the read_var.port_list, read_var.name_list and read_var.inversion_list lists is always the same. Use a for loop where the index goes from 0 to length-1 and lindex to extract the matching values from the three lists as shown in the example later in this topic.</p> <p>There is one such entry per variable bit. A read_var is inferred for each iRead whether or not there was an iNote to name the iReadVar. When there is no specified tessent_pragma iReadVar to provide a name, the name of the ICL object that was read is used as the variable name.</p> <p>Refer to PDL Retargeting With Symbolic Variables in the <i>Tessent IJTAG User’s Manual</i> for more information on the concept of iWriteVars.</p>
<p>read_var.name_list (optional)</p>	<p>Names of iReadVars associated with the ports. One element per port, same order as in the read_var.port_list.</p>

Table 4-7. Events of Type “vector” (cont.)

Key	Value
read_var.inversion_list (optional)	Specifies the inversion of the iReadVars. The elements of the list can be 0 (no inversion) or 1 (inversion). The list must contain the same number of elements as the read_var.port list.
notes.text_list (optional)	List of notes preceding this event.
notes.type_list (optional)	List of the types of the notes. The list has the same number of elements as notes.text_list. The elements can be one of “user”, “comment”, “status”, or “process”. “user”, “status” and “comment” notes are those that are generated as a result of the iNote command (with corresponding options). “process” notes are notes generated by the tool.

Table 4-8. Events of Type “scan”

Key	Value
port_values	All values except “-” have the same meaning as in “vector”. In events of type “scan”, the value “-” is used for all ScanInPorts. The actual scan load data can be found at <chain_id>.si_values. If the port_values contain expected values other than “X”, this indicates that the comparison must be done in each cycle of the scan load.
write_var.port_list write_var.name_list write_var.inversion_list notes.text_list notes.type_list	Same as in “vector”.
scan_interface (mandatory)	Name of the scan interface (as specified in ICL).
scan_type (mandatory)	“DR” or “IR”. Always “DR” for designs without TAP.
start_state (mandatory)	Start state of the TAP controller. Can be one of IDLE, DRPAUSE, or IRPAUSE. For non-TAP designs, it can be IDLE or DRPAUSE. In this case, “DRPAUSE” means that there is no capture in this scan load, while “IDLE” means that there is a capture.

Table 4-8. Events of Type “scan” (cont.)

Key	Value
end_state (mandatory)	End state of the TAP controller. Can be one of IDLE, DRPAUSE, or IRPAUSE. For non-TAP designs, it can be IDLE or DRPAUSE. In this case, “DRPAUSE” means that there is no update in this scan load, while “IDLE” means that there is an update.
chain_list (mandatory)	List of identifiers of active chains. If the active ScanInterface does not contain Chain statements, the list consists of only one single element, which is called “default”.
<chain_id>.length (mandatory)	Length of the scan chain.
<chain_id>.offset (mandatory)	The number of overshift cycles: that is, the difference between the number of shift cycles and the length of the chain.
<chain_id>.inversion (mandatory)	The chain inversion between ScanInPort and ScanOutPort.
<chain_id>.si_values (mandatory)	Scan-in value. A string consisting of “0” and “1” as wide as length+offset.
<chain_id>.so_values (mandatory)	Scan-out value. A string consisting of “0”, “1” and “X” as wide as length+offset.
<chain_id>.write_var.cycle_list (optional)	List of cycles that the <chain_id>.write_var.name_list and <chain_id>.write_var.inversion_list refer to. The cycle corresponds to the location of the bit within the scan chain where cycle 0 is the closest to the scan out. The length of the <chain_id>.write_var.cycle_list, <chain_id>.write_var.name_list and <chain_id>.write_var.inversion_list lists is always the same. Use a for loop where the index goes from 0 to length-1 and index to extract the matching values from the three lists. There is one such entry per variable bit. A write_var is inferred for each iWrite when there was an iNote to name the iWriteVar. Refer to PDL Retargeting With Symbolic Variables in the <i>Tessent IJTAG User’s Manual</i> for more information on the concept of iWriteVars.
<chain_id>.write_var.name_list (optional)	List of the names of the write_var where each bit of the variable is listed separately.

Table 4-8. Events of Type “scan” (cont.)

Key	Value
<p><chain_id>.write_var.inversion_list (optional)</p>	<p>List of inversions, consistent with cycle_list, analogously defined as write_var.inversion_list.</p> <p> Note: The inversions take the scan-in inversions into account, such that what has to be applied to the scan-in port can be derived directly.</p> <p>The length of the <chain_id>.read_var.cycle_list, <chain_id>.read_var.name_list, and <chain_id>.read_var.inversion_list lists is always the same. Use a for loop where the index goes from 0 to length-1 and lindex to extract the matching values from the three lists.</p>
<p><chain_id>.read_var.cycle_list (optional)</p>	<p>List of cycles that the <chain_id>.read_var.name_list and <chain_id>.read_var.inversion_list refer to. The cycles correspond to the location of the bits within the scan chain where cycle 0 is the closest to the scan out.</p> <p>The length of the <chain_id>.read_var.cycle_list, <chain_id>.read_var.name_list, and <chain_id>.read_var.inversion_list lists is always the same. Use a for loop where the index goes from 0 to length-1 and lindex to extract the matching values from the three lists.</p> <p>There is one such entry per variable bit. A read_var is inferred for each iRead whether or not there was an iNote to name the iReadVar. When there is no specified tesseract_pragma iReadVar to provide a name, the name of the ICL object that was read is used as the variable name.</p> <p>Refer to PDL Retargeting With Symbolic Variables in the <i>Tessent IJTAG User's Manual</i> for more information on the concept of iWriteVars.</p>
<p><chain_id>.read_var.name_list (optional)</p>	<p>List of the name of the read_var where each bit of the variable is listed separately.</p>
<p><chain_id>.read_var.inversion_list (optional)</p>	<p>List of inversions, consistent with cycle_list, analogously defined as read_var.inversion_list.</p> <p> Note: The inversions take the scan-out inversions into account, such that what has to be expected at the scan-out port can be derived directly.</p>
<p><chain_id>.register.name_list</p>	<p>The names of the ICL ScanRegisters in the correct order from scan-in to scan-out.</p>

Table 4-8. Events of Type “scan” (cont.)

Key	Value
<chain_id>.register.length_list	The list of register lengths in the order from scan-in to scan-out. The elements in this list can be mapped uniquely to the elements in the list that is referenced by <chain_id>.register.name_list.

Table 4-9. Events of Type “reset”

Key	Value
notes.text_list notes.type_list	Same as in “vector”.
sync (mandatory)	“On” or “Off”. Specifies whether a synchronous reset shall be enforced.
type (mandatory)	“user” or “process”. “user” indicates the usage of iReset, whereas “process” indicates a reset generated by the tool, for example on behalf of the open_pattern_set command (if used without no_initial_ireset).

Table 4-10. Events of Type “loop”

Key	Value
port_values write_var.port_list write_var.name_list write_var.inversion_list notes.text_list notes.type_list	Same as in “vector”. If the port_values contain expected values other than “X”, this indicates that the comparison must be done in each cycle of the loop.
vector_count (mandatory)	Duration in terms of tester periods, rounded towards the next integer.

Table 4-11. Events of Type “goto_state”

Key	Value
port_values write_var.port_list write_var.name_list write_var.inversion_list notes.text_list notes.type_list	Same as in “vector”. If the port_values contain expected values other than “X”, this indicates that the comparison must be done in each cycle of the transition.
start_state (mandatory)	IDLE, DRPAUSE or IRPAUSE.
end_state (mandatory)	IDLE, DRPAUSE or IRPAUSE.

Table 4-12. Events of Type “nop”

Key	Value
notes.text_list notes.type_list	Same as in “vector”.

Examples

The following example illustrates the usage of the get_pattern_set_data command.

```

SETUP> set_context patterns -ijtag -no_rtl

get_pattern_set_list

Context: patterns -ijtag

Mode: analysis

Returns a Tcl list of all existing and closed pattern sets in the order of their creation.

Usage

```
get_pattern_set_list
```

Description

Returns a Tcl list of all existing and closed pattern sets in the order of their creation.

The currently open pattern set is not part of the list.

Arguments

None

Return Values

A Tcl list of all existing and closed pattern sets in the order of their creation.

Examples

The following example sets the patlist variable to the set of all existing pattern sets.

```
set patlist [get_pattern_set_list]
```

Related Topics

[close_pattern_set](#)

[open_pattern_set](#)

[reset_open_pattern_set](#)

get_pattern_set_option

Context: patterns -ijtag

Mode: analysis

Returns the value of the requested option for the specified pattern_set_name.

Usage

```
get_pattern_set_option [pattern_set_name] {-timeplate_name | -tester_period | -cycles |  
-tck_ratio | -initial_ireset | -active_scan_interfaces | -network_end_state |  
-tap_start_state | -tap_end_state | -saved}
```

Description

Returns the value of the requested option for the specified pattern_set_name.

Arguments

- *pattern_set_name*
Specifies an optional pattern set name from which to introspect the specified option. When not specified, the currently open pattern set is introspected.
- **-timeplate_name**
Returns the name of the optional timeplate that was used when opening the pattern set. Returns null if the open_pattern_set -timeplate option was not specified; in this case the default timeplate is used. See [open_pattern_set](#) for a description of the default timeplate.
- **-tester_period**
Returns the tester period used by the pattern set.
- **-cycles**
Returns the complete number of tester cycles required to run the pattern set on a tester.
- **-tck_ratio**
Returns the tck_ratio value of the pattern set.
The value of tck_ratio might depend on the maximum tck clock frequency that can be applied to the circuit. See the “[IJTAG Network Performance Optimization](#)” section in the *Tessent IJTAG User’s Manual* showing how to maximize the frequency of the IJTAG network test clock.
- **-initial_ireset**
Returns 1 when the pattern set was opened without the -no_initial_ireset option; returns 0 when the option was used.
- **-active_scan_interfaces**
Returns the names of the active scan interfaces.

- **-network_end_state**
Returns keep, initial, or reset based on the value used with the `close_pattern_set` `-network_end_state` option.
- **-tap_start_state**
Returns the expected TAP start state. The possible values are: “IDLE”, “DRPAUSE”, “IRPAUSE” or “any”.
- **-tap_end_state**
Returns the established TAP end state. The possible values are: “IDLE”, “DRPAUSE”, or “IRPAUSE”. An error message is issued if you try to get the TAP end state of an open pattern set.
- **-saved**
Returns 1 when the pattern set was written out using at least one [write_patterns](#) command.
Returns 0 otherwise.

Return Values

The value of the requested option.

Examples

In the following example, the total number of cycles for pattern set P1 is stored in the Tcl variable V1.

```
set V1 [get_pattern_set_option P1 -cycles]
```

get_pin_name_list

Context: all contexts

Mode: all modes

Returns the names of the associated design pins for a given collection of ICL pins.

Usage

`get_pin_name_list -of_icl_pins icl_pins`

Description

Use this command to obtain the names of the associated design pins for a given collection of ICL pins. When the full view of the design is in memory, you can use `get_pins -of_icl_pins` to get the actual pin objects. However, if you only have a partial view of the design in memory, there may not be a pin object to return, but you may still be interested in finding the names of the design pins to feed to your SDC or simulation testbenches. If the design object is complex, such as a Verilog struct or system Interface port, the name differs between the RTL and synthesized view. The `set_context -rtl / -no_rtl` switch you used determines if the RTL or gate level name is returned. For example, the Tessent Shell tool uses this command to get the design name for ICL pins of type ClockPort to monitor those clock pins during simulation.

Arguments

- `-of_icl_pins icl_pins`

A required switch and value pair that specifies a collection of ICL pins for which the design names are required.

get_pins

Context: all contexts

Mode: all modes

Returns a collection of all hierarchical pins instantiated relative to the current design that match the specified `name_patterns` list, subject to filtering by other options.

Usage

```
get_pins [name_patterns]  
  [-direction input | output | inout]  
  [-of_instances instance_objects | -below_instances instance_objects]  
  [-of_ports port_objects  
  | -of_nets net_objects  
  | -of_gate_pin gate_pin_objects  
  | -of_pseudo_ports pseudo_port_objects  
  | -of_icl_pins icl_pin_objects  
  | -of_icl_ports icl_port_objects]  
  [-bundle]  
  [-hierarchical]  
  [-use_path_matching_options]  
  [-filter attribute_equation]  
  [-regexp]  
  [-nocase]  
  [-silent]
```

Description

Returns a collection of all hierarchical pins instantiated relative to the current design. The pins can be filtered by different properties.

Arguments

- *name_patterns*

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of pins. The string is a Tcl list of patterns separated by spaces and enclosed in braces `{}`. If no *name_patterns* are specified, the tool searches all pins.

You can use the exact RTL instance path and port names here to find the equivalent pin objects on quick synthesis views. This enables you to load a `DftSpecification` with RTL instance paths in analysis mode if the current views are quick synthesized. Use only the full names of the leaf objects. Do not use the bundle objects unless you load the `DftSpecification` with RTL views.

This argument cannot be specified with either the `-of_nets` or `-of_gate_pin` arguments.

The following limitations apply:

- You can use wildcards in *name_patterns*, but you cannot use a wildcard as part of the left or right index of a range. For example: [*** : <right_index>] is not supported.
- A range (a dimension of the form [<left_index> : <right_index>]) can only be used in the last dimension of the last field of the *name_patterns*.

See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a complete description of the pattern syntax when the `-regexp` option is used and not used.

- `-direction input | output | inout`

An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the pin object. When omitted, pins with any direction are considered.

- `-of_instances instance_objects`

An optional switch and value pair that constrains the command to search for pins on the specified *instance_objects*. When this option is specified, the optional *name_patterns* must be the name pattern of a leaf that is checked against the leaf name of the pins. An error is generated if the specified *name_patterns* contain more than one level of hierarchy when the `-of_instances` option is used. This method is more direct and efficient than traversing the *module_name* attribute because it automatically handles libraries and architectures.

- `-below_instances instance_objects`

An optional switch and value pair that constrains the command to search for pins below the specified *instance_objects*. Specified *name_patterns* are searched relative to the specified *instance_objects* when this option is used.

If the specified *instance_objects* is an empty collection, all instances below the current design are considered. See the description of the “[get_instances -below_instances](#)” command description for more information.

- `-of_ports port_objects`

An optional switch and value pair that constrains the command to return a collection of pins associated to a collection of ports. The port objects must be associated to sub-modules instantiated at any level below the current design. Ports of the current design do not have associated pins. This switch finds all instances of the associated sub-modules, then finds the pins on those instances with a *leaf_name* matching the supplied port names.

The value of this switch cannot be a Tcl list of port names because those names would only be searched on the current design.

Use the “[get_ports -of_module](#)” command to create a collection of port objects. Pass the collection to the “[get_pins -of_ports](#)” command to map the ports to pins. Use a command as shown below to map a set of ports on a sub-module to their corresponding pin objects:

```
get_pins -of_ports [get_ports {p1 p2} -of_mod ABC]
```

Using a construct such as “`get_pins -of_ports {p1 p2}`” does not work because there are no pins associated to ports of the current design.

For an example of using this switch, see the description of the “[set_insertion_options](#)” command.

- **-of_nets** *net_objects*

An optional switch and value pair that constrains the command to return the pin objects associated to *net_objects*. You cannot use a *name_patterns* list when using this option.

More than one pin can be returned for a specified net:

```
module subA (  
    .A({a2, a1, a2}),  
    .B({b3, b2, b1, b0})  
);  
    input  a1;  
    input  a2;  
    output b3, b2, b1, b0;  
endmodule  
  
module top (A, B);  
    input [2:0] A;  
    output [3:0] B;  
    subA u_A (.A(A), .B(B));  
endmodule
```

In this example, the net `u_A/a2` is associated with pins `u_A/A[2]` and `u_A/A[0]`:

```
SETUP> get_pins -of_nets {u_A/a2 u_A/b2}  
{u_A/A[0] u_A/A[2] u_A/B[2]}
```

- **-of_gate_pin** *gate_pin_objects*

An optional switch and value pair that constrains the command to return the pin objects associated with the specified *gate_pin_objects*. Given a collection or list of *gate_pin* objects, the *gate_pin* objects are mapped to the corresponding hierarchical pin objects. Any *gate_pin* object not having an associated hierarchical pin object is discarded. You cannot use a *name_patterns* list when using this option.

- **-of_pseudo_ports** *pseudo_port_objects*

An optional switch and value pair that constrains the command to return the design pins associated with the specified pseudo-ports (user-added primary inputs or outputs).

- **-of_icl_pins** *icl_pin_objects*

An optional switch and value pair that constrains the command to return the pin objects associated to the specified *icl_pin_objects*.

If the ICL attributes *tessent_design_gate_ports* and *tessent_design_rtl_ports* are defined for the ICL port of the given ICL pin, they are used to find the equivalent design pin. The value of the attributes *tessent_design_gate_ports* and *tessent_design_rtl_ports* are empty if they are the same as the ICL port name.

If you use this switch in `-no_rtl` mode after real logic synthesis, and the design footprint has changed (for example, due to bit-blasting), the value of the attribute *tessent_design_gate_ports* does not match the design objects in the current design.

The gate name mapping function finds (as with the `-use_path_matching_option`) the new equivalent port and updates the `tessent_design_gate_ports` attribute with the new value. See “[Post-Synthesis Update](#)” in the *Tessent Shell User’s Manual* for a description of this function. This attribute assignment persists, and the design pin can be successfully found with subsequent calls to `get_pins -of_icl_pins` with the same ICL pin. See the `add_rtl_to_gates_mapping` command to configure the name mapping.

In the general scenario (`-no_rtl` mode), the attribute `tessent_design_gate_ports` is updated during `set_current_design`.

- `-of_icl_ports icl_port_objects`

An optional switch and value pair that constrains the command to return the pin objects associated with the specified `icl_port_objects`. If you know the design instance associated with the specified pin objects, use the `-of_instances` or `-below_instances` switch. The ICL port objects’ association to the design pins is determined by finding an instance of the design module matching the ICL module of the ICL port.

When using the `-of_instances` or `-below_instances` options, the specified ICL ports must all exist in a single ICL module. Be certain that the ICL module of the specified ICL ports is associated with the modules of the specified instances. For computational efficiency, this association is assumed and is not verified by the tool.

The searching behavior described for the `-of_icl_pins` option is applied here to find the equivalent design port.

- `-bundle`

An optional switch that constrains the command to return pin bundle objects. When specified, the tool traverses the bundle hierarchy of all root bundle objects declared in the selected view (current design or other views selected by `-of_modules`). If you do not specify `name_patterns`, the tool returns all root bundle objects. If the `name_patterns` is used (with `-regexp` or not), the results are all sub bundle objects or leaf objects match with the specified patterns. The “/”, “.”, and “[]” characters are the delimiters in the name pattern list. When the `-regexp` option is used, the “.” and “[]” characters, when used as delimiters, need to be escaped as those characters are meta characters in a regular expression.

See “[Bundle Object Introspection](#)” in the *Tessent Shell User’s Manual* for complete information.

- `-hierarchical`

An optional switch that specifies to perform pattern matching relative to all instances found below the current design. When this option is specified, the `name_patterns` argument cannot include more than one slash.

Using “`get_pins name_pattern -hierarchical`” is a very expensive operation. Avoid using this operation on large designs. See [Example 8](#) for a better way to achieve the same result.

- **-use_path_matching_options**

An optional switch that performs pin name-mapping using rules you specified for RTL to post-synthesis/post-layout name mapping. Using this option enables you to find a pin using the instance and port mapping rules.

The following procedure is used to map the pin name: First, an attempt is made to look up the name as-is. If this is unsuccessful, an empty collection is created if the design is a quick synthesis view and “[set_context context -rtl_mode](#)” is specified or inferred. Otherwise, if in `-no_rtl` mode (after real logic synthesis), all default matching rules (instance path and port name) in the list of matching rules are applied in turn until a match is found or the rules are exhausted. User-specified name pairs are checked first, followed by the default mapping strategy, followed by any user-specified mapping expressions.

Note

User-specified rules are checked only for instance paths, not for port names.

This switch is used to find the equivalent pins after logic synthesis using the original RTL names or initial post-synthesis names. The `name_patterns` parameter cannot contain wildcards if this switch is used. If a slice is specified in no RTL mode, the returned value is a Tcl collection of multiple pin objects.

See [add_rtl_to_gates_mapping](#) for complete information.

- **-filter *attribute_equation***

An optional switch and string pair that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the pin object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The `=~` and `!~` matching operator use simple wildcard matching versus Posix extended regular expression based on the presence of the `-regexp` option.

- **-regexp**

An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a regular expression instead of as a simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.

- **-nocase**

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for pin names matching *name_patterns*.

- **-silent**

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

 You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the `set_tcl_shell_options` [-change_no_result_warnings_to_errors](#) switch description for detailed usage.

Examples**Example 1**

In the following example, the collection of all pins is filtered based on an `attribute_equation` of user-defined attributes.

```
get_pins -filter {myType1 || myType2 == "ABC"}
{u1/Y u4/u4/A0 u7/D}
```

Example 2

In the following example, the collection of all pins matching a list of hierarchical name patterns is returned. The names `u1/Y` and `u*/Q` are only searched relative to the current design. See section [“Glob and Regular Expression Pattern Matching Syntax”](#) on page 3638 for examples of pattern matching with regular expressions.

```
get_pins {u1/Y u*/Q}
{u1/Y u2/Q u7/Q}
```

Example 3

In the following example, the pins with `leaf_name` matching `Q*` and found on instances of module `DFF` are returned

```
get_pins Q* -of_instances [get_instances -of_modules DFF]
{u2/reg1/Q u2/reg1/QB u3/reg5/Q}
```

Example 4

In the following example, the collection of all pins matching a leaf instance_name/leaf pin name pattern is returned. The tool searches for the leaf instance name `u*` in all instances found below the current design, and then searches for the leaf pin names matching `Y*` on those instances.

```
get_pins u*/Y* -hierarchical
{u1/Y u3/Y u4/u1/Y u4/u4/Y u4/u5/u1/Y u5/u1/Y u5/u3/Y u5/u4/Y u6/Y}
```

Example 5

This example return the pin names of the specified `pseudo_port` objects:

```
get_pins -of_pseudo_ports {user_pi1 user_pi2}
{u1/Y u3/Y u4/Y}
```

Example 6

This example shows a small proc used to get the net or pin on which the pseudo_port was created:

```
proc get_objects_from_pseudo_ports {pseudo_port} {
  set objects {}
  append_to_collection objects [get_pins -of_pseudo_ports $pseudo_port
    -silent]
  append_to_collection objects [get_nets -of_pseudo_ports $pseudo_port
    -silent]
  return $objects
}
```

Example 7

This example shows a small proc used to get the net, pin, or port associated to a gate_pin:

```
proc get_objects_from_gate_pins {gate_pin} {
  set objects {}
  append_to_collection objects [get_pins -of_gate_pin $gate_pin -silent]
  append_to_collection objects [get_ports -of_gate_pin $gate_pin -of_type
    all -silent]
  append_to_collection objects [get_nets -of_gate_pin $gate_pin -silent]
  return $objects
}
```

Example 8

This example shows how to find all pins on instances of cell modules matching a given name list. One could have used the following:

```
get_pins -hierarchical {VSS VDD}
```

but this operation would be very slow on a large design given that every pin of every instance needs to be visited. Instead, use the following example:

```
foreach_in_collection cell_mod [get_modules -of_type cell] {
  set ports [get_ports {VSS VDD} -of_mod $cell_mod -silent]
  if {[sizeof_collection $ports] > 0} {
    set inst [get_instances -of_modules $cell_mod -silent]
    append_to_collection pins [get_pins {VSS VDD} -of_inst $inst -silent]
  }
}
```

Example 9

This example returns the pin bundle objects defined by the following:

```
typedef struct packed {
  logic f;
} struct_t;

typedef struct_t [1:0] [1:1] array_t;
input array_t data_in [2:0]

get_pins
```

get_pins

```
{u1/data_in[2] [1] [1] .f u1/data_in[2] [0] [1] .f u1/data_in[1] [1] [1] .f u1/

```

Example 10

Given the following definition:

```
typedef struct packed {
    logic [3:0] in;
    logic [1:0] out;
} EDT_t;
Input EDT_t edt_channel;
```

To load the DftSpecification before quick synthesis, use the following:

```
EdtChannelsIn(8:5) {
    port_pin_name : edt_channel.in;
}
// In Setup before quick synthesis you can
read_config_data ../edt.config
process_dft_spec EDT_setup
```

To load the DftSpecification after quick synthesis, you must write the configuration as follows:

```
EdtChannelsIn(8:5) {
    port_pin_name : edt_channel.in[3], edt_channel.in[2], edt_channel.in[1],
    edt_channel.in[0];
}
```

After quick synthesis, you can use the RTL leaf objects' full names to return the equivalent pin or port objects:

```
get_pins B1[1].B2.u1/data_in[5].ask[4].rsq
```

```
B1[1].B2.u1/data_in[31]
```

```
get_pins B1[1].B2.u1/data_in[31]
```

```
B1[1].B2.u1/data_in[31]
```

```
get_ports edt_channel.in
```

```
// (error)
```

```
get_ports edt_channel.in[2]
```

```
edt_channel[4]
```

Example 11Examples of calling `get_pins -of_icl_ports`:**Table 4-13. Calling `get_pins -of_icl_ports` in RTL Mode**

<p>In RTL mode (RTL view):</p> <pre>SETUP> get_pins -of_icl_ports \ data_in_full[35] \ -of_instances u1/u2 {{u1/u2/\data_in&full [2] [1].b}}</pre>	<p>From original RTL (extract_icl in RTL mode):</p> <pre>Module corea { // Created by ICL extraction DataInPort data_in_full[35] { Attribute tesseract_design_gate_ports = \ "{\data_in&full [35]}"; Attribute tesseract_design_rtl_ports = \ "{\data_in&full [2] [1].b}"; } ... }</pre>
<p>In RTL mode (quick synthesis view):</p> <pre>SETUP> get_pins -of_icl_ports \ data_in_full[35] \ -of_instances u1/u2 {{u1/u2/\data_in&full [35]}}</pre>	

Table 4-14. Calling `get_pins -of_icl_ports` in No RTL Mode After Synthesis

<pre>SETUP> get_pins -of_icl_ports \ data_in_full[35] \ -of_instances u1/u2 {u1/u2/data_in_full_35_}</pre>	<p>After logic synthesis:</p> <pre>Module corea { // Created by ICL extraction DataInPort data_in_full[35] { Attribute tesseract_design_gate_ports = \ "{\data_in_full_35_}"; Attribute tesseract_design_rtl_ports = \ "{\data_in&full [2] [1].b}"; } ... }</pre>
---	---

Example 12Examples of calling `get_pins -use_path_matching_options`:**Table 4-15. Calling `get_pins -use_path_matching_options` in RTL Mode**

<p>In RTL mode (RTL view)</p> <pre>SETUP> get_pins {{u1/loop[1].u2/\data_in&full [2] [1].b}} \ -use_path_matching_options {{ u1/loop[1].u2/\data_in&full [2] [1].b}}</pre>
<p>In RTL mode (quick synthesis view)</p> <pre>SETUP> get_pins {{u1/\loop[1].u2 /\data_in&full [35]}} -use_path_matching_options {{ u1/\loop[1].u2 /\data_in&full [35]}}</pre>

Table 4-16. Calling `get_pins -use_path_matching_options` in No RTL Mode After Synthesis

get_port_name_list

Context: all contexts

Mode: all modes

Returns the names of the associated design ports for a collection of ICL ports.

Usage

```
get_port_name_list -of_icl_ports icl_ports [-use_active_name]
```

Description

Use this command to obtain the names of the associated design ports for a given collection of ICL ports. When the full view of the design is in memory, you can use `get_ports -of_icl_ports` to get the actual port objects. However, if you only have a partial view of the design in memory, there may not be a port object to return, but you may still be interested in finding the names of the design ports to feed to your SDC or simulation testbenches. If the design object is complex, such as a Verilog struct or system Interface port, the name differs between the RTL and synthesized view. The `set_context -rtl / -no_rtl` switch you used determines if the RTL or gate level name is returned. For example, the Tessent Shell tool uses this command to get the design name for ICL pins of type ClockPort to monitor those clock pins during simulation.

Arguments

- **-of_icl_ports *icl_ports***

A required switch and value pair that specifies a collection of ICL ports for which the design names are required.

- **-use_active_name**

An optional switch that returns the active names. In RTL View, it returns the `tessent_design_rtl_ports` value. In quick synthesis view, it returns the `tessent_design_gate_ports` value. Use this switch only in RTL mode.

get_ports

Context: all contexts

Mode: all modes

Returns a collection of all hierarchical ports on the current design or a given module that match the specified filters.

Usage

```
get_ports [name_patterns]  
  [-of_modules module_objects]  
  [-of_nets net_objects]  
  | -of_pins pin_objects  
  | -of_gate_pins gate_pin_objects  
  | -of_icl_ports icl_port_objects  
  | -of_wrapper_scan_elements scan_element_spec ]  
  [-bundle]  
  [-direction input | output | inout]  
  [-of_type real | pseudo | all]  
  [-use_path_matching_options]  
  [-filter attribute_equation]  
  [-regexp]  
  [-nocase]  
  [-silent]
```

Description

Returns a collection of all hierarchical ports on the current design or a given module that match the specified *name_patterns* list (default: all ports) and other options.

Note

 Ports are not properly returned when the module has a parameter that specifies the size of the port, but the module is not instantiated in the design.

You can have any number of regular expressions in the name patterns list.

Arguments

- *name_patterns*

An optional string or Tcl list of strings that specifies the names of the ports to search and return. If no *name_patterns* are specified, the tool searches all ports in the current design.

You can use the exact RTL port names here to find the equivalent port objects on quick synthesis views. This enables you to load a DftSpecification with RTL port names in analysis mode if the current views are quick synthesized. Use only the leaf objects' full names. Do not use the bundle objects unless you load the DftSpecification with RTL views.

The following limitations apply:

- You can use wildcards in *name_patterns*, but you cannot use a wildcard as part of the left or right index of a range. For example: [*** : <right_index>] is not supported.
- A range (a dimension of the form [<left_index> : <right_index>]) can only be used in the last dimension of the last field of the *name_patterns*.

See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a complete description of the pattern syntax when the `-regexp` option is used and not used.

- `-of_modules` *module_objects*

An optional switch and value pair that constrains the command to return only the ports on the modules specified by *module_objects*.

- `-of_nets` *net_objects*

An optional switch and value pair that constrains the command to return the port objects associated to net_objects. You cannot use a *name_patterns* list when using this option.

More than one port can be returned for a specified net:

```
module top (
    .A({a2, a1, a2}),
    .B({b3, b2, b1, b0})
);
    input  a1;
    input  a2;
    output b3, b2, b1, b0;
endmodule
```

In this example, the net a2 is associated with ports A[2] and A[0]:

```
SETUP> get_ports -of_nets {a2 b2}
{A[0] A[2] B[2]}
```

- `-of_pins` *pin_objects*

An optional switch and value pair that constrains the command to return the ports defined on the modules that correspond to the pins specified by *pin_objects*.

You can further constrain the command to return only [Pseudo_ports](#) or only real [Ports](#) using “`-of_type pseudo | real`”; if you do not specify the `-of_type` switch, by default, the tool returns all real ports (`-of_type real`). If you use this option in conjunction with “`-of_type pseudo`”, the tool maps the pin that was added as part of the pseudo_port (user-added PI/PO [primary in put or output]) to the name of the associated pseudo_port. See “[Example 5](#)” on page 1127. If you added a user-specified primary input or output without specifying the pin name using “`add_primary_inputs -pseudo_port_name,`” the name of the pseudo_port may not always match the name of the pin specified; in this case, you can use the `-of_pins` switch to find the name of the associated pseudo_port.

You cannot use this switch with the “`-of_type all`” option. You also cannot use this switch with a *name_patterns* list.

- `-of_gate_pins` *gate_pin_objects*

An optional switch and value pair that constrains the command to return the ports associated to the `gate_pin` objects. Any `gate_pin` object not associated to a port object on the current design is ignored. You cannot use a *name_patterns* list when using this option.

- `-of_icl_ports` *icl_port_objects*

An optional switch and value pair that constrains the command to return the ports defined on a design module associated with the ICL modules of the specified *icl_port_objects*. If you know the design module associated with the specified ICL module, use the `-of_modules` switch.

When specifying the `-of_modules` switch with the `-of_icl_ports` switch, the specified ICL ports must all be on a single ICL module. When using these options, be certain that the ICL module of the specified ICL ports is associated with the specified design modules. This association is assumed and is not verified by the tool.

If the ICL attributes *tessent_design_gate_ports* and *tessent_design_rtl_ports* are defined for the ICL port of the given ICL pin, they are used to find the equivalent design port. The values of the attributes *tessent_design_gate_ports* and *tessent_design_rtl_ports* are empty if they are the same as the ICL port name.

If this switch is used in no RTL mode after logic synthesis and the design footprint has changed (for example, due to bit-blasting), the value of the attribute *tessent_design_gate_ports* does not match the design objects in the current design.

The gate name mapping function is used to find the new equivalent port and update the *tessent_design_gate_ports* attribute with the new value. See “[Post-Synthesis Update](#)” in the *Tessent Shell User’s Manual* for a description of this function. Subsequent calls to the “`get_ports -of_icl_ports`” command with the same ICL port objects find the design ports because this attribute assignment persists.

In the typical scenario (no RTL mode), the attribute *tessent_design_gate_ports* is updated during `set_current_design`.

When using the `-of_icl_ports` option without the `-of_modules` option, the search algorithm is applied on the current design module. If the `-of_modules` option is used with `-of_icl_ports`, only one module should be specified.

- `-of_wrapper_scan_elements` *scan_element_spec*

An optional switch and value pair that returns a collection of port objects isolated by the supplied `scan_element` objects. You can use this switch for dedicated and shared wrapper cells.

Note

This switch is only available in `dft -scan` context in analysis mode.

- `-bundle`

An optional switch that constrains the command to return port bundle objects. When specified, the tool traverses the bundle hierarchy of all root bundle objects declared in the

selected view (current design or other views selected by `-of_modules`). If you do not specify `name_patterns`, the tool returns all root bundle objects. If the `name_patterns` is used (with `-regexp` or not), the results are all sub bundle objects or leaf objects match with the specified patterns. The “/”, “.”, and “[]” characters are the delimiters in the name pattern list. When the `-regexp` option is used, the “.” and “[]” characters, when used as delimiters, need to be escaped as those characters are meta characters in a regular expression.

See “[Bundle Object Introspection](#)” in the *Tessent Shell User’s Manual* for complete information.

- `-direction input | output | inout`

An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the port object. When omitted, ports with any direction are considered.

- `-of_type real | pseudo | all`

An optional switch and literal pair that specifies to filter results based on the specified type of the port object. When omitted, only real design ports are considered. The option types have the following meaning:

`real` — Only real design ports ([Port](#) object type) are included in the returned collection.

`pseudo` — Only user-added pseudo ports ([Pseudo_port](#) object type) are included in the returned collection.

`all` — Both real (design) and pseudo (user-added) ports are included in the returned collection.

- `-use_path_matching_options`

An optional switch that uses a list of name mapping rules for post-synthesis and post-layout name mapping. Using this switch enables you to find a port using the port mapping rules.

The following method is used to map the port name: First, an attempt is made to look up the name as-is. If this is unsuccessful, an empty collection is created if the design is a quick synthesis view and “`set_context context -rtl_mode`” is specified or inferred. Otherwise, if in `-no_rtl` mode (after logic synthesis), all default port name matching rules are applied until a match is found or the rules are exhausted.

Note

User-specified rules are verified only for instance paths and not for port names.

This switch is used to find the equivalent design ports after logic synthesis using the original RTL names or the `post-synthesis_name` attribute in RTL mode. For complex ports, the RTL name is always a multidimensional structure. After logic synthesis, the ports are transformed to one-dimensional bus or scalar data types.

Ports in the SystemVerilog interface are blasted into several ports. The `name_patterns` argument cannot contain wildcards if this switch is used. If a slice is specified in no RTL mode, the result is a Tcl collection of multiple port objects.

See [add_rtl_to_gates_mapping](#) for complete information.

- **-filter *attribute_equation***

An optional switch and string that specifies to filter results based on the expression specified by the *attribute_equation* string. The attributes used within the equation must exist for the port object type. See “[Attribute Filtering Equation Syntax](#)” on page 3636 for more details on filtering attribute equation format. The `=~` and `!~` matching operators use simple wildcard matching versus Posix extended regular expression based on the presence of the `-regexp` option.

- **-regexp**

An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a real regular expression instead of as a simple wildcard pattern. See “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a description of the regular expression syntax.

- **-nocase**

An optional switch that directs the tool to perform case-insensitive pattern matching when looking for ports matching the *name_patterns*.

- **-silent**

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the *name_patterns* disappeared due to a change in a previous editing step. This `-silent` option has no effect on any other error reporting.

Note

You can use the `-silent` switch to manage the case in which an empty collection is returned. Before using the `-silent` switch for this purpose, refer to the “[set_tcl_shell_options -](#)” switch description for detailed usage.

Examples

Example 1

This example looks for ports on the current design whose name match `I*` or `O*`

```
get_ports {I* O*}
{I1 I2 I3 I4 I5 I6 I7 I8 O1 O2 O3}
```

Example 2

This example looks for scalar ports having one or two characters on module `ModA`.

```
get_ports {[:alnum:]{1,2}} -regexp -of_modules ModA
{ab a b}
```

Example 3

This example return ports based on the option specified for the `-of_type` switch:

```

add_primary_input -internal inst1/Y inst1/Z -pseudo_port_name user_pi1
add_primary_input -internal inst2/Y -pseudo_port_name user_pi2
get_ports
{port1 port2 port3}

get_ports -of_type real
{port1 port2 port3}

get_ports -of_type pseudo
{user_pi1 user_pi2}

get_ports -of_type all
{port1 port2 port3 user_pi1 user_pi2}

get_pins -of_pseudo_ports user_pi1
{inst1/Y inst1/Z}

get_pins -of_pseudo_ports user_pi2
{inst2/Y}

get_pins -of_pseudo_ports {user_pi1 user_pi2}
{inst1/Y inst1/Z inst2/Y}

```

Example 4

This example returns the `pseudo_ports` associated with the user-specified primary inputs and primary outputs based on the option specified for the `-of_type` switch:

```

add_primary_input -internal inst1/Y inst1/Z -pseudo_port_name user_pi1
add_primary_input -internal inst2/Y

get_ports -of_pins inst1/Y
{Y}

get_ports -of_pins {inst1/Y inst1/Z} -of_type real
{Y Z}

get_ports -of_pins inst1/Y -of_type pseudo
{user_pi1}

get_ports -of_pins inst2/Y -of_type real
{Y}

get_ports -of_pins inst2/Y -of_type pseudo

```

```
{inst2/Y}

get_ports -of_pins {inst1/Y inst1/Z inst2/Y} -of_type pseudo

{user_pi1 user_pi1 inst2/Y}
```

Example 5

This example returns the port bundle objects defined by the following:

```
typedef struct packed {
    logic f;
} struct_t;

typedef struct_t [1:0] [1:1] array_t;
input array_t data_in [2:0]

get_ports

{data_in[2] [1] [1] .f data_in[2] [0] [1] .f data_in[1] [1] [1] .f
data_in[1] [0] [1] .f data_in[0] [1] [1] .f data_in[0] [0] [1] .f}

get_ports -bundle

{data_in}

get_ports data_in[2][*][1]

{data_in[2] [1] [1] .f data_in[2] [0] [1] .f}

get_ports data_in[2][*][1] -bundle

{data_in[2] [1] [1] data_in[2] [0] [1] }

get_ports data_in[2][*] -bundle

{data_in[2] [1] data_in[2] [0] }

get_ports data_in[*][*] -bundle

{data_in[2] [1] data_in[2] [0] data_in[1] [1] data_in[1] [0] data_in[0] [1]
data_in[0] [0] }

get_ports data_in[*] -bundle

{data_in[2] data_in[1] data_in[0] }

get_ports data_in[2][*][1].* -bundle

{data_in[2] [1] [1] .f data_in[2] [0] [1] .f}

get_ports data_in[2][*][*].* -bundle

{data_in[2] [1] [1] .f data_in[2] [0] [1] .f}

get_bundle_objects -of_objects [get_ports data_in[2] -bundle]

{data_in[2] [1] data_in[2] [0] }

get_bundle_objects -of_objects [get_ports data_in[2] -bundle] -leaf
```

get_ports

```
{data_in[2][1][1].f data_in[2][0][1].f}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -leaf
```

```
{data_in[2][1][1].f data_in[2][0][1].f}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -children
```

```
{data_in[2][1][1] data_in[2][0][1]}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -parent
```

```
{data_in[2] data_in[2]}
```

```
get_bundle_objects -of_objects [get_ports data_in[2][*] -bundle] -root
```

```
{data_in data_in}
```

Example 6

Given the following definition:

```
typedef struct packed {
    logic [3:0] in;
    logic [1:0] out;
} EDT_t;
Input EDT_t edt_channel;
```

To load the DftSpecification before quick synthesis, use the following:

```
EdtChannelsIn(8:5) {
    port_pin_name : edt_channel.in;
}
// In Setup before quick synthesis you can
read_config_data ../edt.config
process_dft_spec EDT_setup
```

To load the DftSpecification after quick synthesis, you must write the configuration as follows:

```
EdtChannelsIn(8:5) {
    port_pin_name : edt_channel.in[3], edt_channel.in[2], edt_channel.in[1],
    edt_channel.in[0];
}
```

After quick synthesis, you can use the RTL leaf objects' full names to return the equivalent pin or port objects:

```
get_pins B1[1].B2.u1/data_in[5].ask[4].rsq
```

```
B1[1].B2.u1/data_in[31]
```

```
get_pins B1[1].B2.u1/data_in[31]
```

```
B1[1].B2.u1/data_in[31]
```

```
get_ports edt_channel.in
```

```
// (error)

get_ports edt_channel.in[2]

edt_channel [4]
```

Example 7

Examples of calling get_ports -of_icl_ports:

Table 4-20. Calling get_ports -of_icl_ports in RTL Mode

<p>In RTL mode (RTL view):</p> <pre>SETUP> get_ports -of_icl_ports \ data_in_full[35] \ {{\data_in&full [2] [1].b}}</pre>	<p>From original RTL (extract_icl in RTL mode):</p> <pre>Module top { // Created by ICL extraction DataInPort data_in_full[35] { Attribute tesseract_design_gate_ports = \ "{\data_in&full [35]}"; Attribute tesseract_design_rtl_ports = \ "{\data_in&full [2] [1].b}"; } ... }</pre>

get_procfile_name

Context: all contexts

Mode: all modes

Returns the name of the procfile that was defined using the `set_profile_name` command.

Usage

`get_procfile_name`

Description

Returns the name of the procfile that was defined using the `set_profile_name` command.

Arguments

None

Return Values

The name of the procfile as it was specified to the `set_procfile_name` command.

Examples

In the following example, the path to the specified procfile name is stored in a Tcl variable.

```
set proc_file [get_procfile_name]
```

Related Topics

[set_profile_name](#)

get_read_verilog_option

Context: unspecified, all contexts

Mode: all modes

Returns the options specified with the `set_read_verilog_options` command.

Usage

```
get_read_verilog_option -allow_enum_relaxation | -vcs_compatibility  
| -unbalanced_celldefine_severity | -strict_default_nettype_checks | -max_for_loop_size
```

Description

Returns the options specified with the `set_read_verilog_options` command.

Arguments

- `-allow_enum_relaxation`
An option that returns a 1 if “`set_read_verilog_options -allow_enum_relaxation`” is set to “on”. Otherwise, the option returns 0.
- `-vcs_compatibility`
An option that returns a 1 if “`set_read_verilog_options -vcs_compatibility`” are set to “on”. Otherwise, the option returns 0.
- `-unbalanced_celldefine_severity`
An option that returns “error” if “`set_read_verilog_options -unbalanced_celldefine_severity`” is set to error. The option returns “warning” if the switch is set to warning.
- `-strict_default_nettype_checks`
An option that returns a 1 if “`set_read_verilog_options -strict_default_nettype_checks`” is set to “on”. Otherwise, the option returns 0.
- `-max_for_loop_size`
An option that returns the maximum number of for loop iterations defined by the `set_read_verilog_options` command. The default size is 5000.

get_resource

Context: unspecified, all contexts

Mode: all modes

Returns true when all resources in the specified `resource_list` are available.

Usage

`get_resource` *resource_list*

Description

Returns true when all resources in the specified `resource_list` are available.

You use this command inside your Tcl procs to check for the availability of resources and take appropriate action when they are missing. For example, you can choose to issue the `create_flat_model` command if your command depends on it and it is not yet available.

Arguments

- *resource_list*

A Tcl list of strings that contains any of the following resource names:

`design_is_elaborated`

Used to check that the hierarchical data model has been created using the `set_current_design` command.

`design_modules_exist`

Used to check that at least one Verilog or VHDL module exists in memory and can be accessed using the `get_modules` command.

`flat_model_exists`

Used to check that the flat data model is available. The flat data model was created by either the `create_flat_model` command or by the “`set_system_mode analysis`” command.

`icl_is_elaborated`

Used to check that the ICL hierarchical data model exists. It exists after the `set_current_design` command if an ICL module corresponding to the current design existed prior to issuing the command. It also exists in the analysis mode if the top-level ICL module was successfully extracted with `ICL extract`.

`icl_modules_exist`

Used to check that at least one ICL module exists in memory and can be accessed using the `get_icl_modules` command.

`rtl_mode_enabled`

Used to check that the `-rtl` option switch was used when specifying the context and that read-in Verilog and VHDL files can contain RTL constructs.

Examples

The following example checks that both design and ICL modules exist.

```
if ![get_resource {design_modules_exist icl_modules_exist}] {  
    return -code error "you must first read in design and icl modules \  
        before running this command"  
}
```

get_run_synthesis_options

Context: unspecified

Mode: all modes

Returns the values for options that can be set for the run_synthesis command.

Usage

```
get_run_synthesis_options {[-default_synthesis_tool | -synthesis_output_directory]
  | [synthesis_tool [-compilation_options | -pre_compilation_commands
  -post_compilation_commands | -startup_file | -command_name]]}
  [-get_dictionary]
```

Description

Returns the default values for options that can be set for [run_synthesis](#) command. The options defined with [set_run_synthesis_options](#) are overridden if they are explicitly defined with the run_synthesis command.

Arguments

- `-default_synthesis_tool | -synthesis_output_directory`
 - `-default_synthesis_tool`

Returns the default synthesis tool previously set by the [set_run_synthesis_options](#) command. The default is 'dc_shell'.
 - `-synthesis_output_directory`

Returns the synthesis output directory path. The default directory is *synthesis_outdir* and is located in the Tessent Shell invocation directory.

- ***synthesis_tool***

A required value that specifies the synthesis tool when requesting a single tool-specific option. Possible values for *synthesis_tool* are:

dc_shell

genus

The tool-specific options that require this switch are:

- `-compilation_options`
- `-pre_compilation_commands`
- `-post_compilation_commands`
- `-startup_file`
- `-command_name`

- **-compilation_options**
Returns the option list that adds additional options to the synthesis compile command used in the `<synthesis_tool>.synthesis_tcl`.
- **-pre_compilation_commands**
Returns the command list that is added before the compile command in the `<synthesis_tool>.synthesis_tcl`.
- **-post_compilation_commands**
Returns the command list that is added after the compile command in the `<synthesis_tool>.synthesis_tcl`.
- **-startup_file**
Returns file path that enables you to explicitly specify the startup file that is used by synthesis.
- **-command_name**
Defines the command name to invoke the synthesis tool. The default is `dc_shell`.
- **-get_dictionary**
Returns all set synthesis options as a Tcl 'dict'.

Examples

The following are examples of the `get_run_synthesis_options` using various options.

Example 1

This example returns the default `pre_compilation_commands`:

```
INSERTION> get_run_synthesis_options dc_shell -pre_compilation_commands \  
optimize_registers
```

Example 2

This example returns the default compilation options:

```
INSERTION> get_run_synthesis_options dc_shell -compilation_options \  
-map_effort high
```

get_scan_chain_families

Context: dft -scan

Mode: analysis

Gets scan chain families with certain characteristics.

Usage

```
get_scan_chain_families [name_patterns]  
    [ -regexp ]  
    [ -nocase ]
```

Description

Use this command to get scan chain families with certain characteristics.

Arguments

- *name_patterns*
An optional list that enables returning scan chain families by their name or name pattern.
- -regexp
An optional switch that enables returning scan chain families by regular expression matching.
- -nocase
An optional switch that ignores character casing during matching.

Related Topics

[delete_scan_chain_families](#)

get_scan_chain_option

Context: pattern -scan

Mode: setup, when LBIST is on

Returns the setting of an option specified in the set_scan_chain_options command.

Usage

```
get_scan_chain_option {-chain_name chain_name... | -INStance instance_name  
-Block_chain_index_list block_chain_index_list ...}  
[-decompressor_to_scan_in_inversion | -scan_out_to_compactor_inversion ]
```

Description

Returns the setting of an option specified in the set_scan_chain_options command.

Arguments

- **-chain_name***chain_name*...
Required switch and repeatable string that specifies the name of a scan chain in the current design.
- **-INStance** *instance_name* **-Block_chain_index_list** *block_chain_index_list*...
Required set of switches and values that specifies a core instance and the list of chain indices starting with “1” on the EDT controller. When this is used, the masking applied to the specified chain is OX. Use this option in conjunction with the -USed_chains switch.
- **-decompressor_to_scan_in_inversion**
An optional Boolean switch that returns 1 when the option was explicitly set with the set_scan_chain_options command; otherwise a 0 is returned.
- **-scan_out_to_compactor_inversion**
An optional Boolean switch that returns 1 when the option was explicitly set with the set_scan_chain_options command; otherwise a 0 is returned.

Examples

Suppose you specified the following command:

```
set_scan_chain_options -chain_name chain3 -decompressor_to_scan_in_inversion on  
-scan_out_to_compactor_inversion on
```

The get_scan_chain_option would return the following values:

```
get_scan_chain_option -chain_name chain3 -decompressor_to_scan_in_inversion  
1  
  
get_scan_chain_option -chain_name chain3 -scan_out_to_compactor_inversion  
1
```

get_scan_elements

Context: dft (with no sub-context), dft -scan, dft -test_points

Mode: setup, analysis, insertion

Returns a collection of scan elements that the tool has identified in the design.

Usage

```
get_scan_elements [name_patterns]  
  [-regexp]  
  [-nocase]  
  [-silent]  
  [-of_modules obj_spec ]  
  [-of_instances obj_spec | -below_instances obj_spec]  
  [-of_child_scan_modes child_mode_names]  
  [-of_scan_modes obj_spec]  
  [-of_pins of_pin_objects]  
  [-of_chain_families of_chain_families]  
  [-of_gate_pins of_gate_pins ]  
  [-of_wrapped_ports port_spec ]  
  [{-below_scan_elements elements [-flat] | -above_scan_elements elements} [-hierarchical]]  
  [-class {core | standard | wrapper}]  
  [-states {ignored | unusable | unusable_child_mode | unresolved_child_mode | usable |  
    usable_indirectly | any_state}...]  
  [-types { chain | inferred | leaf_cell | segment | shift_register | transparent_leaf_cell |  
    combinational_leaf_cell | any_type}...]  
  [-filter attribute_equation ]
```

Description

Returns a collection of scan elements that the tool has identified in the design. Scan element can be a scan chain, a scan segment, a shift register, or leaf node. By default, the command only returns segment and leaf_cell elements. For more information, see [Scan Element Object Type](#).

See the following sections in the *Tessent Scan and ATPG User's Manual* for usage examples:

- [Scan Insertion Flow Steps](#)
- [Chain Port Sharing](#)
- [Scan Mode](#)

Arguments

- *name_patterns*
An optional list that enables returning scan elements by their name or name pattern.

get_scan_elements

- **-regexp**
An optional switch that enables returning scan elements by regular expression matching.
- **-nocase**
An optional switch that ignores character casing during matching.
- **-of_modules *obj_spec***
An optional switch and value pair that gets the scan elements that are on and below all the instances of the given module or modules.
- **-silent**
An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a possible mistake when specifying patterns. This **-silent** option has no effect on any other error reporting.

Note

 You can use the **-silent** switch to manage the case in which an empty collection is returned. Before using the **-silent** switch for this purpose, refer to the “[set_tcl_shell_options -](#)” switch description for detailed usage.

- **-of_instances *obj_spec***
An optional switch and value pair that gets the scan elements that are on the given instance or instances.
- **-below_instances *obj_spec***
An optional switch and value pair that gets the scan elements that are below the given instance or instances.

If the specified *obj_spec* is an empty collection, all instances below the current design are considered. See the description of the of the “[get_instances -below_instances](#)” command description for the justification of this behavior.
- **-below_scan_elements *elements***
An optional switch and value pair that gets the scan elements that are inside the given hierarchical scan element or elements.
- **-above_scan_elements *elements***
An optional switch and value pair that gets the parent scan elements of the scan element or elements.
- **-of_child_scan_modes *child_mode_names***
An optional switch and value pair that gets the existing segments declared with the given mode or modes.

- `-of_scan_modes obj_spec`
An optional switch and value pair that gets the scan elements that are included in the given mode or modes, previously added with the command `add_scan_mode`. This switch is only meaningful after issuing the `analyze_scan_chains` command.
- `-of_pins of_pin_objects`
An optional switch and value pair that gets the `scan_elements` associated with the specified instance pins. Specified pins can be pins on scan element leaves or existing segment connection pins.
- `-of_chain_families of_chain_families`
An optional switch and value pair that gets the scan elements that are included in the given chain families, previously added with the command `create_scan_chain_family`.
- `-of_gate_pins of_gate_pins`
An optional switch and value pair that gets the scan elements that contain the specified flat model gate pin or pins.
- `-of_wrapped_ports port_spec`
An optional switch and value pair that gets a collection of wrapper `scan_elements` that isolate the supplied ports. You can use this switch for dedicated and shared wrapper cells.

Note

This switch is only available in `dft -scan` context in analysis mode.

- `-flat`
An optional switch that recursively traverses the local hierarchies and returns only the leaf scan elements below the parent or parents.
- `-hierarchical`
An optional switch that recursively traverses the local hierarchies and returns all encountered scan elements below the parent or parents.
- `-class {core | standard | wrapper}`
An optional switch that returns only the scan elements of the specified class.

The possible classes are:

standard — Cell class of all elements when no wrapper analysis has been performed.

core — Cell class of all internal elements once the wrapper analysis has been performed.

wrapper — Cell class of all external elements once the wrapper analysis has been performed.

- `-states {ignored | unusable | unusable_child_mode | unresolved_child_mode | usable | usable_indirectly | any_state}...`

An optional switch that returns only the scan elements of the specified state. By default, only scan elements that have a state “usable” are returned. To introspect scan elements that have other states, use the `-state` option. See the example below for usage of “`-state usable_indirectly`” and “`-state ignored`”.

The possible states are:

`ignored` — Scan elements ignored for scan insertion purposes.

`unusable` — Scan elements that cannot be specified in a population for distribution purposes.

`unusable_child_mode` — Scan elements that cannot be specified in a population for distribution purposes because the necessary “`active_child_scan_mode`” attribute is not set appropriately.

`unresolved_child_mode` — Scan elements that cannot be specified in a population for distribution purposes because the “`active_child_scan_mode`” was not set and cannot be inferred.

`usable` — Scan elements that can be specified in a population for distribution purposes.

`usable_indirectly` — Usable scan elements that cannot be specified directly in a population for distribution purposes because they are part of a usable hierarchical container, which must be used instead.

`any_state` — Scan elements of all states.

- `-types { chain | inferred | leaf_cell | segment | shift_register | transparent_leaf_cell | combinational_leaf_cell | any_type}...`

An optional, repeatable switch that returns only the scan elements of the specified type or types.

The possible types are:

`chain` — Existing chains and new allocated chains that were created by distribution.

`inferred` — Hierarchical scan elements allocated by the tool during distribution.

`leaf_cell` — Scan elements from a cell library.

`segment` — Existing segments or new virtual segment created by the user.

`shift_register` — Shift-register scan arrangement identified by the tool.

`transparent_leaf_cell` — Transparent cells (for example, lockup cell) traced inside existing chains or segments that have a scan length of zero.

`combinational_leaf_cell` — Combinational cells (for example, OR-gate) traced inside existing chains or segments.

`any_type` — Scan elements of all types.

- *-filter attribute_equation*

An optional switch and value pair that returns only the scan elements that satisfy the provided attribute equation.

Examples

This example illustrates how to get the traced scan elements inside a scan segment by using the “-state usable_indirectly” option. When you omit this option, the command does not return any of the child elements of the segment, because only their parent segment is “usable”.

The example also shows how to identify scan elements that you have marked as non-scan using the “-state ignored” option.

```
> add_scan_segments subch1 -clock_pins clk1 -scan_enable_pin sen -on_module S \  
  -so_connections so1 -si_connections si1> add_scan_segments subch2 -clock_pins clk2 -  
scan_enable_pi sen -on_module S \  
  -so_connections so2 -si_connections si2> add_nonscan_instances /uA1>  
set_system_mode analysis  
> report_scan_elements
```

get_scan_elements

get_scan_modes

Contest: dft -scan

Mode: analysis, insertion

Returns the scan modes with certain characteristics.

Usage

```
get_scan_modes [name_patterns]
```

Description

Use this command to get scan modes of the current design with certain characteristics.

Arguments

- *name_patterns*
An optional list that retrieves all scan modes by their name. If no *name_patterns* are specified, all scan modes are returned.

Related Topics

[add_scan_mode](#)

[delete_scan_modes](#)

get_scratch_directory

Context: unspecified, all contexts

Mode: all modes

Returns the absolute path to the *scratch* directory.

Usage

```
get_scratch_directory
```

Description

Returns the absolute path to the *scratch* directory.

During invocation, the tool creates the *scratch* directory in the temporary directory using the following syntax:

```
.tessent.tmp.username.hostname.process_id
```

When you exit, the tool deletes this *scratch* directory.

By default, it stores the scratch directory in the location identified by the TMPDIR environment variable. If you have not defined the TMPDIR environment variable, the tool creates the scratch directory in the */tmp* directory or in the current directory if the */tmp* directory is not available.

You can explicitly specify the location where the temporary *.tessent.tmp.username.hostname.process_id* directory is created by setting the TESSENT_TMP_LOCATION environment variable. The tool creates the temporary *.tessent.tmp.username.hostname.process_id* directory in the default location if the location specified by the TESSENT_TMP_LOCATION environment variable does not exist, is not a valid directory, or does not have write permission. The tool uses the TESSENT_TMP_LOCATION environment variable when both TMPDIR and TESSENT_TMP_LOCATION exist.

Arguments

None

Examples

Suppose TMPDIR points to */home/mydir*. The following example reports the location of the *scratch* directory:

```
get_scratch_directory
```

```
/home/mydir/.tessent.tmp.user1.myhostname.28140/scratch
```

get_silicon_insight_job_status

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Returns the status of diagnosis jobs that are running in the background.

Usage

```
get_silicon_insight_job_status [-job_handle job_handle] [-display {active | all | completed}]  
[-message_type {screen_only | info}]
```

Description

You can use this command when running diagnosis on an ATPG instrument and have specified off for the wait_for_diagnosis_result configuration debug option.

Arguments

- `-job_handle job_handle`
An optional switch and string pair that specifies to return the “Running” or “Completed” status of the specified job. The specified job handle is the job ID that the tool uses when it submits a job.
- `-display {active | all | completed}`
An optional switch and string pair that specifies the status type to display as a list. The choices are:
 - all — displays all jobs.
 - active — displays the actively running jobs.
 - complete — displays the completed jobs.
- `-message_type {screen_only | info}`
An optional switch and string pair that specifies to display the status only on-screen (the default) or both on-screen and in the transcript.

Examples

```
get_silicon_insight_job_status -display active
```

```
JOB: 'all_cores_c1_2.3/job_script.sh' completed.
```

get_silicon_insight_option

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Returns current settings of options specified in the set_silicon_insight_option command.

Usage

```
get_silicon_insight_option [-cdp_verification {on | off}] [-interactive_ijtag] [-current_cdp]
[-simdut_port] [-ignore_uncontacted_pin_data {off | on}] [-interactive_ijtag_pattern_type
{svf | stil}] [-maximum_failing_cycles number]
```

Arguments

- -cdp_verification { on | off }
An optional switch that specifies whether to verify that new test patterns added as part of a test were generated by Tessent tools, which means they contain a signature that links them to the design they were generated for. The default is “on.” You may want to turn CDP verification off if you are adding test patterns that were not generated by Tessent tools.
- -interactive_ijtag
An optional switch that returns “on” or “off”.
- -current_cdp
An optional switch that returns the current CDP.
- -simdut_port
An optional switch that returns the name of the SimDUT port.
- -ignore_uncontacted_pin_data {off | on}
An option switch and string pair that specifies whether to display or ignore uncontacted pin data.
- -interactive_ijtag_pattern_type {svf | stil}
An optional switch and string pair that returns either the SVF or STIL pattern type.
- -maximum_failing_cycles *number*
An optional string and integer that specifies to display the specified number of maximum failing cycles.

get_simdut_data

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Returns information about specified design objects within designs simulated by SimDUT.

Usage

```
get_simdut_data -value_type { value | type | regs | nets | modules } object_name
```

Arguments

- **-value_type**

A required switch and literal pair that specifies the information to return about the specified design object. The choices are:

value — Value of the specified register, net, net array, or register array.

type — Type of object, where the type can be:

Reg — Register

Net — Net

Module — Module

Array Reg[*array_size*] — Register array

Array Net[*array_size*] — Net array

regs — List of registers for the specified module. You can only use this literal when you specify a module for the object name.

nets — List of nets that the specified module contains. You can only use this literal when you specify a module for the object name.

modules — List of modules that the specified module contains. You can only use this literal when you specify a module for the object name.

- *object_name*

A required literal that specifies a design object.

Description

Use this command to introspect nets, registers, and module instances within designs simulated by SimDUT. For more information, refer to “[Simulating Desktop, ATE, and ATPG Behavior](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

Examples

The following example returns the registers associated with the SIMDUT_TB.DUT_inst.block4_I1 module.

```
set result [get_simdut_data -value_type regs SIMDUT_TB.DUT_inst.block4_I1]
puts $result
sel_shiftreg[0:1] sel_nr enB enC enD enE enF selA selB art art2 art3[4:0] [3]
art4[20]
```

get_simulation_context_list

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Returns the available simulation contexts in a Tcl list.

Usage

```
get_simulation_context_list [-predefined | -user_defined]
```

Description

Returns the available simulation contexts in a Tcl list.

The `get_simulation_context_list` command returns all simulation contexts or returns only predefined or user-defined. If you issue the command without arguments, the command returns all simulation contexts. Note that for predefined simulation contexts, this command returns only the simulation contexts for which simulation data currently exists. This requires that the tool first read a procedure file.

Arguments

- `-predefined`
An optional switch that specifies predefined simulation contexts, which are listed in [Table 6-8](#) on page 2291.
- `-user_defined`
An optional switch that specifies user-defined simulation contexts.

Examples

The following example shows the Tcl list of values returned by the `get_simulation_context_list` command:

```
ANALYSIS> set_current_simulation_context stable_load_unload
ANALYSIS> add_simulation_context myContext1
ANALYSIS> add_simulation_context myContext2
ANALYSIS> get_simulation_context_list

{ stable_after_setup stable_load_unload stable_capture stable_shift
  myContext1 myContext2 }

ANALYSIS > get_simulation_context_list -user_defined

{ myContext1 myContext2 }

ANALYSIS > get_simulation_context_list -predefined

{ stable_after_setup stable_load_unload stable_capture stable_shift }
```

get_simulation_library_sources

Context: unspecified, all contexts

Mode: all modes

Returns the pathnames or file extensions previously specified with the `set_simulation_library_sources` command.

Usage

```
get_simulation_library_sources [-path_list | -extension_list | -sv_extension_list  
| -logical_library_map_list | -include_directory_list | -f_files]
```

Description

Returns the pathnames or file extensions previously specified with the [set_simulation_library_sources](#) command.

By default, the `get_simulation_library_sources` command returns a list of paired values that specify the pathnames to file and directory names. The first item in the pair is `-v` or `-y` to indicate whether the pathname is a file or a directory, respectively. This is useful when you want to add additional simulation library sources, because any invocation of the `set_simulation_library_sources` command overwrites previous invocation settings.

Arguments

- `-path_list`

An optional switch that specifies to return the list of simulation library source paths with directory and filenames. Each name is associated with a `-y` and `-v` element to identify whether the path is a directory or filename. This switch is inferred when no other switch is specified.

You can modify this returned list and feed it back to the `set_simulation_library_sources` command as shown below. The use of the `{*}` syntax is a Tcl 8.5 feature that converts the returned lists as string arguments.

```
set_simulation_library_source {*} [get_design_source -path_list] \  
{*} [get_design_source -ext_list]
```

- `-extension_list`

A Boolean switch that specifies to return the list of extensions that was used to search the library directory for the specified format.

- `-sv_extension_list`

A Boolean switch the specifies to return the list of SV extensions that was specified using the [set_simulation_library_sources](#) command.

- `-logical_library_map_list`

A Boolean switch that specifies to return the list of library directory pairs that was specified using the [set_simulation_library_sources](#) command.

- **-include_directory_list**
A Boolean switch that specifies to return the list of `include` file directory pairs that were specified with the [set_simulation_library_sources](#) command.
- **-f_files**
A Boolean switch that specifies to return a list of one or more ASCII files that contain pointers to design files that were specified using the [set_simulation_library_sources](#) command.

Examples

This example specifies information about simulation library sources, and then introspects the list of pathnames and the list of extensions specified:

```
SETUP> set_simulation_library_sources -v lib1.v lib2.v -y /u/joe/lib3 -extensions .v
SETUP> get_simulation_library_sources -path_list

-v lib1.v -v lib2.v -y /u/joe/lib3

SETUP> get_simulation_library_sources -extension_list

.v .v.gz
```

[report_simulation_library_sources](#)
[set_simulation_library_sources](#)

get_simulation_option

Context: all contexts

Mode: all modes

Returns the values for options that can be set for the `set_simulation_options` command.

Usage

```
get_simulation_option
  -set_reset_dominates_clock
  | -c6_mask_races
  | -multicycle_fault_simulation
  | -mux_select_x_sim_x
  | -feedback_buffer_x_init_value
  | -report_x_capturing_cells
  | -simulate_learned_sequential_tie_gates
  | -OBS_SCAN_PER_cycle_data_limit
  | -OBS_SCAN_LAST_shift_cycles
```

Description

Returns the values for options that can be set for the `set_simulation_options` command.

This command takes one argument at a time and returns a 0 or a 1.

Arguments

- `-set_reset_dominates_clock`
A switch that instructs the tool to return the setting for the `set_simulation_options` command that controls whether the set or reset port dominates the clock assertion value for both flip-flops and latches when multiple ports are on simultaneously. Possible return values are 0 (off) or 1 (on).
- `-c6_mask_races`
A switch that instructs the tool to return the `set_simulation_options` command setting of the pessimistic simulation on C6 violated state elements and mask the capture values only when the data port transitions at the same frame the clock port captures option. Possible return values are 0 (off) or a 1 (on).
- `-multicycle_fault_simulation`
A switch that instructs the tool to return the `set_simulation_options` command setting of the multi-cycle path ATPG and fault simulation option. Possible return values are 0 (off) or a 1 (on).
- `-mux_select_x_sim_x`
A switch that instructs the tool to return the `set_simulation_options` command setting of the `model_mux` primitives in the design as either consensus or non-consensus option. Possible return values are 0 (off) or a 1 (on).

- **-feedback_buffer_x_init_value**
A switch that instructs the tool to return the `set_simulation_options` command setting of the `FB_BUF` primitive to carry over its value from the previous cycle instead of being initialized to X option. Possible return values are 0 (off) or a 1 (on).
- **-report_x_capturing_cells**
A switch that instructs the tool to return the `set_simulation_options` command setting of the option that reports scan cells that capture X during simulation. Possible return values are 0 (off) or a 1 (on).
- **-simulate_learned_sequential_tie_gates**
A switch that instructs the tool to return the `set_simulation_options` command setting of the change the ATPG simulator behavior for sequential gates learned as tied during DRC option. Possible return values are 0 (off) or a 1 (on).
- **-OBS_SCAN_PER_cycle_data_limit**
A switch that instructs the tool to return the `set_simulation_options` command setting of the default maximum number of patterns for which the tool stores per-cycle data (that the tool can monitor for debugging purposes).
- **-OBS_SCAN_LAST_shift_cycles**
A switch that instructs the tool to return the `set_simulation_options` command setting of the number of shift cycles simulated in the parallel test bench.

[set_simulation_options](#)

get_simulation_value_list

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Returns a Tcl list of the simulation values on the specified gate_pin objects.

Usage

```
get_simulation_value_list obj_spec
```

Description

Returns a Tcl list of the simulation values on the specified gate_pin objects.

The get_simulation_value_list command returns the simulation values on the specified gate_pin objects in the current simulation context. The simulation value of a single gate_pin is either X, 0, 1, or Z.

Arguments

- *obj_spec*

A required value that specifies one or more gate_pin objects or pins that map to gate_pin objects (on library cell boundaries or preserved design boundaries).

Examples

The following example shows that the get_simulation_value_list command is equivalent with querying the simulation_value attribute. However, note that get_attribute_value_list command requires a Tcl list of gate_pins in order to work correctly, as shown in the example:

```
set_current_simulation_context stable_after_setup  
get_simulation_value_list {pi clk an_2/A0 an_2/Y}
```

```
1 X 1 X
```

```
get_attribute_value_list [get_gate_pins {pi clk an_2/A0 an_2/Y}] -name simulation_value
```

```
1 X 1 X
```

get_single_attribute_value

Context: unspecified, all contexts

Mode: all modes

Retrieves the value of an attribute on the specified design object.

Usage

get_single_attribute_value *object_spec* **-name** *attribute_name* [-is_specified]

Description

This command is the same as the [get_attribute_value_list](#) command except the *object_spec* must be a collection with exactly one element, otherwise the tool issues an error.

The return value is a single value.

Arguments

- ***object_spec***

A required value that specifies a collection of exactly one element.

It is also legal to supply a Tcl list of one object name, although this is not recommended for the following reasons:

- Objects of different types can have the same name, which can lead to confusion.
- Objects found may not support the requested attribute, which can generate an error.
- For types that accept escaped identifiers, using such a name may not find the object at all. For example, using an escaped port name like `{\nport }` with “get_single_attribute_value [list {\nport }] ...]” finds nothing. This is because escaping is not necessary for a port name that is valid without escaping. For that specific example, you should use “get_ports [list {\nport} -use_path_matching_options”, and then pass the resulting collection object to the get_single_attribute_value command.

- **-name *attribute_name***

A required switch and string pair that specify the name of the attribute whose value is to be returned.

If the attribute *attribute_name* is not available for the *object_type* of *object_spec*, that is, the attribute is not registered for this *object_type* and cannot be inherited, then the tool issues an error.

- **-is_specified**

An optional Boolean switch that returns 1 when the attribute was explicitly set on the object otherwise a 0 is returned

Examples

Example 1

The following example:

```
get_single_attribute_value u1/DEF -name parent_instance
```

Is equivalent to the following `get_attribute_value_list` operation:

```
index [get_attribute_value_list u1/DEF -name parent_instance] 0
```

Example 2

The following example returns the value of *parent_instance* value for pins:

```
get_single_attribute_value u1/u5/u8/ABC -name parent_instance  
u1/u5
```

Example 3

The following example returns pin names and their direction:

```
foreach_in_collection pjn [get_pins u1/*] {  
  puts "The pin [get_single_name $pin] has the direction [get_single_attribute_value \  
    $pin -name direction]."  
}
```

```
The pin u1/a has the direction input.  
The pin u1/b has the direction input.  
The pin u1/z has the direction output.
```

Example 4

When you use the `get_single_attribute` command to query an inout pin with the `has_functional_source` attribute, only the outer side of the instance is regarded:

```
get_single_attribute_value -name has_functional_source <pin>
```

Example 5

You can also use the `get_single_attribute` command to query the inner side of ports of modules (module side):

```
get_single_attribute_value -name has_functional_source [get_ports -of_pins <pin>]
```

get_single_name

Context: unspecified, all contexts

Mode: all modes

Returns a string with the name of the element specified by the *object_spec* or the *name* arguments with simplified escaped identifiers, if possible.

Usage

```
get_single_name {object_spec | -from_object_name name [-language {verilog | vhdl}]}  
[-remove_escaping] [-silent]
```

Description

This command returns the value of the name attribute for the object specified by *object_spec* or the name of the *name* with simplified escape identifiers, if possible.

Using this command with the “-from_object_names *name*” option verifies the existence of the name in the design and removes simple escaped identifiers if they are not reserved words in the design language. You can use this to identify name strings with reserved design language words.

The -language argument defines which design language escaping should be removed while processing the -from_object_names name list.

The -remove_escaping argument removes the backslash (\) and the trailing spaces in an escaped identifier. Many legacy commands such as add_clocks require the instance name to have the escape character stripped from its name. The argument also removes the escaping on reserved design language words. However, these legacy commands do accept collections as inputs in cases where the name format is not important. See the examples for an illustration of this behavior.

If *object_spec* or *name* entries are not valid, an error message displays unless the -silent switch is specified.

Arguments

- *object_spec*
A required string that specifies an object name or a single-element collection.
- **-from_object_name** *name* [-language {*verilog* | *vhdl*}]
A required switch and string pair with an optional switch and literal pair.
-language {*verilog* | *vhdl*}
An optional switch and literal pair that specifies which language (Verilog or VHDL) should be considered during the removal of simple escaping. The default is Verilog when this option is not specified.

- **-remove_escaping**
An optional switch that specifies to strip out the backslash (\) and the trailing spaces in escaped identifiers. This option is useful to interact with legacy commands and the collection is not directly passed as input to them. See [Example 3](#) for an illustration of this usage.
- **-silent**
An optional switch that specifies to suppress error messages if the object in *object_spec* does not exist.

Examples

Example 1

The following example prints out all of the modules in the database:

```
foreach_in_collection elem [get_modules] {
  puts "Module: [get_single_name $elem]"
}

Module: modb
Module: modc
Module: modd
Module: top
Module: GND
...
```

Example 2

The following example generates an error because the collection of pins returned by the `get_pins` commands contains more than one element.

```
get_single_name [get_pins u1/i*]
// Error: Collection contains more than one element.
```

Example 3

The following example uses the `-remove_escaping` argument to strip out the slash “\” from an escaped identifier.

```
get_single_name {\x[0]} -remove_escaping
x[0]
```

Example 4

The following example retrieves the a name of an instance with the `-from_object_name` option.

```
puts "from_object_name [get_single_name_list -from_object_name {deep_input1/input \^
output .le }]"
from_object_name {deep_input1/input \^output .e}
```

Hierarchy separators are retained, so the “.” is not exchanged to “/”. The “input” and “output” name parts are Verilog keywords, and the escaping is kept by this command, by default. To remove this escaping, also include the `-remove_escaping` switch.

Note

 The braces used in the example to specify a name pattern containing escape identifiers are needed to prevent the Tcl shell from interpreting the `\` character as its own escape sequence. See “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3638 for a complete description of pattern syntax and suggestions to use when the pattern is targeted for names containing escape characters.

Example 5

The following example retrieves the name of a port with the `-from_object_name` option.

```
puts "from_object_name [get_single_name -from_object_name {{ d/\a \b \c .\in }}]"
from_object_name d/a/b/c.in
```

The name is defined in braces due to the name escaping, as described in previous examples. Hierarchy separators are retained, so the “.” is not exchanged to “/”. The name does not contain language-specific keywords, so all escaping is removed.

Example 6

The following example retrieves the name of a hierarchical pin with the `-from_object_name` option.

```
set port_name {d }
if {$port_name ne [get_single_name -from_object_name $port_name]} {
  puts "No design language reserved name in [get_single_name -from_object_name
  {$port_name}]"
}
```

Due to the name escaping, the name is defined in braces. The name does not contain language-specific keywords, so the escaping is removed. Use this to check whether the port name contains reserved names in the design language.

get_ssn_option

Context: dft, patterns

Mode: setup, analysis

Returns the status of SSN in the current physical block or design specified with the `set_ssn_options` command.

Usage

```
get_ssn_option [-is_active]
```

Description

Returns the status of SSN in the current physical block or design set with the `set_ssn_options` command.

Arguments

- `-is_active`

A switch that returns 1 if there are any active SSH instances in the current mode, and 0 otherwise. This switch is valid only in analysis mode.

Examples

This example demonstrates the use of the `get_ssn_option` and `set_ssn_options` commands:

```
ANALYSIS> get_ssn_option -is_active  
1  
ANALYSIS> set_ssn_options off  
// Error: SSN mode can only be changed in SETUP mode.  
ANALYSIS> set_system_mode setup  
SETUP> set_ssn_options off  
SETUP> get_ssn_option  
off
```

get_static_dft_signal_icall

Context: dft patterns

Mode: setup, analysis, insertion

Returns the iCall corresponding to the setting specified with the `set_static_dft_signal_values` command.

Usage

```
get_static_dft_signal_icall
```

Description

Returns the iCall corresponding to the setting specified with the `set_static_dft_signal_values` command.

When in `dft -scan`, `dft -test_points`, `dft -edt` and in `patterns -scan`, this command is automatically called when going from setup to analysis mode and the resulting value is inserted as if you had used it as the first “`set_test_setup_icall [get_static_dft_signal_icall]`” call. The command exists as a stand alone command for when you want to create a stand-alone pattern set in patterns context as shown in the example below.

This command is also called during `process_patterns_specification` to obtain the iCall corresponding to the `DftControlSettings` specified in the `Patterns` wrapper.

Arguments

None

Examples

The following example shows the use of the `set_static_dft_signal_values` followed by `report_static_dft_signal_settings` and the `get_static_dft_signal_icall` inside an `open_pattern_set`. See the description of the `set_static_dft_signal_values` command to understand where the “Set value” of the DFT signals showing a “Set source” value of “Inferred” came from.

As described above, this command is automatically invoked to configure `test_setup` when in a context that supports the `set_test_setup_icall` command.

```
set_context patterns -ijtag
read_icl ../sub_block_I3.icl
set_current_design sub_block_I3
```

```
set_system_mode analysis
open_pattern_set P1
report_static_dft_signal_settings
```

```

get_synchronous_clock_groups

Context: dft, patterns

Mode: setup, analysis

Returns a Tcl list of collection handles. Each collection is a synchronous group of clock objects.

Usage

```
get_synchronous_clock_groups [-scope {capture | shift}]
```

Description

This command returns a Tcl list of collection handles. Each collection is a synchronous group of clock objects.

If no sync groups are defined, this command returns an empty list.

Arguments

- -scope {capture | shift}

An optional argument and literal pair that specifies whether to return capture or shift clock groups. By default, capture clock groups are returned.

Examples

This example creates two synchronous capture clock groups and uses this command in Tcl code to return the clock groups.

```
SETUP> add_synchronous_clock_group {clk1 clk2}
SETUP> add_synchronous_clock_group {clk3 clk4}

foreach grp [get_synchronous_clock_groups] {
  puts [lsort [get_name_list $grp]]
}

clk1 clk2
clk3 clk4
```

Related Topics

[add_synchronous_clock_group](#)

get_system_mode

Context: unspecified, all contexts

Mode: all modes

Returns the system mode.

Usage

```
get_system_mode [-previous | -is_in_transition]
```

Description

Returns the system mode.

Possible returned values are: setup, analysis, and insertion.

Arguments

- **-previous**
An optional switch that specifies to return the previous system mode.
- **-is_in_transition**
An optional switch that returns “1” when called within a callback that is running inside the system mode transition.

Examples

The following example returns the current system mode and the previous system mode. This enables you to know that you came to the insertion mode through the analysis mode.

```
get_system_mode
```

```
insertion
```

```
get_system_mode -previous
```

```
analysis
```

The following example shows how to use the **-is_in_transition** switch inside a callback to skip the operation when the feature is called within a system mode transition.

```
if {[get_system_mode -is_in_transition]}{  
    return  
}
```

Related Topics

[set_system_mode](#)

get_tcl_shell_option

Context: all contexts

Mode: setup

Introspects the Tcl shell options as specified with the `set_tcl_shell_options` command.

Usage

```
get_tcl_shell_option {-abort_dofile_on_error | -legacy_dofile_comments |  
-legacy_commands_with_spaces | -minimum_command_typing |  
-change_no_result_warnings_to_errors}
```

Description

Introspects the Tcl shell options as specified with the [set_tcl_shell_options](#) command. You can only specify one option at a time. The tool generates an error if you specify more than one option in a single command execution.

Arguments

- `-abort_dofile_on_error`
An optional switch that returns the current setting of the `abort_dofile_on_error` option. Possible return values are `off`, `on`, and `exit`.
- `-legacy_dofile_comments`
An optional switch that returns the current setting of the `legacy_dofile_comments` option. Possible return values are `off` and `on`.
- `-legacy_commands_with_spaces`
An optional switch that returns the current setting of the `legacy_commands_with_spaces` option. Possible return values are `off` and `on`.
- `-minimum_command_typing`
An optional switch that returns the current setting of the `minimum_command_typing` option. Possible return values are `off` and `on`.
- `-change_no_result_warnings_to_errors`
An optional switch that returns the current setting of the `change_no_result_warnings_to_errors` option. Possible return values are `off` and `on`.

get_test_end_icall_list

Context: dft, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Modes: setup, analysis

Returns the iCalls added to the test_end procedure by the set_test_end_icall command. Each iCall is a list containing the iProc and its arguments.

Usage

```
get_test_end_icall_list
```

Description

For each iCall added to the test_end procedure by the set_test_end_icall command, the get_test_end_icall_list command returns a list consisting of the three components that normally follow an iCall: the name of the iProc, preceded by the optional ICL instance path and separated by a dot, and one or more optional arguments to the iProc.

Arguments

None

Examples

The following example returns the iCalls added to the test_end procedure by the set_test_end_icall commands. Each iCall is a list consisting of the ICL instance path, the name of the iProc, and the arguments to the iProc.

```
set_test_end_icall "m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on \  
  edt_bypass off"  
  
set_test_end_icall "m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on \  
  edt_bypass off" -append  
  
get_test_end_icall  
  
{m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on edt_bypass off}  
{m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on edt_bypass off}
```

Related Topics

get_test_point_analysis_options

Context: dft -test_points

Mode: setup, analysis

Returns the current setting of an option specified with the `set_test_point_analysis_options` command. If you have not specified the option, the tool returns the default value of that option.

Usage

For VersaPoint test points when test point type is set to `lbist_test_coverage`:

```
get_test_point_analysis_options
  {-total_number |
   -control_points_number |
   -observe_points_number |
   -test_coverage_target |
   -pattern_count_target |
   -max_control_points_per_path |
   -exclude_cross_domain_paths |
   -observe_primary_outputs |
   -observe_blocked_faults |
   -exclude_clock_domains |
   -allow_in_xbounding_regions |
   -assume_clock_controllability |
   -shared_control_points_per_flop |
   -shared_observe_points_per_flop |
   -minimum_shift_length}
```

For VersaPoint test points when test point type is set to `edt_pattern_count`:

```
get_test_point_analysis_options
  {-total_number |
   -control_points_number |
   -observe_points_number |
   -max_control_points_per_path |
   -exclude_cross_domain_paths |
   -exclude_clock_domains |
   -observe_blocked_faults |
   -allow_in_xbounding_regions |
   -assume_clock_controllability |
   -shared_control_points_per_flop |
   -shared_observe_points_per_flop}
```

For VersaPoint test points when test point type is set to `{edt_pattern_count lbist_test_coverage}`:

```
get_test_point_analysis_options
  {-total_number |
   -control_points_number |
```

```
-observe_points_number |
-test_coverage_target |
-pattern_count_target |
-max_control_points_per_path |
-exclude_cross_domain_paths |
-observe_primary_outputs |
-observe_blocked_faults |
-exclude_clock_domains |
-allow_in_xbounding_regions |
-assume_clock_controllability |
-shared_control_points_per_flop |
-shared_observe_points_per_flop |
-minimum_shift_length}
```

Description

Returns the current setting of an option specified with the `set_test_point_analysis_options` command. If you have not specified the option, the tool returns the default value of that option.

Arguments

- **-total_number**
 An optional switch that returns the maximum number of test points to be inserted in the design. The value can be an integer or a percentage of the total number of flops. In analysis mode, it always returns an integer value. However, in setup mode it returns percentage of total number of flops if you specified the total number as the percentage of the total number of flops.
- **-control_points_number**
 An optional switch that returns the maximum number of control points to be inserted in the design. The value can be an integer or a percentage of the total number of flops.
- **-observe_points_number**
 An optional switch that returns the maximum number of observe points to be inserted in the design. The value can be an integer or a percentage of the total number of flops.
- **-test_coverage_target**
 An optional switch that returns the target fault coverage to be achieved by the number of random patterns.
- **-pattern_count_target**
 An optional switch that returns the number of random patterns to be applied to the design.
- **-max_control_points_per_path**
 An optional switch that returns the maximum number of control points to be inserted on a single path.

- **-exclude_cross_domain_paths**
An optional switch that returns the current setting of the `-exclude_cross_domain_paths` option. Possible return values are ON or OFF.
- **-observe_primary_outputs**
An optional switch that returns the current setting of the `-observe_primary_outputs` option. Possible return values are ON or OFF.
- **-observe_blocked_faults**
An optional switch that returns the current setting of the `-observe_blocked_faults` option. Possible return values are ON or OFF.
- **-exclude_clock_domains**
An optional switch that returns the list of clock domains excluded from test point insertion.
- **-allow_in_xbounding_regions**
An optional switch that returns the current setting of the `-allow_in_xbounding_regions` option. Possible return values are ON or OFF.
- **-assume_clock_controllability**
An optional switch that returns the current setting of the `-assume_clock_controllability` option. Possible return values are ideal or default.
- **-shared_control_points_per_flop**
An optional switch that returns the maximum number of control points that can be driven by a single flop.
- **-shared_observe_points_per_flop**
An optional switch that returns the maximum number of observe points that can be driven by a single flop.
- **-minimum_shift_length**
An optional switch that returns the minimum observation scan shift length for fault simulation.

Examples

Example 1

The following example returns the value of the `-total_number` option.

```
ANALYSIS> get_test_point_analysis_options -total_number  
1000
```

Example 2

The following example returns the value of the `-allow_in_xbounding_regions` option.

```
ANALYSIS> get_test_point_analysis_options -allow_in_xbounding_regions
```

OFF

get_test_point_insertion_options

Context: dft -test_points

Mode: setup, analysis

Returns the current setting of an option specified with the `set_test_point_insertion_options` command. If you have not specified the option, the tool returns the default value of that option.

Usage

```
get_test_point_insertion_options  
  {-control_point_enable | -observe_point_enable | -test_point_clock  
  -prefer_scan_cells | -capture_per_cycle_en}
```

Description

Returns the current setting of an option specified with the `set_test_point_insertion_options` command. If you have not specified the option, the tool returns the default value of that option.

Arguments

- `-control_point_enable`
An optional switch that returns the name of the enable signal for control points.
- `-observe_point_enable`
An optional switch that returns the name of the enable signal for observe points.
- `-test_point_clock`
An optional switch that returns the type of the clock to use to drive scan cells for test points. Possible return values are `system_clocks`, `always_tclk` or `tclk_as_needed`.
- `-prefer_scan_cells`
An optional switch that returns the current setting of `-prefer_scan_cells` option. Possible return values are ON or OFF.
- `-capture_per_cycle_en`
An optional switch that returns the name of the observation scan enable pin.

Examples

Example 1

The following example returns the value of the `-test_point_clock` option.

```
ANALYSIS> get_test_point_insertion_option -test_point_clock  
always_tclk
```

Example 2

The following example returns the name of control point enable signal.

```
ANALYSIS> get_test_point_insertion_option -control_point_enable
```

cp_enable

get_test_point_type

Context: dft -test_points

Mode: setup, analysis

Reports the current test point type as specified by the `set_test_point_types` command.

Usage

```
get_test_point_type
```

Description

Reports the current test point type as specified by the [set_test_point_types](#) command.

The default test point type is `edt_pattern_count`.

Arguments

None.

Examples

The following example reports the default test point type, updates the test point type to `lbist_test_coverage`, and then reports the updated test point type for your design:

```
set_context dft -test_points -no_rtl  
read_verilog design_name  
read_cell_library cell_library_name  
read_sdc sdc_filename  
get_test_point_type  
  
edt_pattern_count  
  
set_test_point_type lbist_test_coverage  
get_test_point_type  
  
lbist_test_coverage
```

Related Topics

[add_control_points](#)

[add_observe_points](#)

[set_test_point_types](#)

get_test_points

Context: dft -test_points

Mode: all modes

Returns a collection of all test points, or a collection of test points matching an optional Tcl list of specified test point attributes.

Usage

```
get_test_points [name_patterns]  
  [-type { control | observe }] [ -origin { design_analysis | user_specified } ]  
  [ -control_point_type { AND | OR } ] [ -below_instances below_instances ]  
  [ -of_pins of_pins ] [ -filter filter_expression ]  
  [ -regexp ] [ -nocase ] [ -silent ]
```

Description

This command returns a collection of all test points, or a collection of test points matching an optional Tcl list of test point name/location strings, with the option of filtering test points according to the following attributes:

- name/location (including regular expressions)
- type (control or observation)
- origin (user specified or tool generated by design analysis)
- control_point_type (AND/OR) (relevant only for control points)
- attribute values
- instance
- associated pins

Note

 Removing the “tp#” prefix from a test point name does not always produce the location of the test point. To convert a list of test point names to a list of locations, you must get the values of the location attribute for each test point. For example, you can use the following command:

```
get_attribute_value_list [get_test_points ...] -name location
```

Arguments

- name_patterns

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of test points according to their location (or name). The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no location_patterns are specified, the tool searches all test points. See section “[Glob and Regular Expression Pattern Matching](#)”

[Syntax](#)” for a complete description of the pattern syntax when the `-regex` option is used or not used.

- `-type { control | observe }`

An optional switch and literal pair that specifies to filter results based on the specified type of the test point. When omitted, all test points are considered. The option types have the following meaning:

- `control` — Test points that are for the purpose of increasing controllability in design areas where, previously, the tool could not easily force certain state values. The returned collection includes only these test points.
- `observe` — Test points that are for the purpose of increasing observability in design areas where, previously, the tool could not easily observe a certain state. The returned collection includes only these test points.

- `-origin { design_analysis | user_specified }`

An optional switch and literal pair that specifies to filter results based on the specified origin of the test point. When omitted, all test points are considered. The origin options have the following meaning:

- `design_analysis` — Test points that were generated by the tool. The returned collection includes only these test points.
- `user_specified` — Test points that were manually specified. The returned collection includes only these test points.

- `-control_point_type { AND | OR }`

An optional switch and literal pair that enable filtering results based on the type of gate used in the control type test point. Setting this flag filters out all test points that are not of the specified gate type (including all observe points).

- `-below_instances below_instances`

An optional switch and string pair that returns the test points that are below the specified instance.

- `-of_pins of_pins`

An optional switch and string pair that returns the test points that are on the specified pins.

- `-filter filter_expression`

An optional switch and string pair that returns only the test points that satisfy the provided attribute equation. See “[Test Point Data Model](#)” for the list of Test point attributes that are valid attribute names.

- `-regex`

An optional switch that specifies to the tool to interpret the value of the `name_patterns` argument as a regular expression instead of as a simple wildcard pattern. See section “[Glob](#)”

and [Regular Expression Pattern Matching Syntax](#)” for a complete description of the regular expression syntax.

- -nocase

An optional switch that specifies to the tool to perform case-insensitive pattern matching when looking for nets matching the name_patterns.

- -silent

An optional switch that suppresses the error message normally generated when the command returns an empty collection. The error message is intended to indicate a possible mistake when specifying patterns. This -silent option has no effect on any other error reporting.

Note

 You can use the -silent switch to manage the case in which an empty collection is returned. Before using the -silent switch for this purpose, refer to the [“set_tcl_shell_options -”](#) switch description for detailed usage.

Examples

Example 1

The following example returns all test points in the design:

get_test_points

```
{tp#test_module2/neg1/Z tp#test_module2/neg2/Z
tp#1/test_module2/neg1/Z tp#1/test_module2/neg2/Z
tp#test_module1/neg1/Z tp#test_module1/neg2/Z
tp#1/test_module1/neg1/Z tp#1/test_module1/neg2/Z
tp#u1/U15/Z tp#u1/U14/Z tp#u1/U75/Z tp#U64/Z
tp#u1/U71/Z tp#U114/Z tp#u1/U45/Z tp#u1/U61/Z
tp#U111/Z tp#u1/U80/Z tp#u1/U42/Z tp#u1/U70/Z
tp#U119/Z tp#u1/U22/Z tp#U128/Z tp#u1/U43/Z
tp#u1/U39/Z tp#U75/Z tp#u1/U23/Z tp#U93/Z
tp#test_module2/nand2/Z tp#u1/U25/Z tp#U109/Z
tp#u1/U17/Z tp#U98/Z tp#U81/Z tp#U92/Z tp#U104/Z
tp#u1/my_module/nand2/Z tp#u1/U31/Z tp#u1/U32/Z
tp#U73/Z tp#U130/Z tp#U131/Z tp#u1/U67/Z
tp#u1/U49/Z tp#U126/Z tp#U65/Z tp#u1/U47/Z
tp#U100/Z tp#u1/U81/Z tp#u1/U53/Z ...}
```

Example 2

The following example returns all control points below the specified instances:

get_test_points -below_instances test_module* -type control

```
{tp#test_module2/neg1/Z
tp#test_module2/neg2/Z
tp#test_module1/neg1/Z
tp#test_module1/neg2/Z
tp#test_module1/neg2/A}
```

Example 3

The following example generates a report of the test points returned by the `get_test_points` command:

```
report_test_points [get_test_points -below_instances test_module* -type control]
```

```
=====
name                type      control_point_type  enable_connection_name  clock_domain
flop_location
-----
tp#test_module2/neg1/Z control AND           /lbist_en              clk2
/test_module2/ts_default_PD_u12_cp_6sffp1_i

tp#test_module2/neg2/Z control OR           /lbist_en              clk2
/test_module2/ts_default_PD_u12_cp_8sffp1_i

tp#test_module1/neg1/Z control AND         /lbist_en              clk2
/test_module1/ts_default_PD_u11_cp_0sffp1_i

tp#test_module1/neg2/Z control OR           /lbist_en              clk2
/test_module1/ts_default_PD_u11_cp_4sffp1_i

tp#test_module1/neg2/A control OR           /lbist_en              clk1
/test_module1/ts_default_PD_u11_cp_2sffp1_i
```

get_test_setup_icall_list

Context: dft, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Modes: setup, analysis

Returns the iCalls added to the test_setup procedure by the set_test_setup_icall command. Each iCall is a list containing the iProc and its arguments.

Usage

```
get_test_setup_icall_list
```

Description

For each iCall added to the test_setup procedure by the [set_test_setup_icall](#) command, the `get_test_setup_icall_list` command returns a list consisting of the three components that normally follow an iCall: the name of the iProc, preceded by the optional ICL instance path and separated by a dot, and one or more optional arguments to the iProc.

Arguments

None

Examples

The following example returns the iCalls added to the test_setup procedure by the `set_test_setup_icall` commands. Each iCall is a list consisting of the ICL instance path, the name of the iProc, and the arguments to the iProc.

```
set_test_setup_icall "m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on \  
edt_bypass off"  
  
set_test_setup_icall "m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on \  
edt_bypass off" -append  
  
get_test_setup_icall  
  
{m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on edt_bypass off}  
{m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on edt_bypass off}
```

get_testbench_simulation_options

context: all contexts

mode: all modes

Returns the value of a given option that may have been configured using the `set_testbench_simulation_options` command.

Usage

```
get_testbench_simulation_options
  {[-default_simulator | -simulation_output_directory
   | -parallel_simulations ]
  | [-keep_simulation_data ]
  | [ -store_simulation_waveforms ]
  | [ -simulation_timeout ]
  | [ {questa | vcs} [ -simulator_options | -simulation_run_commands ]
   | -waveform_configuration_commands ] ] }
  [ -get_dictionary ]
```

Description

Returns the value of a given option that may have been configured using the [set_testbench_simulation_options](#) command.

Arguments

- `-default_simulator`
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.
- `-simulation_output_directory`
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. This default value is also used by the [check_testbench_simulations](#) `-simulation_output_directory_list` option. The default value is configurable using the [set_testbench_simulation_options](#) command.
- `-parallel_simulations`
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.
- `-keep_simulation_data`
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.

- **-store_simulation_waveforms**
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.
- **-simulation_timeout**
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.
- **questa | vcs**
A literal that specifies the simulator you want to use for simulation. The default value is “questa” from Siemens EDA.
- **-simulator_options**
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.
- **-simulation_run_commands**
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.
- **-waveform_configuration_commands**
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.
- **-get_dictionary**
A switch that specifies to return the value of the [run_testbench_simulations](#) command option having the same name. The default value is configurable using the [set_testbench_simulation_options](#) command.

Examples

This example returns the default value used for the `-simulation_output_directory` option.

```
get_testbench_simulation_option -simulation_output_directory  
./simulation_outdir
```

get_timeplate_list

Context: all contexts

Mode: all modes

Returns a list of the currently defined timeplates.

Usage

```
get_timeplate_list
```

Description

Returns a list of the currently defined timeplates. The data becomes available when you transition from setup mode to analysis mode. In analysis mode, you can change the data with subsequent [read_procfile](#) commands.

In addition to being available in analysis mode, the `get_timeplate_list` command is available in setup mode for cases when the transition to analysis mode fails after reading the procedure file, due to a DRC violation. Even though you are still in setup mode, the procedure file information is still in memory so that report and introspection commands can still be used on the information that was read.

Arguments

None

Return Values

A list of the currently defined timeplates.

Examples

```
get_timeplate_list
```

```
tp1 tp2 tp3
```

get_tool_info

Context: unspecified, all contexts

Mode: all modes

Returns information about the current tool and the current run as a Tcl result.

Usage

```
get_tool_info -name | -version | -cpu_time [ms | s | m | h | d] | -memory [b | kb | mb | gb] |  
-hostname | -interactive
```

Description

Returns information about the current tool and the current run as a Tcl result.

You must specify exactly one switch.

Arguments

- **-name**
A switch that specifies to return the name of the current tool.
- **-version**
A switch that specifies to return the version of the current tool.
- **-cpu_time [ms | s | m | h | d]**
A switch that specifies to return the user time of the process. By default, this command returns the time in seconds, but you can optionally specify one of the other units. The possible units are:
 - ms — Specifies the time unit is milliseconds.
 - s — Specifies the time unit is seconds.
 - m — Specifies the time unit is minutes.
 - h — Specifies the time unit is hours.
 - d — Specifies the time unit is days.
- **-memory [b | kb | mb | gb]**
A switch that specifies to return the memory usage. By default, this command returns the usage in bytes, but you can optionally specify one of the other units.
 - b — Specifies the memory usage unit is bytes.
 - kb — Specifies the memory usage unit is kilobytes.
 - mb — Specifies the memory usage unit is megabytes.
 - gb — Specifies the memory usage unit is gigabytes.
- **-hostname**
A switch that specifies to return the hostname.

get_tool_info

- -interactive

A switch that specifies to return a “1” when the tool is in interactive mode or a “0” when running from a dofile in batch mode.

Examples

Example 1

The following examples return information about the current tool:

```
get_tool_info -name
```

```
tessent_shell
```

```
get_tool_info -version
```

```
2020.3
```

```
get_tool_info -cpu_time
```

```
2.773
```

```
get_tool_info -memory
```

```
228343808.0
```

```
get_tool_info -hostname
```

```
my_host
```

Example 2

The following shows how to format the returned double value for the -memory switch:

```
puts [format "Used memory %.2f GB." [get_tool_info -memory GB]]  
//which prints the following:
```

```
...
```

```
Used memory 1.26 GB.
```

The -cpu_time switch also returns double values.

[set_tcl_shell_options](#)

[set_tool_options](#)

get_tool_option

Context: all contexts

Mode: all modes

Returns certain Tessent Shell options from the `set_tool_options` command.

Usage

```
get_tool_option -reapply_settings_after_reelaboration | -allow_vhdl_2008
```

Description

Returns certain Tessent Shell options from the [set_tool_options](#) command.

Arguments

- `-reapply_settings_after_reelaboration`
A switch that returns the re-elaboration settings for the loaded design.
- `-allow_vhdl_2008`
A switch that returns the whether any blocks contain VHDL 2008 constructs.

get_trace_flat_model_option

Context: all contexts

Mode: setup, analysis

Introspects the default behavior of the `trace_flat_model` command.

Usage

```
get_trace_flat_model_option [-controllability] [-latch] [-tag_condition] [-stop_condition]
    [-stop_at_first_tag] [-max_levels] [-map_tag_to_design_module_boundary]
```

Description

Introspects the default behavior of the `trace_flat_model` command.

You can only specify one option at a time. The tool generates an error if more than one option is specified in a single command execution.

Arguments

- `-controllability`

An optional switch that returns the current setting of the controllability option. Possible return values are:

`controlling`— Gates are only traversed if the other inputs have simulated constant values making a single input directly controlling the output without an inversion.

`constant` — Only pins with a constant value are traversed. This mode is useful to find the source of a constant value.

`unblocked` — Gates are only traversed if the other inputs do not have simulated constant values making the input blocked from the output pin. Only unblocked combinational paths are traversed.

`connected`—With this value, gates are always traversed when reached.

- `-latch`

An optional switch that returns the current setting of the latch option. Possible return values are:

`normal` — A latch is traced through only if the simulated value in the current simulation context makes the latch satisfy the specified controllability requirements. In case of “`-controllability connected`” all latch input pins - including the latch enable pin - are traced through.

`transparent` — All latches are traced through the data input, set and reset pins regardless of the value at the latch enable pin. The latch enable pin is not traced through.

- `-tag_condition`

An optional switch that returns the current setting of the tag condition option. The returned value is an attribute expression. For more details about filtering attribute equation formats, refer to “[Attribute Filtering Equation Syntax](#)” on page 3636.

- **-stop_condition**
An optional switch that returns the stop condition for the trace. The returned value is an attribute expression.
- **-stop_at_first_tag**
An optional switch that returns the current setting of the `-stop_at_first_tag` option. This option specifies whether to interrupt tracing when the first tag object with the specified controllability is found. Possible return values are: {ON | OFF}
- **max_levels**
An optional switch that returns the current setting of the `max_levels` option. This option specifies the maximum level of gates to trace. Possible return values are: unlimited or a number.
- **-map_tag_to_design_module_boundary**
An optional switch that returns the current setting of the `map_tag_to_design_module_boundary` option, which specifies whether to map the tag points to gate_pins outside of library cells. Possible return values are: {ON | OFF}

Examples

Example 1

The following example returns the current setting for the `-controllability` option.

```
get_trace_flat_model_option -controllability
```

Example 2

The following example returns the current setting for the `-tag_condition` option.

```
get_trace_flat_model_option -tag_condition
```

Example 3

The following example returns the current setting for `-stop_condition` option.

```
get_trace_flat_model_option -stop_condition
```

Example 4

The following example returns the current setting for the `-stop_at_first_tag` option.

```
get_trace_flat_model_option -stop_at_first_tag
```

Example 5

The following example returns the current setting for the `-max_levels` option.

```
get_trace_flat_model_option -max_levels
```

Example 6

The following example returns the current setting for the `-latch` option.

```
get_trace_flat_model_option -latch
```

get_transcript_style

Context: unspecified, all contexts

Mode: all modes

Returns the keyword that specifies the style in which the tool transcripts commands.

Usage

```
get_transcript_style [-result_collection_limit | -argument_collection_limit |  
-one_collection_entry_per_line]
```

Description

Returns the keyword that specifies the style in which the tool transcripts commands.

The `get_transcript_style` command returns one of four keywords previously set with the `set_transcript_style` command. Possible return values are: `off`, `full`, `tool_commands_only`, and `input_only`.

Note that issuing the `set_transcript_style` command without an argument prints the style. Issuing `get_transcript_style` returns a value that you can assign to a variable for later use (see example below).

Arguments

- `-result_collection_limit`
An optional switch that specifies that the command is to return the number of collection entries shown in the interactive mode.
- `-argument_collection_limit`
An optional switch that specifies that the command is to return the number of collection entries shown in the listing when a collection is passed to a command as an argument.
- `-one_collection_entry_per_line`
An optional switch that specifies that the command is to return the collections of arguments and results with one entry per line.

Examples

The following example stores the current transcript style in a variable, turns off transcribing, then later restores the original transcript style:

```
set old_transcript_style [get_transcript_style]  
set_transcript_style off
```

```
... # do something with transcribing turned off  
set_transcript_style $old_transcript_style
```

get_tsdb_info

Context: dft, patterns

Mode: setup, analysis, insertion

An introspection command used to extract information stored in the *.tsdb_info* files found in the *dft_inserted_design* directories of the TSDB directories.

Usage

```
get_tsdb_info [module_name] [-design_identifier id] [-silent]
    {-dictionary [-specified_module_only] | -exists | -level | -tsdb_info_file
    | -most_recent_design_identifier | -library_name | -ids_with_dates | -opened_tsdb_list
    | -child_blocks_dict | -version | -gate_extension }
```

Description

An introspection command used to extract information stored in the *.tsdb_info* files found in the [dft_inserted_designs](#) directories of the TSDB directory. Except for the `-dictionary` switch, all other switches apply to a specific *module_name* and *design_id* set. If the design is not elaborated in the session, you need to specify the *module_name* and potentially the *design_id* for which you want the requested information.

Arguments

- *module_name*
A string value that specifies the name of a module, or a collection containing a single module that identifies the module for which the *tsdb_info* is requested. If unspecified, then the tool uses the *module_name* returned by the [get_current_design](#) command.
- `-design_identifier id`
A switch and string pair that specifies the *design_id* associated with the design for which the *tsdb_info* is requested. You only need to specify this switch if the TSDB contains [dft_inserted_designs](#) directories associated with more than one *design_id*. The tool issues an error if there is more than one *design_id* available and this switch is not specified.
- `-silent`
A switch that suppresses the error message generated when a *module_name* and *design_id* combination is specified, and there is no [dft_inserted_designs](#) directory found for the combination in any of the opened TSDB directories. In this case, the tool returns a null value.
- `-dictionary`
A switch that returns the complete information set found in all *tsdb_info* files in the opened TSDBs. When this switch is specified, the tool ignores the specified *module_name* and

design_id values, and returns the information for all design and *design_id* pairs that exist. The format of the dictionary is as follows:

```
module_name {
  design_identifier {
    tsdb_info_file           <leaf name of .tsdb_info file>
    tsdb_info_version        integer
    creation_date            integer //epoch time
    level                    chip | physical_block | sub_block
    icl_extraction_needed    On | Off
    full_path                <relative path of .tsdb_info
file from current directory>
    library_name             <logical library name
of module_name>
    gate_extension           <extension of concatenated netlist>
    opened_tsdb_list         <list of opened tsdb(s)when created>
    child_blocks_dict {
      module_name design_identifier
      ...
    }
  }
}
```

- -specified_module_only

An optional switch used in conjunction with the -dictionary switch that returns only the dictionary for the specified *design_name/design_id*.

- -exists

A switch that returns a value that indicates whether a *design_name/design_id* set exists. Return values are as follows:

- 1 —Indicates the *design_name/design_id* set exists.
- 0 —Indicates the *design_name/design_id* set does not exist.

- -level

A switch that returns the design level associated with the specified *design_name/design_id* set. The returned value reflects the [set_design_level](#) command's value used when the tool created the *dft_inserted_design* directory.

- -tsdb_info_file

A switch that returns the full path name of the *.tsdb_info* file associated with the specified *design_name/design_id* set.

- -most_recent_design_identifier

A switch that returns the most recent *design_id* for the specified *design_name*.

- -library_name

A switch that returns the logical library name the specified *design_name* is associated to.

- **-ids_with_dates**
A switch that returns the list of *design_ids* associated with the specified *design_name*. The returned value is a list of list containing the following three elements: the *design_id* string; the date represented as an integer (epoch time); and the date represented in your local time zone.
- **-opened_tsdb_list**
A switch that returns the list of TSDB directories that were open when the tool created the *.tsdb_info* file. The paths are reported relative to the current working directory in Tessent Shell, unlike those in the file itself, which are relative to the directory in which the tsdb info file resides. The first path in the list is always the relative path to the tsdb in which the tsdb info file resides.
- **-child_blocks_dict**
A switch that returns a dictionary listing the child blocks found immediately below the specified *design_name/design_id* set. The keys are the child block names, and the values are the *design_ids*.
- **-version**
A switch that returns the version of the *.tsdb_info* file. Return values are as follows:
 - 1 — Indicates the current version.
 - 0 — Indicates that there is no child block dictionary. If you specify the **-child_block_dict** switch, then the tool returns an empty dictionary.
- **-gate_extension**
A switch that returns the extension used by the concatenated netlist for the specified *design_name/design_id* set.

Examples

The following example illustrates the use of several switches of the `get_tsdb_info` command. Note how the `format_dictionary` command is used to format the returned dictionary when the `-dictionary` switch is used.

help get_tsdb_info

```
get_tsdb_info [ <module_spec> ] [ -design_identifier <id> ] [ -silent ]  
{ -dictionary | -exists | -level | -tsdb_info_file |  
  -most_recent_design_identifier | -library_name | -ids_with_dates |  
  -opened_tsdb_list | -child_blocks_dict | -version | -gate_extension }
```

```
puts [format_dictionary [get_tsdb_info -dictionary]]
```

get_tsdb_info

```

get_tsdb_list

Context: all contexts

Mode: all modes

Returns a Tcl list of directory paths, relative to the current working directory, corresponding to all opened TSDB directories.

Usage

```
get_tsdb_list
```

Description

Returns a Tcl list of directory paths, relative to the current working directory, corresponding to all opened TSDB directories.

When the default or specified TSDB output directory is already created, it is returned in the list even if there was no explicit `open_tsdb` command for it.

Arguments

None

Examples

The following example shows the use of the `get_tsdb_list` command before and after some are closed.

```
get_tsdb_list
```

```
/home/projects/chipa/tsdbs/corea.tsdb /home/projects/chipa/tsdbs/coreb.t  
sdb /home/projects/chipa/tsdbs/corec.tsdb
```

```
close_tsdb [list ${tsdb_home}/corea.tsdb ${tsdb_home}/coreb.tsdb ]
```

```
get_tsdb_list
```

```
/home/projects/chipa/tsdbs/corec.tsdb
```

Related Topics

[close_tsdb](#)

[set_tsdb_output_directory](#)

get_tsdb_output_directory

Context: unspecified, dft, patterns

Mode: setup, analysis, insertion

Returns the directory used by the `process_dft_specification` command—the directory previously set by the `set_tsdb_output_directory` command.

Usage

```
get_tsdb_output_directory
```

Description

The `get_tsdb_output_directory` command returns the value that the `process_dft_specification` command uses. The TSDB output directory defaults to `./tsdb_outdir` until you run the `set_tsdb_output_directory` command. When you run either the `get_tsdb_output_directory` or `set_tsdb_output_directory` command, the tool verifies that the specified path is a writable directory if it already exists, or that the parent directory is a writable directory if it does not.

The `process_dft_specification` command is currently the only command that makes use of the TSDB directory.

Arguments

None

Examples

Example 1

The following example stores the TSDB output directory into a Tcl variable called `tsdb_outdir`.

```
set tsdb_outdir [get_tsdb_output_directory]
```

Example 2

The following example shows a possible error that can be generated when invoking the command.

```
set_tsdb_output_directory dir1  
exec "rm -r dir1; touch dir1"  
get_tsdb_output_directory  
  
// Error: The specified tsdb_output_directory 'dir1' exists but is not a  
// directory.  
// Error: Directory was either deleted or its write permission changed  
// between now and the invocation of set_tsdb_output_directory command.
```

Related Topics

[set_tsdb_output_directory](#)

get_validated_objects

Context: dft, patterns

Mode: setup, analysis, insertion

Validates the values supplied to arguments or switches of a command created with the `register_tcl_command` command.

Usage

```
get_validated_objects object_spec [-allowed_object_type_list allowed_object_type_list]  
    | [-argument_name argument_name | -switch_name switch_name]
```

Description

This command accepts a list of object names or a collection of objects, and that verifies if their types are present in the permitted object type list. When this condition is met, the tool returns a collection with all object names converted to objects.

If you are validating the value of a switch, specify this value using the `-switch_name` switch. For example, if you are validating the value provided to a switch called `-below_instance`, specify `"-switch_name below_instance"`. The error messages start with `"Supplied -below_instance value contains..."`

If you are validating a positional argument, use the `-argument_name` switch to specify the argument's name. For example, if you are validating the `<port_spec>` argument, then specify `-argument_name port_spec`. The error messages start with `"Supplied <port_spec> contains..."`. If you do not specify either the `-argument_name` switch or the `-switch_name` switches, the error messages start with `"Supplied <node_spec> contains..."`.

Arguments

- *object_spec*
A Tcl list with one or more object names or a collection containing one or more objects.
- `-allowed_object_type_list` *allowed_object_type_list*
A switch-value pair that specifies which object types are permitted. The value is a Tcl list of one or more object names. The permitted object names are as follows:
 - port
 - pseudo_port
 - pin
 - net
 - module
 - instance

- gate_pin
- icl_port
- icl_pin
- icl_module
- icl_instance

When unspecified, the default permitted object type list is {port pin net pseudo_port gate_pin}.

- -argument_name *argument_name*

A switch value pair that specifies the name of the argument to be validated. Specifying this option affects the error messages that are generated when the `object_spec` contains invalid objects. When both the `-argument_name` and the `-switch_name` switches are not specified, the error messages start with “Supplied `<node_spec>` contains...” When the `-argument_name` switch specifies a value `xxx`, then the error messages start with “Supplied `<xxx>` contains...”

For example, if you are validating the `<port_spec>` argument, then specify `-argument_name port_spec`, and the error messages start with “Supplied `<port_spec>` contains...”

- -switch_name *switch_name*

A switch value pair that specifies the name of a switch value to be validated. Specifying this option affects the error messages that are generated when the `object_spec` contains invalid objects. When both the `-argument_name` and the `-switch_name` switches are not specified, then the error messages start with “Supplied `<xxx>` contains...” When the `-switch_name` switch specifies a value `xxx`, then the error messages start with “Supplied `-xxx` value contains...”

For example, if you are validating the value provided to a switch called `-below_instance`, specify `-switch_name below_instance`, and the error messages start with “Supplied `-below_instance` value contains...”

Examples

The following example uses the `get_validated_objects` command with the body of a registered Tcl command to validate the argument of a command having this syntax:

```
get_instance_leaf_name instance_spec
```

The proc implementing this command uses the `get_validated_objects` as follow:

```
proc get_instance_leaf_name.body {args} {  
  array set ARGS {instance_spec ""}  
  array set ARGS $args  
  
  set instance_objects [get_validated_objects $ARGS(instance_spec) \  
    -argument_name instance_spec \  
    -allowed_object_type_list instance]  
  
  #If I make it hear, instance_objects contains a collections of instances  
}
```

get_write_patterns_options

Context: patterns -ijtag, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: analysis, setup

Returns introspection results from either port lists or vector callbacks.

Usage

Usage for Port Lists

```
get_write_patterns_options -existing_used_ports | -additional_port_list | -all_used_port_list  
| -port_direction port_direction | -port_offstate port_offstate
```

Usage for Vector Callbacks

```
get_write_patterns_options -vector_callback_list [-trigger {before_first | after_last |  
every_cycle}] | -received_callback_port_list proc_name  
| -returned_callback_port_list proc_name
```

Description

Returns introspection results from either port lists or vector callbacks.

Arguments

- **-existing_used_ports**

A required switch that returns the current subset of existing design ports as a Tcl list of port names or gate_ids. The list is in the order that the ports are listed in the final pattern file, minus the additional ports. If there is no subset of existing_used_ports active, the full list of default design ports is returned.

- **-additional_port_list**

A required switch that returns a Tcl list of lists of the additional port names, and port directions. This is the order in which the additional ports are listed in the final pattern file that is written. If there is no additional ports specified, an empty list is returned. The format of the list of lists is as follows:

```
{ { port_name direction} { port_name direction} ...}
```

- **-all_used_port_list**

A required switch that returns the current subset of existing design ports and any specified additional ports as a Tcl list of lists of the port names and port directions. If no subset of existing design ports is active, then the default list of design ports plus any additional ports are returned. The format of the Tcl list is the same as that used for -additional_port_list.

- **-port_direction** *port_direction*

A required switch and string pair that returns the port direction for a named port, where the port direction is one of input, output, or inout. This command works on all ports, including any additional ports added with -additional_port.

- **-port_offstate *port_offstate***

A required switch and value pair that returns the binary offstate state value of ‘0’ or ‘1’ for a named port if the port is a clock port. If the port is not a clock port, then the state value of ‘N’ is returned.

- **-vector_callback_list [-trigger {before_first | after_last | every_cycle}]**

A required switch and literal pair that returns the current vector callback proc names as a Tcl list. If there are no callbacks, an empty list is returned. If the –trigger option is used, only the name of the callback for that trigger is returned.

- **-received_callback_port_list *proc_name***

A required switch and value pair that returns the callback ports as a Tcl list of names in the same order in which the port_values are present in the vector_set. This introspection command can be used within vector_callback procs to have the list of ports and the order that are present in all port_values strings within vectors. The *proc_name* value must be the name of a Tcl proc that was already registered as a callback procedure using the “[set_write_patterns_options -vector_callback](#)” command.

- **-returned_callback_port_list *proc_name***

A required switch and value pair that returns the callback ports as a Tcl list of names in the same order in which the port_values are present in the vector_set. This introspection command can be used within vector_callback procs to have the list of ports and the order that are present in all port_values strings within vectors. The *proc_name* value must be the name of a Tcl proc that was already registered as a callback procedure using the “[set_write_patterns_options -vector_callback](#)” command.

Examples

Example 1

This example show the results of this command if called after the port_list has been set.

```
ANALYSIS> puts [join [get_name_list [get_write_pattern_options -all_used_port_list]] “\n”]
```

```
ijtag_si input  
ijtag_so output  
ijtag_tms input  
ijtag_tck input  
myNewInput input  
myNewOutput [1] output  
myNewOutput [0] output
```

get_xclock_handling

Context: all contexts

Mode: all modes

Returns the options specified with the `set_xclock_handling` command.

Usage

```
get_xclock_handling [-pessimistic_simulation]
```

Description

Returns the options specified with the [set_xclock_handling](#) command, which specifies whether the sequential element model outputs X when any of its clock inputs become X.

Arguments

- `-pessimistic_simulation`

An optional switch that returns the setting (“1” (on) or “0” (off)) that affects the output of the edge-triggered sequential element model when the clock port becomes X as shown in [Table 6-25](#) on page 2798.

Related Topics

[set_xclock_handling](#)

get_xy_instance

Context: patterns -scan_diagnosis, patterns -silicon_insight

Mode: setup, analysis

Returns a Tcl list of cell instances located at the specified location in the LDB.

Usage

```
get_xy_instance x y [-ldb_units]
```

Description

This command returns a Tcl list of instance names that overlap the specified x and y coordinates, as stored in the LDB. You must provide chip-level coordinates, which the tool automatically converts to core-level coordinates if a chip-mapped core-level LDB is currently open. When using a chip-mapped core-level LDB, you must set the layout core instance before invoking this command.

By default, the command assumes the specified coordinates are expressed in microns units. You can override the default by specifying the `-ldb_units` switch.

Arguments

- `x y`
Required x and y chip-level coordinates within the LDB. The default is microns.
- `-ldb_units`
An optional switch that enables you to specify the coordinates in LDB units rather than the default micron units.

help

Context: unspecified, all contexts

Mode: all modes

Lists commands and associated usage syntax.

Usage

help [*command_name*] [-manual] [-all]

Description

Lists commands and associated usage syntax.

Specifying the help command without any arguments returns a list of all available commands. Specifying a single command name displays its usage syntax.

Arguments

- *command_name*

An optional string that specifies the name of the command for which you want help. Entering the first part of a command name returns a list of commands that start with the specified string. The *command_name* can include wildcard characters. For example, you can use an “*” to match zero or more characters at the position of the asterisk in the string.

You also can use the tab completion method on available commands, which supplies missing characters between underscores. For example, specifying “help se_sy_m” and pressing the Tab key inserts “help set_system_mode” on the command line. Tab completion also works in this same way when invoking any tool command.

If a single command is returned, its usage syntax also displays.

- -manual

An optional switch that displays the reference manual description for the specified command. If you use this switch without specifying a command name, the tool opens the Tessent documentation system, giving you access to all the manuals for the product group.

- -all

An optional switch that displays all command matches, including unavailable commands, which are identified with the “(...unavailable...)” notation. Specifying “help *unavailable_command_name*” displays the reason why a particular command is unavailable.

Examples

Example 1

The following example returns the usage syntax for the history command:

```
help history
```

```
history [ <count> ] [ -Nonumbers ] [ -Reverse ] [ -Save <savefile> ]
```

Example 2

The following example returns all commands in the current mode that begin with the string “set_design”:

help set_design

```
set_design_include_directories
set_design_macros
set_design_sources
```

Example 3

The following example returns all commands in the current mode that contain the string “design”:

help *design*

```
delete_design
get_current_design
set_current_design
set_design_include_directories
set_design_macros
set_design_sources
write_design
```

Example 4

The following example returns all commands containing the string “design”, including those that are unavailable:

help *design* -all

```
delete_design
find_design_names      (...unavailable...)
get_current_design
set_current_design
set_design_include_directories
set_design_macros
set_design_sources
write_design
```

history

Context: unspecified, all contexts

Mode: all modes

Displays a list of previously run commands.

Usage

history [*list_count*] [-Nonumbers] [-Reverse] [-Save *filename*]

Description

The history command lists commands that you have previously run.

You can use command line editing to recall a previous command and edit it for submission as a new command.

A leading number precedes each command line in the history list that indicates the order in which the commands were entered.

Arguments

- *list_count*
An optional integer that specifies for the tool to display only the specified number (*list_count*) of most recent run commands. If no *list_count* is specified, the tool displays all previously run commands.
- -Nonumbers
An optional string that specifies for the tool to display the history list without the leading numbers. This is useful for creating dofiles. The default displays the leading numbers.
- -Reverse
An optional switch that specifies for the tool to display the history list starting with the most recent command rather than the oldest.
- -Save *filename*
An optional switch and string pair that specifies the name of a file to which to write the command history. This is useful for creating dofiles.

Examples

Example 1

The following command saves the command history into a dofile for later execution.

```
history -save dofile1.txt
```

Example 2

The following command displays the history list with leading numbers, starting with the oldest command.

history

```
1 help hist
2 dof instructor/fault.do
3 set_system_mode analysis
4 set_fault_type stuck
5 add_faults -all
6 create_patterns
7 report_statistics
8 report_faults -class ATPG_UNTESTABLE
9 analyze_fault /I$20/en -stuck_at 1
10 set_system_mode setup
11 set_system_mode analysis
12 set_fault_type iddq
13 add_faults -all
14 create_patterns
15 report_statistics
16 history
```

iApply

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Triggers the retargeting of all queued iRead and iWrite commands.

Usage

iApply [-end_in_pause]

Description

Triggers the retargeting of all queued iRead and iWrite commands.

This command causes the retargeting engine to calculate the optimal sequence of scan loads, primary input stimulations, and primary output observations to satisfy all queued iRead targets and iWrite targets, as illustrated in [Figure 4-7](#).

The number of ParallelIO time frames and Scan time frames used to satisfy all queued up iWrite and iRead commands depends on the number of queued commands and the circuit topology described in the ICL description.

The solution criteria for the iWrite commands is that all specified iWrite values are achieved and present at the end of the iApply time frame. The order in which they become satisfied is unknown and is chosen by the solver in order to minimize the number of clock cycles needed to complete the tasks. The solver is designed to minimize transition on the writable objects and limits them to a single transition per iApply time frame if the ICL circuit permits it.

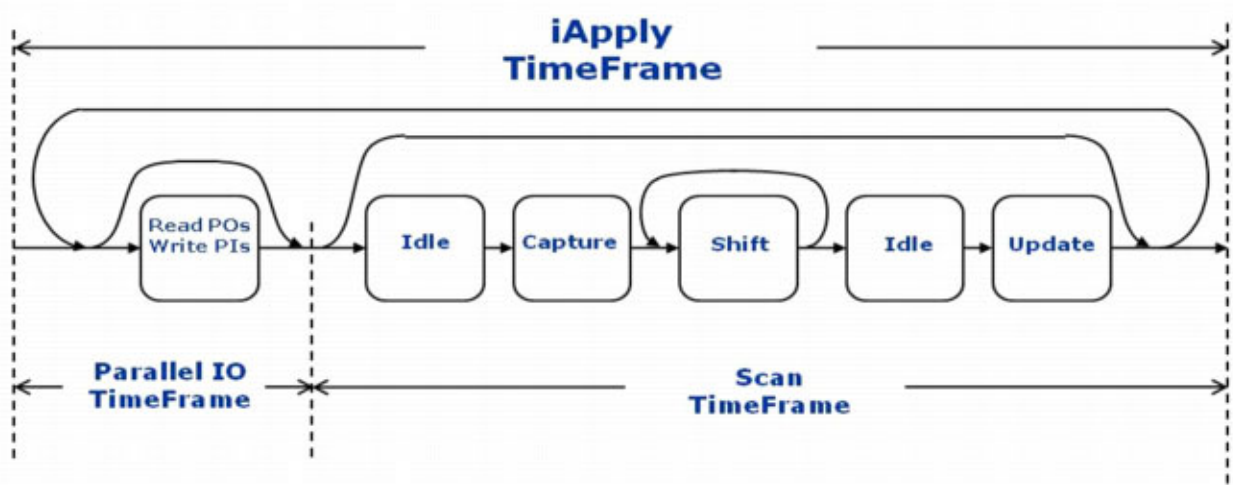

If it is not possible to achieve all specified iWrite values at the end of the time frame, the specified iWrite command set is said to have no solution. The iRead object only needs to be observed once anywhere within the time frame. The value is strobed at the first opportunity that it becomes observable and is then ignored if re-observed on subsequent Scan or parallel I/O time frames.

If there is no solution for the retargeting task, the iRead targets and iWrite targets are taken out of the queue and the current state of the circuit is retained. An error message appears in this case. If there is a solution, the solution is appended to the opened pattern set. The circuit state is updated to reflect the situation after the actions within the current iApply time frame have been applied.

You can use the optional -end_in_pause switch to help create IJTAG scan chain integrity tests. This switch enables you to observe the same values at the scan output that have been shifted in

before. When you do not use this switch, the shift register content is always overwritten by the capture values before being observed at the scan output.

Figure 4-7. iApply Time Frame

Arguments

- `-end_in_pause`

An optional switch that helps you to create IJTAG scan chain integrity tests. The `-end_in_pause` switch changes the handling of the last scan load of the iApply and the first scan load of the next iApply.

Note that the following explanation refers to states of a finite state machine (FSM) of an IEEE 1149.1 (JTAG) TAP controller. “IR” is instruction register, and “DR” is data register. For a complete explanation about how the TAP controller operates, refer to the IEEE 1149.1 standard document.

When you use the `-end_in_pause` switch, and the last scan load is a “TAP scan load” (capture, shift and update activity is controlled by a TAP state machine), then the TAP state machine ends in the pause-DR or pause-IR state (that is, the tool performs no update-DR/update-IR). The first scan load of the next iApply starts from there and performs another scan load (obviously without capture-DR/capture-IR) before returning to RTI (run test/idle).

When you use the `-end_in_pause` switch, and the last scan load is an ordinary scan load (capture, shift, and update activity is controlled by the appropriate CaptureEnPort, ShiftEnPort, UpdateEnPort), then the “update” of the last scan load of the iApply is skipped. The first scan load of the next iApply skips the “capture.” For more information about the CaptureEnPort, ShiftEnPort, UpdateEnPort keywords, refer to “ICL and PDL Modeling” in the *Tessent IJTAG User's Manual*.

You can use this switch only when the iWrite targets are all part of ScanRegisters. Those ScanRegisters must be configurable to appear as one concatenated scan chain.

Return Values

None

Examples

Example 1

In the following example, two iWrite and two iRead commands are queued up when the iApply command is issued. The solver starts from the current state of the ICL circuit and looks for a series of ParallelIO and Scan time frames to have u1.ina equal to “11” and u1.inb equal to “0” at the end of the iApply time frame, and to have observed at least once the u1.out1 and u1.out2 objects.

The number of ParallelIO and Scan time frames needed to achieve the objective depends on the ICL network. If both u1.ina and u1.inb shared a common source in ICL, then the given PDL could not be satisfied because it would be impossible to have u1.in1 high with u1.inb low together at the end of the iApply time frame.

```
iWrite u1.ina 0b11  
iWrite u1.inb 0b0  
iRead u1.out1  
iRead u1.out2 0x7  
iApply
```

Example 2

The following example applies a chain integrity test.

```
open_pattern_set chain_pattern  
  iWrite myRegister 0b00110011  
  iApply -end_in_pause  
  iRead myRegister 0b00110011  
  iApply  
close_pattern_set
```

iCall

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Calls an iProc registered against the ICL module associated with the specified *effective_icl_instance_path*.

Usage

```
iCall [icl_instance_path.]iprocc_name [arguments...]
```

Description

Calls an iProc registered against the ICL module associated with the specified *effective_icl_instance_path*.

The *effective_icl_instance_path* is computed by concatenating the following three components:

- iProc instance path — Path that exists when running commands specified within an iProc; it is set to the *effective_icl_instance_path* used in the iCall command that called the iProc. This value is empty when the iCall is not specified within an iProc.
- iPrefix path — Path specified as the argument to the iPrefix command since the beginning of the *open_pattern_set* for commands that are not inside an iProc, or since the beginning of the iProc for commands that are inside an iProc. If no iPrefix command has yet been specified in the current scope, this value is empty.
- *icl_instance_path* — An optional path specified in front of the *iprocc_name* inside the iCall command, or in front of the *icl_object* inside other PDL commands such as [iWrite](#), [iRead](#), and [iClock](#).

The *effective_icl_instance_path* is illustrated in the examples that follow.

The other arguments of this command are passed to the iProc in the same order as they appear in the command line. You must specify at least as many arguments as there are variables without default values in the corresponding iProc specification. For arguments defined with a default value in the associated iProc, their value takes on the default value when omitted.

Error Reporting

Similar to ordinary Tcl procs, iProcs can be nested, and this nesting can even be a mixture of iProcs and ordinary Tcl procs. An iProc can be called from within an ordinary Tcl proc that in turn has been called from within another iProc. If an error occurs in such a situation, it is often desirable to know the exact call stack to find the root-cause of the error. Tessent Shell reuses the

Tcl infrastructure to provide this sort of information. The built-in variable “errorInfo” contains useful data about the call stack and the location where the erroneous command can be found.

In case of an error, the Tcl interpreter of Tessent Shell fills the variable appropriately, but it treats iProcs and ordinary Tcl procs in the same way. Therefore, the content of the “errorInfo” variable shows the internal representation of the failing iProc. This internal representation consists of one or more namespace identifiers, the name of the module for which the iProc is registered and the name of the iProc. These parts are separated by double colons.

Example

```
ANALYSIS> puts $errorInfo
can't read "iDoNotExist": no such variable
  while executing
  "puts $iDoNotExist"
    (procedure "::mentor::iprocs::module1::run_test" line 21)
    invoked from within
    "::mentor::iprocs::module1::run_test {blue} "
      invoked from within
      "iCall block2_I1.inst1.run_test blue"
```

The content of the variable “errorInfo” shows a procedure called “::mentor::iprocs::module1::run_test”. This refers to the iProc “run_test”, which is registered for the module “module1” in the iProc namespace “::mentor::iprocs”. The lines above also show the command by which this iProc has been called (“iCall block2_I1.inst1.run_test blue”) and the root cause of the error (can't read "iDoNotExist": no such variable).

Arguments

- [icl_instance_path.]**iProc_name**
Name of an iProc preceded by an optional icl_instance_path and separated by a dot. The specified iProc must have been registered against the ICL module associated with the *effective_icl_instance_path*.
- arguments...
Additional optional arguments that are passed to the iProc procedure. The number of required arguments depends on the definition of the iProc and on the existence of default values for the iProc arguments.

Return Values

None. Unlike normal Tcl proc, even if the iProc contains the Tcl return command, the specified value is not returned by the iCall command, which is consistent with the IEEE 1687 standard.

Examples

The following example assumes an ICL module called myInstrument1 exists and this module is instantiated four times below the current design with the following instance paths:

```
core1_i1.myInst1_i1core1_i1.myInst1_i2core1_i2.myInst1_i1core1_i2.myInst1_i2
```

The ICL module `myInstrument1` has an ICL sub-module called `myInstrument1_decode_logic` that is instantiated within `myInstrument1` as “`decode_logic`”.

This numbered example illustrates the declarations of `iProcs` against the `myInstrument1` and `myInstrument_decode_logic` modules, and the use of the `iCall` command to run them against various instances of `myInstrument1`.

Line 1 issues the first `iProcsForModule` command for `myInstrument1`, which means `iProcs` declared afterward are registered against that module. For that reason, the `iProcs` declared at line 2 and 12 are registered against `myInstrument1`.

Line 24 issues the second `iProcsForModule` command, which means the next `iProcs` are registered against the module `myInstrument1_decode_logic`.

The commands starting at line 41 are not inside an `iProc` so the `iProc instance path` value is empty when computing the `effective_icl_instance_path` for those commands.

The `iCall` on line 42 has an `effective_icl_instance_path` of `core1_i1.myInst1_i1` because `iPrefix path` is currently set to `core1_i1` (from the `iPrefix` command on line 41) and `icl_instance_path` is specified as `myInst1_i1`.

The `iCall` on line 42 specifies the value for the `cnt` argument while the second argument is left to the default value specified within the `iProc` declaration.

The `iCall` on line 43 overwrites the value of the second argument. Note that the first argument is required because it has no default values defined in the `iProc` declaration.

The `iCall` on line 5 is inside of an `iProc`, so it has an `iProc instance path` value that is equal to the `effective_icl_instance_path` value of the `iCall` that called the `iProc`. Looking at the `iCall` command on line 5 when called by the `iCall` on line 41, its `effective_icl_instance_path` is `core1_i1.myInst1_i1.decode_logic` because `iProc instance path` is `core1_i1.myInst1_i1`, `iPrefix path` is `decode_logic`, and `icl_instance_path` is empty.

The ICL instance `core1_i1.myInst1_i1.decode_logic` is an instance of ICL module `myInstrument1_decode_logic` and the `proc Setup` is registered against this module on line 25 because it follows the `iProcsForModule` command specified on line 24.

```

1  iProcsForModule myInstrument1
2  iProc run_testa {cnt {mode red}} {
3      iCall CheckStart
4      iPrefix decode_logic
5      iCall Setup $cnt $mode
6      iCall run $mode
7      iPrefix
8      iCall decode_logic.Status
10     iRead decode_logic.cnt $cnt
11 }
12 iProc CheckStart {} {
13     iRead go Fail
14     iRead done No
15     iApply
16 }
17 iProc run {mode} {
18     set cycles(red) 50
19     set cycles(blue) 90
20     set cycles(green) 70
21
22     iRunLoop $cycles($mode) -tck
23 }
24 iProcsForModule myInstrument1_decode_logic
25 iProc Setup { cnt mode } {
26     iWrite mode $mode
27     if {$mode == "red"} {
28         iWrite p1 0b0
29         iWrite p1(2) 0b1
30     }
31     iApply
32     iWrite enable Yes
33     iApply
34 }
35 iProc Status {} {
36     iRead done Yes
37     iRead go Pass
38     iRead count $cnt
39     iApply
40 }
41
41 iPrefix core1_i1
42 iCall myInst1_i1.run_testa 5
43 iCall myInst1_i2.run_testa 10 blue
44 iPrefix
45 iCall core1_i2.myInst1_i1.run_testa 15 red

```

iClock

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Checks whether a controlling clock path from a valid clock source to the specified clock port exists.

Usage

iClock [*icl_instance_path*].*icl_clock_port*

Description

Checks whether a controlling clock path from a valid clock source to the specified clock port exists.

This command takes into account the [iClockOverride](#) specifications and the FreqMultiplier and FreqDivider properties in the ICL description.

Prior to issuing this command, clock path sensitization must have been performed using the appropriate iWrite and iApply commands such that SelectedBy sources of ICL ClockMultiplexers seen along the traced path have known constant values.

If clock tracing fails before reaching a primary input, an error is generated. If the primary input is reached but does not have an associated [add_clocks](#) command to specify the clock is active with a known period, an error is also generated.

The cumulative effective frequency multiplier is computed along the traced clock path and the final number is stored against the specified clock port. This value is later used to normalize the iRunLoop command to a common tester period as described in the [iRunLoop](#) command description.

Arguments

- [*icl_instance_path*].*icl_clock_port*

Name of an internal or top-level clock port defined inside the ICL description. The specified clock port must be a port declared as a ClockPort or ToClockPort inside the ICL and it must be found at the computed effective_*icl_instance_path*. The [iCall](#) command description describes how the effective_*icl_instance_path* value is computed and the factors that affect it.

Return Values

None

Examples

In the following example, an `iClock` command is first specified to check that the reference source pin of the PLL has a controlling source to a primary input of the current design, and that the port has a specified clock period as defined by an [add_clocks](#) command.

The `iWrite` and `iApply` commands then program the PLL to a multiplication factor of 1.5 and set the clock multiplexer to the state you require.

The result of the PLL setup is reflected by the `iClockOverride` command such that the `iClock` definition on `inst1.mbist_i1.clk`, which traces to the PLL, properly computes the correct multiplication factor.

The first `iRunLoop` command specifies for the PLL to lock in less than 200 reference clock cycles. The second `iRunLoop` results in a loop of 4000 ($6000 \times \frac{2}{3}$) clock cycles at the current design boundary. For more information on the `iRunLoop` scaling algorithm, see the `iRunLoop` command description.

```
iClock inst1.pll.ref  
iWrite inst1.pll_setup.mult 0b0100  
iWrite inst1.pll_setup.source 0b01  
iApply  
iClockOverride inst1.pll.vco -freqMultiplier 3 -freqDivider 2  
iRunLoop 200 -sck inst1.pll.ref  
iClock inst1.mbist_i1.clk  
iRunLoop 6000 -sck inst1.mbist_i1.clk
```

iClockOverride

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Models how the functional clocking has been programmed.

Usage

```
iClockOverride [icl_instance_path.]icl_clock_port -source [icl_instance_path.]icl_clock_port  
[-freqMultiplier multiplier] [-freqDivider divider]
```

```
iClockOverride [icl_instance_path.]icl_clock_port -period period [s | ms | us | ns | ps | fs | as]
```

Description

Models how the functional clocking has been programmed.

System clocking syntax inside ICL is adequate to describe a constant frequency multiplication and division number. With ClockMultiplexers in ICL, it is possible to model alternative sources as long as the select lines of the multiplexers are controlled by ijtag registers. The functional clocking path of ijtag instruments is not required to be controlled by ijtag itself. As long as the current functional clocking is properly modeled, the [iRunLoop](#) commands can be normalized correctly.

You should have a way to set up the functional clock using the ijtag network if you need to change it between patterns. You can use the complete syntax available inside the test_setup procedure to program an arbitrary functional clock system. You simply use this iClockOverride command to model how the functional clocking was programmed. Even if the multiplication factor is controlled by ijtag registers, you use the iClockOverride command to describe the effect of the newly written value. This is illustrated in the [iClock](#) command example.

You can use the iClockOverride command to override only the source, or only the cumulative multiplication/divider value, or both. If the -source option is not specified, the source is unchanged; it remains the source documented in ICL, or the last iClockOverride -source value that may have been specified within the current open pattern set.

If the -freqDivider and the -freqMultiplier arguments are both specified, both are overridden. Specifying just -freqDivider without -freqMultiplier or vice versa, sets the unspecified option to 1. If neither of the -freqDivider and the -freqMultiplier arguments are specified, the previous -freqDivider and the -freqMultiplier values are preserved, regardless of whether they came from ICL or a previously specified iClockOverride.

Arguments

- **[icl_instance_path.]icl_clock_port**
A required value that specifies an internal clock port defined inside the ICL description. The specified clock port must be a port declared as a ToClockPort inside the ICL and it must be found at the computed effective_icl_instance_path. The [iCall](#) command description describes how the effective_icl_instance_path value is computed and the factors that affect it.
- **-source [icl_instance_path.]icl_clock_source_port**
An optional switch and value pair that specifies an internal or top-level clock port defined inside the ICL description. The specified clock port must be a port declared as a ClockPort or ToClockPort inside the ICL and it must be found at the computed effective_icl_instance_path. The [iCall](#) command description describes how the effective_icl_instance_path value is computed and the factors that affect it.
- **-freqMultiplier *multiplier***
An optional switch and value pair that overrides the frequency multiplication factor between the *[icl_instance_path.]icl_clock_port* and its source. It's value defaults to 1 when -freqDivider is specified otherwise it defaults to the previously defined value, either from the definition in ICL or from a previous iClockOverride command on the given *[icl_instance_path.]icl_clock_port*
- **-freqDivider *divider***
An optional switch and value pair that overrides the frequency ratio between the *[icl_instance_path.]icl_clock_port* and its source. It's value defaults to 1 when -freqMultiplier is specified otherwise it defaults to the previously defined value, either from the definition in ICL or from a previous iClockOverride command on the given *[icl_instance_path.]icl_clock_port*
- **-period *period***
An optional switch and value pair with optional time unit that overrides the period of the ToClockPort. The default time unit is "ns". A ToClockPort with a specified period serves as an internal clock source, that is, as an oscillator.

Return Values

None

Examples

The following example assumes both inst1.inst2.sysclock and clk2 are declared as ToClockPorts in the ICL description. The first iClockOverride command only overrides the source and leaves the multiplication and division number unchanged. The second iClockOverride command overrides the frequency multiplication factor to 10 and the frequency division ratio to 1.

```
iClockOverride inst1.inst2.sysclock -source clk2  
iClockOverride inst1.inst2.sysclock -freqMultiplier 10
```

iComparePort

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iTopProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Enables you to compare a value on an arbitrary primary output port or bidirectional port inside an ijtag pattern set.

Usage

iComparePort *object_spec value* [-after *state_transition_list*]

Description

Enables you to compare a value on an arbitrary primary output port or bidirectional port inside an ijtag pattern set.

An iComparePort or an iForcePort command is only permitted in an iTopProc and not in a normal iProc as it is not retargetable upward.

It is best to keep the iProcs that only interact with the ijtag ports separated from the ones using the iComparePort command so that you maintain the ability to retarget the bulk of your PDL.

The effect of the iComparePort is applied on the next [iApply](#) command or the next [iRunLoop](#) command and lasts until it is iCompared to an X. You can use the -after switch to delay the compare and have it appear only after a specific state transition.

An iComparePort command remains active until one of the following events happen:

- The iComparePort is overwritten with another iComparePort command or — in case of bidirectional ports — with another iForcePort command.
- The pattern set is closed and the next pattern set is opened without the `-no_initial_ireset` switch. (Note: this only applies to the context “patterns -ijtag”).
- If an iComparePort command is part of an iTopProc called from within an iMerge block, then the lifetime of the iComparePort command is limited to the retargeting of that iTopProc.

This is done for the following reason: If there are conflicting iComparePort specifications in concurrent iCalls, the associated iTopProcs must be retargeted in series. If the iComparePort specifications survived the end of the iTopProc, the active iComparePort after the iMerge `-end` would depend on the (undefined) order of the retargeting of the concurrent iCalls. This non-deterministic behavior must be avoided.

You can use this command in an iCall used as part of test_setup for ATPG, however, it makes the iTopProc un-retargetable upward. You should avoid doing so at least until you reach the chip level.

Arguments

- *object_spec*

A collection containing the top level output or bidirectional port/ports. If you are using this command on a port that is not described in the top ICL module (a non-IJTAG port), you must have read the interface view of the top level Verilog or VHDL module to get the list of ports available to compare. Use “read_verilog -interface_only” or “read_vhdl -interface_only” to read in the port list prior to issuing the set_current_design command as shown here:

```
set_context patterns -ijtag -no_rtl
read_verilog top.v -interface_only
read_icl top.icl
set_current_design top
```

- *value*

A string representing the value to compare ‘0’, ‘1’, ‘X’ or ‘Z’. You can use the 0b prefix to specify a multi-bit binary number or the 0x prefix to specify an hexadecimal number. The X value means to stop comparing the port.

- *-after state_transition_list*

An optional switch-value pair used to specify a Tcl list of state transitions after which the compare is active. The compare is active in the cycle after one of the listed state transitions has happened and is off otherwise. The list of available state transitions are all the ones supported by the IEEE1149.1 state machine and state names are the same names used in SVF.

RESET, IDLE,

DRSELECT, DRCAPTURE, DRSHIFT, DREXIT1, DRPAUSE, DREXIT2, DRUPDATE
IRSELECT, IRCAPTURE, IRSHIFT, IREXIT1, IRPAUSE, IREXIT2, IRUPDATE

Examples

The following example compares two bits of a bussed port during the entire scan load needed to iWrite the TDR.

```
iComparePort GPIO[3:0] 0b1XX0  
iWrite tdr[7:0] 0b0  
iApply
```

The following example performs the same comparison as the previous example except that the port is compared when the state machine goes from DRSelect to DRCapture, which corresponds to when the boundary scan cell captures the input ports.

iComparePort

```
iComparePort GPIO[3:0] 0b1XX0 -after DRSELECT:DRCAPTURE  
iWrite tdr[7:0] 0b0  
iApply
```

[iProcsForModule](#)

identify_redundant_faults

Context: dft -edt, patterns -scan

Mode: analysis

Identifies redundant faults among current faults whose redundancy has not yet been determined.

Usage

identify_redundant_faults

Description

Note

By default, the [create_patterns](#) command automatically performs redundant fault identification at the conclusion of the run.

Identifies redundant faults among current faults whose redundancy has not yet been determined.

Identifies combinationally redundant (RE) faults from among those faults in the current fault list whose redundancy has not been determined yet.

This command is useful in situations where the tool has not specifically checked some faults for redundancy, but where establishing their redundancy might improve test coverage. The following are examples of such situations:

- When the tool generates patterns using named capture procedures, it does not identify RE faults. You might improve test coverage by using this command at the end of such an ATPG session.
- When the tool simulates external patterns, it does not identify RE faults among the undetected faults. You might improve test coverage by using this command after the simulation.

This command only targets faults not yet proven to be either RE or non-RE. For example, the command does not target a fault currently classified as `det_simulation` (DS) or that was classified as DS before but is now uncontrolled (UC) or unobserved (UO). The command is meaningful only when the current fault type is stuck-at, bridge, transition, or UDFM.

Arguments

None

Examples

Example 1

The following example creates patterns using named capture procedures, then identifies the RE faults:

```
set_system_mode analysis  
set_capture_procedures on -all  
create_patterns  
  
...  
// There may be unidentified redundant faults when generating patterns  
// with named capture procedures defined, which may lead to lower test  
// coverage being reported.  
// To perform redundant fault identification, invoke the command:  
// identify_redundant_faults  
...

iForcePort

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iTopProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Enables you to force a constant value to an arbitrary primary input port or bidirectional port inside an ijtag pattern set.

Usage

```
iForcePort object_spec {value [ -not_persistent ] | -release } [-after state_transition_list]
```

Description

Enables you to force a constant value to an arbitrary primary input port or bidirectional port inside an ijtag pattern set.

An iComparePort or iForcePort command is only permitted in an iTopProc and not in a normal iProc as it is not retargetable upward.

It is best to keep the iProcs that only interact with the ijtag ports separated from the ones using the iForcePort command so that you maintain the ability to retarget the bulk of your PDL.

The effect of the iForcePort command is applied on the next [iApply](#) command or the next [iRunLoop](#) command. You can use the -after switch to delay the application of the value to the port and have it appear only after a specific state transition.

An iForcePort command without the `-not_persistent` switch remains active until one of the following events happen:

- The iForcePort is overwritten with another iForcePort command or — in case of bidirectional ports — with another iComparePort command.
- The iForcePort is explicitly terminated by means of the `-release` switch.
- The pattern set is closed and the next pattern set is opened without the `-no_initial_ireset` switch. (Note: this only applies to the context “patterns -ijtag”).
- If an iForcePort command is part of an iTopProc called from within an iMerge block, then the lifetime of the iForcePort command is limited to the retargeting of that iTopProc.

This is done for the following reason: If there are conflicting iForcePort specifications in concurrent iCalls, the associated iTopProcs must be retargeted in series. If the iForcePort specifications survived the end of the iTopProc, the active iForcePort after

the iMerge –end would depend on the (undefined) order of the retargeting of the concurrent iCalls. This non-deterministic behavior must be avoided.

You can use this command in an iCall used as part of test_setup for ATPG, however, it makes the iTopProc un-retargetable upward. You should avoid doing so until you reach the chip level.

Arguments

- *object_spec*

A collection containing the top level input or bidirectional port/ports. If you are using this command on a port that is not described in the top ICL module (a non-IJTAG port), you must have read the interface view of the top level Verilog or VHDL module to get the list of ports available to force. Use “read_verilog -interface_only” or “read_vhdl -interface_only” to read in the port list prior to issuing the set_current_design command as shown here:

```
set_context patterns -ijtag -no_rtl
read_verilog top.v -interface_only
read_icl top.icl
set_current_design top
```

If the port is associated to a pulse waveform in the timeplate, you can only force the port to the off value.

Asynchronous clocks cannot be forced to any value.

ICL ports that are part of a ScanInterface cannot be forced to any value.

ICL ports that are involved in the scan path configuration of active parts of the ICL network cannot be forced to any value.

If there is a CT0, CT1 or CTZ constraint on the port, then the iForcePort command can only be used in combination with the matching value.

- *value*

A string representing the value to force as ‘0’, ‘1’, ‘X’ or ‘Z’. You can use the 0b prefix to specify a multi-bit binary number or the 0x prefix to specify a hexadecimal number. Just like with the iWrite command, the X value has special meaning. If you use the iForcePort command on a bused port and any of the bits is specified with an X, it means to leave that bit unchanged and preserve its previous value as if the bit was not even part of the iForcePort command as shown here:

```
iForcePort GPIO[3:0] 0b0xx1
```

is equivalent to

```
iForcePort GPIO[3] 0b0
iForcePort GPIO[0] 0b1
```

- *-not_persistent*

An optional switch that specifies that the forced value can be overwritten by the IJTAG solver if needed during later retargeting operations. This option has no effect when the

iForcePort command is used on a port that is not described in ICL as the solver never interacts with those ports.

- -release

An optional switch that specifies that the specified bits are now no longer persistent and the solver is enabled to change their values if needed during future retargeting operations. Using “iForcePort P1 -release” is equivalent to issuing “iForcePort P1 <current_value> -not_persistent” but it does not require you to know the current value.

- -after *state_transition_list*

An optional switch-value pair used to specify a Tcl list of state transitions after which the value is applied to the port. The list of available state transitions are all the ones supported by the IEEE1149.1 state machine, and state names are the same names used in SVF.RESET, IDLE, DRSELECT, DRCAPTURE, DRSHIFT, DREXIT1, DRPAUSE, DREXIT2, DRUPDATE, IRSELECT, IRCAPTURE, IRSHIFT, IREXIT1, IRPAUSE, IREXIT2, IRUPDATE

Examples

Example 1

The following example forces 2 bits of a bussed port:

```
iForcePort GPIO[3:0] 0b1XX0  
iApply
```

It is equivalent to specifying

```
iForcePort GPIO[3] 0b1  
iForcePort GPIO[0] 0b0  
iApply
```

Example 2

The following example applies the value 1 to GPIO[3] when the state machine goes from Shift-DR to Exit1-DR and the value 0 to GPIO[0] when the state machine goes from Exit1-DR to Update-DR.

```
iForcePort GPIO[3] 0b1 -after DRSHIFT:DREXIT1  
iForcePort GPIO[0] 0b0 -after DREXIT1:DRUPDATE  
iApply
```

[open_pattern_set](#)

iMerge

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Specifies the beginning and the end of a set of iCall commands that are meant to be processed in parallel, as much as possible, in the final representation of the test patterns.

Usage

```
iMerge {-begin[-error_on_conflict] | -end}
```

Description

Specifies the beginning and the end of a set of iCall commands that are meant to be processed in parallel, as much as possible, in the final representation of the test patterns.

iCall is the only PDL command which is permitted in between iMerge -begin and iMerge -end.

In the iProcs called by the iCalls, Tessent IJTAG identifies any resource conflicts, such as two PDL commands writing to the same register, and all conflicts arising from reservations done by means of the command iTake. All conflicting commands are then processed serially. For the remaining iCall commands, Tessent IJTAG tries to find an optimal parallel solution.

Arguments

- **-begin**
A required switch that marks the beginning of the set of iCall commands to be processed in parallel.
- **-error_on_conflict**
An optional switch that specifies to issue an error when there is a conflict rather than process the conflicting events serially. In the case of nested iMerge blocks, you only need to specify this switch on the outermost iMerge specification; the specification applies to all iMerge processes that are called from within the block.

Refer to “[iMerge Conflict Reporting](#)” in the *Tessent IJTAG User's Manual* for more information.
- **-end**
A required switch that marks the end of the set of iCall commands to be processed in parallel.

iMerge

Return Values

None

Examples

```
iMerge -begin -error_on_conflict  
iCall proc1  
iCall proc2  
iCall proc3  
...  
iMerge -end
```

[iPrefix](#)

import_clocks

Contexts: patterns, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: setup

Imports functional clocks defined during the pre-DFT design rule checking.

Usage

```
import_clocks [-core core_name] [-verbose]
```

Description

This command imports functional clocks defined during the pre-DFT design rule checking—see “[Pre-DFT Clock Rules \(DFT_C Rules\)](#)” on page 3101.

This command is called in setup mode before you perform design rule checks. Use this command to import functional clocks if you are doing capture with these clocks, and that you already defined during pre-DFT design rule checking.

If the tool encounters a missing clock port while running this command, it reports a warning about any missing ports and imports all existing clocks.

Arguments

- `-core core_name`

An optional switch that specify the core name from which functional clocks should be imported. If the `-core` switch is not specified, the tool attempts to match a core description against the module name of the specified module(s) or instance(s). If the tool does not find a direct match for a core description and a module or instance, the tool attempts to identify a match using the tool’s default module matching options, which are consistent with what synthesis tools typically use. For information on the default module matching options and how they can be changed, see the description for the “[set_module_matching_options -suffix_pattern_list](#)” option.

If the tool is unable to match a specified module or instance, it issues an error with a reminder that the user can explicitly specify which core description to use with the `-core` switch.

- `-verbose`

An optional switch that outputs a note to stdout for each clock added by the command.

import_dfm

Context: patterns -scan_diagnosis

Mode: analysis

Imports a Calibre-compatible results database (RDB) file into a violations database (VDB).

Usage

```
import_dfm -rdb rdb_file -layer layer_name -type {cell | open | bridge | cell_open |  
cell_bridge | cell_ton | cell_toff} [-sample n] [-replace]
```

Description

Imports a Calibre-compatible results database (RDB) file into a violations database (VDB).

The import_dfm command verifies that the DFM rule violations in the VDB match the layout geometries in the LDB. It then populates the VDB with the DFM rule violations.

Note

DFM shapes that fail verification are still imported into the VDB and used during annotation.

You must have previously opened the LDB and VDB with the open_layout command. Otherwise, Tessent Diagnosis issues an error message.

For more information, see “[Diagnosis for Design for Manufacturability Analysis](#).”

Arguments

- **-rdb *rdb_file***

A required switch and string pair that specifies the Calibre-compatible DFM RDB file.

- **-layer *layer_name***

A required switch and string pair that specifies the layer at which the polygons in the RDB file should be compared to diagnosis suspect bounding boxes. The layer name must match one of the layers that appear in the diagnosis report when you have enabled at least one of layout-aware diagnosis and cell-aware diagnosis.

For cell suspects, the layer name is always CELL. For open and bridge suspects, the layer names come from the LEF/DEF files. For cell_open, cell_bridge, cell_ton, and cell_toff suspects, the layer names come from the Tessent CellModelGen UDFM file.

Note

You can override the default layer names used in the UDFM file. For more information, see the *Tessent CellModelGen Tool Reference*.

- **-type {cell | open | bridge | cell_open | cell_bridge | cell_ton | cell_toff}**
A required switch and literal that specifies the type of DFM violation that you want to report, where `cell_open`, `cell_bridge`, `cell_ton`, and `cell_toff` only apply to cell-aware defects for cell-aware diagnosis. The `cell_bridge` violation supports inter-layer bridge defects.
- **-sample *n***
An optional switch and string pair that specifies a percentage value from 0 to 100. This value specifies the number of shapes that are verified against the LDB. Setting this value to 0 prohibits verification.

This switch has no effect on diagnosis. Use it to improve verification runtimes with the caveat that lowering the value decreases the verification accuracy.
- **-replace**
An optional switch that specifies to remove from the VDB the DFM rule with the same rule name, and layer, and to replace it with the new RDB information.

Examples

The following example opens an LDB, creates the directory for Tessent Diagnosis to write the VDB into, and then imports the specified RDB files into the VDB created in the *design.ldb* directory. For OPEN violations, it verifies 10 percent of the rule violations in the VDB during verification. In addition, it imports inter-layer bridge violations for layers M0-M1.

```
open_layout design.ldb
```

```
import_dfm -rdb id_100.rdb -layer route_2 -type OPEN -sample 10 -replace  
import_dfm -rdb inter_layer_bridges_M0_M1.rdb -layer M0-M1 -type CELL_BRIDGE -replace
```

Related Topics

[annotate_diagnosis](#)

[delete_dfm](#)

[report_dfm_rules](#)

import_patterns_from_svf

Context: patterns -ijtag

Mode: analysis

Enables you to integrate the actions described in the SVF file into the currently open pattern set.

Usage

```
import_patterns_from_svf filename [-scan_interface scan_interface]  
    [-maintain_model_state on | off]
```

Description

Enables you to integrate the actions described in the SVF file into the currently open pattern set.

The `import_patterns_from_svf` command can only be used if a pattern set is currently open. The appropriate actions from the SVF file are appended to the existing retargeted actions. The internal state of the ICL network is updated accordingly. All comments in the SVF file are converted into iNote statements unless the comment starts with `!!`, in which case they are ignored.

The `import_patterns_from_svf` command can be used either if there is a complete ICL description without any blackboxes, or if the top module is a blackbox. `import_patterns_from_svf` cannot be used if one of the instances, which are accessed by the SVF patterns, is a blackbox.

An ICL blackbox module is a module that contains only ports, scan interfaces and organizational elements like parameters, attributes, enums and aliases, but none of the following:

- DataRegister or ScanRegister
- DataMux, ClockMux or ScanMux
- LogicSignal
- OneHotDataGroup or OneHotScanGroup
- Instance
- AccessLink
- The Source property of an output port
- The Enable property of an output port

If the imported SVF file contains SIR or SDR commands, and you create retargeted PDL with the `"write_patterns -pdl"` command, the output PDL contains illegal references to placeholder register names (`tessent_blackbox_data_register`, `tessent_blackbox_instruction_register`) if the

top module is a blackbox. These register names can also be found in the results of the `get_pattern_set_data` command.

The `import_patterns_from_svf` command cannot be used in an iMerge block or in an iProc. At the time when this command is used, there must not be any queued iWrite, iRead, iForcePort or iComparePort commands.

The `import_patterns_from_svf` command has the following limitations:

- The SVF import must not leave the TAP controller in RESET state.
- ENDDR IRPAUSE and ENDDR RESET are not supported. The SVF command ENDDR can be used with the arguments DRPAUSE and IDLE only.
- ENDIR DRPAUSE and ENDIR RESET are not supported. The SVF command ENDIR can be used with the arguments IRPAUSE and IDLE only.
- The SVF command RUNTEST can only be used in its simplest form:
RUNTEST *run_count* [TCK|SCK]. The *run_state*, *min_time*, *max_time* and *end_state* arguments are not supported.
- The commands RUNTEST, SDR and SIR cannot be used if the TAP controller is in RESET state.
- The STATE command does not accept several arguments, that is, it is not possible to specify the TAP state transitions the TAP controller should choose to get to the specified end state. Only the end state itself can be specified.
- TRST Z is not supported. TRST only accepts ON, OFF and ABSENT.
- Native SVF does not have a possibility to express the measurement of high impedance at an output port. Therefore `write_patterns -svf` creates a dedicated annotation for that purpose: “!TESSENT_PRAGMA expect_z”. This annotation is not understood by `import_patterns_from_svf`, it is simply ignored.

Arguments

- ***filename***
A required string that specifies the name of a SVF file to be read. The file can be gzip-compressed or uncompressed
- **`-scan_interface` *scan_interface***
An optional switch and string pair that specifies the name of the TAP scan interface in the ICL top module. If this switch is omitted, there must be a unique TAP scan interface in the ICL top module. A scan interface is identified as a TAP scan interface by the existence of a TMS port.

Note

 A pattern set can have active scan interfaces and inactive scan interfaces. If there are several TAP scan interfaces, but only one of them is active, then the `-scan_interface` switch can be omitted.

- `-maintain_model_state` on | off

An optional switch and literal pair that specifies how the SVF reader operates. When set to off, the reader operates in “blackbox mode”, in that it does not apply the SDR (Scan Data Register) and SIR (Scan Instruction Register) commands to the internal state of the IJTAG network, nor does it check if the internal state of the IJTAG network matches the length of the provided SDR/SIR data. The default value is on.

Examples

The following example converts an SVF file to a PDL file:

```
SETUP> set_context patterns -ijtag -no_rtl
SETUP> read_icl data/icl/*.icl
SETUP> set_current_design chip
SETUP> add_clocks ClkA -pulse_always -period 10ns
SETUP> set_system_mode analysis
ANALYSIS> open_pattern_set test1 -tester_period 100ns
ANALYSIS> import_patterns_from_svf jtagtest1.svf
ANALYSIS> close_pattern_set
ANALYSIS> write_patterns jtagtest1.pdl -pattern_sets test1 -pdl
ANALYSIS> exit -f
```

import_scan_mode

Context: `dft -edt`, `dft -edt -logic_bist`, `dft -test_points`, `patterns -scan`

Mode: setup

Imports configuration settings from `tcd_scan`.

Usage

```
import_scan_mode [-core core_name] [scan_mode_name] [-no_reset_design]
  [-fast_capture_mode {on | off}] [-verbose] [-silent]
```

Description

Imports the following configuration settings from `tcd_scan`:

- Adds scan chains used in the scan mode.
- Adds EDT instruments used in the scan mode.
- Adds OCC instruments used in the scan mode.
- Configures scan clocks used in the scan mode.
- Configures DFT signals used in the scan mode.
- Adds scan clock pulses to shift procedure.
- Adds scan enable signal forces to shift procedure.

Note

 To override default parameter values of imported scan instruments, use the [set_core_instance_parameters](#) command.

By default, the tool resets the design when you issue the `import_scan_mode` command unless you specify the `-no_reset_design` switch. In addition, the tool uses an auto generated [test procedure file](#).

Arguments

- `-core core_name`

An optional switch that specify the core name from which the scan mode should be imported. If the `-core` switch is not specified, the tool attempts to match a core description against the module name of the specified module(s) or instance(s). If the tool does not find a direct match for a core description and a module or instance, the tool attempts to identify a match using the tool's default module matching options, which are consistent with what synthesis tools typically use. For information on the default module matching options and how they can be changed, see the description for the "[set_module_matching_options -suffix_pattern_list](#)" option.

If the tool is unable to match a specified module or instance, it issues an error with a reminder that the user can explicitly specify which core description to use with the `-core` switch.

- *scan_mode_name*

An optional string that specifies the scan modes to import. This switch is only required when there are multiple scan modes. If only one scan mode is specified in the TSDB, it is imported by default.

- `-no_reset_design`

An optional switch that specifies that the design should not be reset. By default, the design is reset when the `import_scan_mode` command is issued.

- `-fast_capture_mode on | off`

An optional switch that specifies using fast capture mode. The default is off.

- `-verbose`

An optional switch that displays additional information about the configuration settings being imported.

- `-silent`

An optional switch that specifies to suppress warning messages.

Examples

Example 1

The following example overrides an EDT instrument parameter on all EDT instruments imported with the `import_scan_mode` command:

```
import_scan_mode edt_mode
set_core_instance_parameters -instrument_type edt \
  -parameter_values {edt_low_power_shift_en on }
```

Example 2

This example does not reset the design and imports the design in the only mode that the TSDB has:

```
import_scan_mode -no_reset_design
```

For designs with multiple scan modes, you need to specify the *scan_mode_name* to import.

Example 3

This example imports the design in *scan_mode_name* “`edt_mode`”. The tool uses an auto generated test procedure file and resets the design. The `-verbose` switch shows additional configuration settings being imported.

```
import_scan_mode edt_mode -verbose
```

Example 4

This example shows how the `import_scan_mode` command uses the `int_mode` as the *scan_mode_name*. Additionally, the example demonstrates how to use a specific test procedure file with the `set_procfile_name` command, which you specify after issuing the `import_scan_mode` command:

```
import_scan_mode int_mode -verbose  
set_procfile_name my_custom.testproc
```

index_collection

Context: unspecified, all contexts

Mode: all modes

Extracts a single object at a specified index in a collection and creates a new collection containing only that object.

Usage

`index_collection collection index`

Description

Extracts a single object at a specified index in a collection and creates a new collection containing only that object.

The base collection remains unchanged.

Arguments

- ***collection***
A required string that specifies the collection to be searched.
- ***index***
A required value that specifies the index into the collection. Permitted values are integers from 0 to “*sizeof_collection* - 1”. Also permitted is the keyword “end”, which is the equivalent of “*sizeof_collection* - 1”.

Examples

The following example shows the first and last object in a collection being extracted.

```
set c1 [get_instances {u1 u2 u3}]
```

```
{u1 u2 u3}
```

```
get_name_list [index_collection $c1 0]
```

```
u1
```

```
get_name_list [index_collection $c1 [expr [sizeof_collection $c1] -1 ]]
```

```
u3
```

```
get_name_list [index_collection $c1 end]
```

```
u3
```

```
get_name_list [index_collection $c1 end-1]
```

```
u2
```

iNote

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Inserts a note in the opened pattern set.

Usage

iNote [-status | -comment] *string*

Description

The iNote command inserts a note in the opened pattern set, attached to the time corresponding to where the iNote command is run. When the pattern set is written to a pattern file using the [write_patterns](#) command, the note appears as an annotation in the pattern file at the appropriate location. For simulation test benches, the note is displayed when the cycle containing the annotation is simulated.

Using verilog_insert Pragma Within an iNote String

The following pragma can be used as the start of the iNote string argument to insert native Verilog code inside the Verilog test bench. The Verilog code specified in the pragma is run at the time when the iNote annotation would normally be inserted. See “[Example 2.](#)”

The pragma uses the following format:

```
iNote “tessent_pragma verilog_insert native verilog statement suitable within an initial block”
```

The native Verilog statement following the pragma must be code that is permitted to go inside an initial block. This code must be terminated with a semicolon or the end keyword following the normal Verilog grammar rules. “[Example 2](#)” shows the insertion of a while loop and the triggering of an event.

Using iWrite/iRead Variables Pragma Within an iNote String

You can use the iNote command to define [iWrite](#) variables within the PDL to make it easier to change values on the tester using patching. You can also use it to define [iRead](#) variables within the PDL to make it easier to map TDO miscompares into meaningful information.

The “[PDL Retargeting With Symbolic Variables](#)” section of the *Tessent IJTAG User's Manual* describes the special iNote string used to define the symbolic variable and how the information is forwarded into an output patterns file such as STIL.

Arguments

- **-status**
An optional switch that is used to denote important milestones in the test flow.
- **-comment**
An optional switch that is used to provide detailed comments on any PDL that may be used to generate test vectors.

Note

 There is no real difference between the **-status** and **-comment** switches. They help clarify the intention of the iNote, but the behavior of the pattern is exactly the same.

The iNote command never translates the **-status** and **-comment** switches into Annotations of the STIL file. If you want these switches translated, include them in the message string, such as iNote “-status message” or iNote -status “-status message” and likewise for **-comment**.

- ***string***
The comment string or note to be added to the pattern set at the proper time. This must be a single normal Tcl string. Multiple words must be enclosed in quotation marks or braces.

Return Values

None

Examples

Example 1

In the following example, the first iNote command is attached to the beginning of the pattern. The iNote string contains a variable that is substituted before being sent to the iNote command. The second iNote command is attached to the time corresponding to the time reached to run the previous iApply actions. The last iNote appears after the loop.

```
iNote -status "Setting up controller instance $inst"  
iWrite mode blue; iApply  
iNote -comment "Running controller"  
iWrite enable On; iApply  
iRunLoop 30 -tck  
iNote -comment "Checking results"  
iRead results pass; iApply
```

Example 2

The following example makes use of the special `insert_verilog` `tessent_pragma` (shown in green in the example code block) to perform two tasks. As previously described, the text that follows the “`tessent_pragma insert_verilog`” prefix in the iNote string is native Verilog code that is

suitable for being inserted inside an initial Verilog block. The example uses one special iNote to insert the following line at a specific time in the test bench:

```
while (dut.cm.pll.lock !== 1'b1) #100;
```

This code while construct makes the test bench wait for the lock output pin on the PLL instance to become 1 before continuing with the rest of the operation. As described in the comments in the dofile example, this is used to mimic the effect of a STIL MatchLoop that would be used on the tester.

The second special iNote in the example is to trigger a Verilog event in the test bench:

```
-> check_clock${::clock_id_cnt}_period;
```

The event that is triggered by this command lets the Verilog code that checks the period of the clock to do its jobs. See the “always @(check_clock`id)_period)” statement in the check_clock_string defined in the dofile. This string is processed by the “string map” Tcl command to replace the ‘(id), ‘(path) and ‘(period) values before being sent to a file. That file is later included into the test bench using the [SIM_MODULE_INCLUDE](#) parameter in the [write_design](#) command. Notice that the [SIM_INSTANCE_NAME](#) parameter is also used in the write_design command so that the instance name of the chip within the test bench is constant and can be use in the Verilog code inserted into the test bench. The “dut” string in the instance path shown above is the instance name supplied using the [SIM_INSTANCE_NAME](#) parameter.

```
set_context patterns -ijtag  
read_design my_chip -view interface  
set_current_design my_chip
```

```
add_clocks clk -period 9.5ns
```

```
set_system_mode analysis
```

```
# This section contains a Verilog code block that is processed by the  
# Tcl "string map" command to replace `(id)`, `(path)` and `(period)` by  
# specific values. See string map usage in the check_lock iProc below.
```

```
set check_clock_string {  
  real clock`(id)_edge1_time, clock`(id)_edge2_time,  
    measured_clock`(id)_period;  
  event check_clock`(id)_period;  
  
  always @(check_clock`(id)_period) begin  
    # Measure the realtime for the next two clock edges  
    @ (posedge dut.`(path)) clock`(id)_edge1_time = $realtime;  
    @ (posedge dut.`(path)) clock`(id)_edge2_time = $realtime;  
    measured_clock`(id)_period = clock`(id)_edge2_time -  
      clock`(id)_edge1_time;  
  
    # Increment the compare event counter  
    tb._compare_count = tb._compare_count + 1;  
    $timeformat(-9, 3, " ns", 10);  
    if (1.01*measured_clock`(id)_period < `(period) || \  
      0.99*measured_clock`(id)_period > `(period)) begin  
      # Increment the miscompare counter when the period is not within  
      # 1% of the expected period.  
      tb._compare_fail_count = tb._compare_fail_count+1;  
      $display(  
        " Clock '`(path)' has wrong period: expected %0t, actual %0t",  
        `(period), measured_clock`(id)_period  
      );  
    end else begin  
      $display(" Clock '`(path)' has expected period of %0t",  
        measured_clock`(id)_period  
      );  
    end

insert_test_logic

Context: dft -scan, dft -test_points

Mode: analysis

Inserts the test structures you define into the netlist and stitches up the scan chains to increase the design's testability.

Usage

Context: dft -test_points

```
insert_test_logic [-verbose]
  [-write_in_tsdb { on | off | auto }]
  [-design_identifier design_identifier]
  [-write_insertion_script script_filename [-replace]]
  [-insertion [dc | genus]]
```

Context: dft -scan

```
insert_test_logic [-verbose] [-write_in_tsdb { on | off | auto }]
  [-design_identifier design_identifier]
```

Context: dft -scan -test_points

```
insert_test_logic [-verbose]
  [-write_in_tsdb { on | off | auto }]
  [-design_identifier design_identifier]
  [-write_insertion_script script_filename [-replace]]
```

Description

Inserts the test structures you define into the netlist and stitches up the scan chains to increase the design's testability.

The tool inserts test structures into a design to increase the fault coverage (testability) of the design. Specifically, the tool attempts to increase a design's fault coverage with the `insert_test_logic` command by doing the following:

- Identifies sequential cells and replaces them with corresponding scan cells, and stitches them together into a scan chain. (Referred to as scan cell replacement and stitching.)
- Supports the adding of both system-defined and user-defined test points.
- Supports the automatic adding of test logic.

For more information on scan replacement, test points and test logic, refer to [Test Point Analysis and Insertion](#) in the *Tessent Scan and ATPG User's Manual*. For information about handling pre-inserted scan cells, refer to "[How to Specify Existing Scan Cells](#)" in the *Tessent Scan and ATPG User's Manual*.

You can also use the `insert_test_logic` command with the `-write_insertion_script` switch to generate insertion scripts for test points for Design Compiler (DC) or RTL Compiler (RC). For more information, see “[How to Insert Test Points and Perform Scan Stitching Using Third-Party Tools](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- `-verbose`

An optional switch that specifies to the tool to output detailed information when the command is unsuccessful.

- `-write_in_tsdb on| off| auto`

An optional switch and literal pair that controls whether the extracted ICL is automatically written out in the specified TSDB output directory.

The `auto` value means “on” when the directory returned by `get_tsdb_output_directory` already exists, otherwise `auto` means “off.”

When set to “on,” the DFT inserted design is written out into the following directory:

```
tsdb_output_directory/dft_inserted_designs/  
module_name_design_id.dft_inserted_design
```

The `design_id` value is the one returned by `get_context -design_id`. See the `dft_inserted_designs` section of the [Tessent Shell Data Base \(TSDB\)](#) chapter for more information. If you have an elaborated ICL view in memory, it is exported to the new DFT inserted design directory with an updated `tessent_design_id` attribute value matching the current design id. The concatenated PDL file is also copied from its original source.

When the tool has completed writing the design to the TSDB, it reads the ICL variants from the original DFT-inserted design subdirectory. All the variants are updated and written to the new DFT-inserted design subdirectory alongside the default ICL file.

- `-design_identifier design_identifier`

An optional switch and value pair that sets the `design_identifier`.

Note

This switch is ignored if you have previously set the `design_identifier` using the “`set_context -design_identifier string`” command.

- `-write_insertion_script script_filename`

An optional switch that enables the tool to generate the script for inserting test points for Design Compiler (DC) or Genus™ Synthesis Solution. In the combined “`dft -scan -test_points`” context, you must run the “`set_insert_test_logic_options -generate_third_party_script`” command in Setup mode before running the “`insert_test_logic -write_insertion_script`” command.

insert_test_logic

- -replace

An optional switch that specifies to replace the output file generated by the insertion script, if the file already exists.

This switch is only available when also using the -write_insertion_script switch.

- -insertion dc | genus

An optional switch that specifies the target insertion tool of the insertion script.

dc — Generates the script for the Design Compiler (DC). This is the default.

genus — Generates the script for Genus Synthesis Solution.

This switch is not available in combined “dft -scan -test_points” context, where you can specify the target insertion tool using the “set_insert_test_logic_options -generate_third_party_script” command.

intercept_connection

Context: dft

Mode: insertion

A command that uses the `get_dft_cell` command to obtain a cell with the specified function name and uses it to intercept a connection to a pin, port, or net.

Usage

```
intercept_connection node -cell function_name function_name
  [-technology dft_cell_selection_name]
  [-input2 input2_source] [-select select_source]
  [-leaf_instance_prefix prefix_name]
  [-only_when_has_functional_source]
```

Description

A command that uses the `get_dft_cell` command to obtain a cell with the specified function name and uses it to intercept a connection to a pin, port, or net.

This command performs interception inside both uniquified and not uniquified modules.

Arguments

- **node**

A required value that is either a port, pin, or net name in the design or a collection of one port, pin, or net object. Based on the type of object and its direction attribute, in the case of a pin or a port, the source or destination connection of the object is intercepted.

[Table 4-26](#) shows the interception that is performed based on the node type. Note that an error is generated if the node is an inout pin or port, or if the node is a net corresponding to an inout pin or port.

Table 4-26. Interception Based on Node Type

Node Type	Interception Done	Illustration
Input port	The node is a driver. The intercepting cell ends up between the input port and its original fanout.	

Table 4-26. Interception Based on Node Type (cont.)

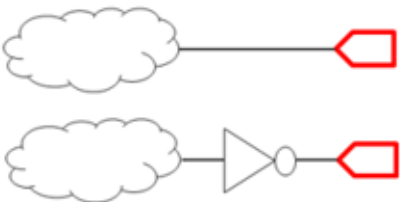

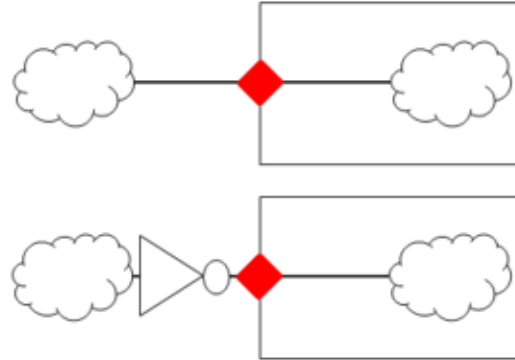

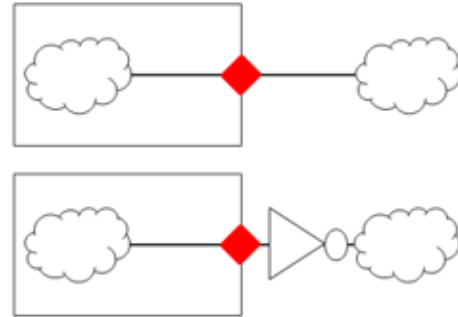

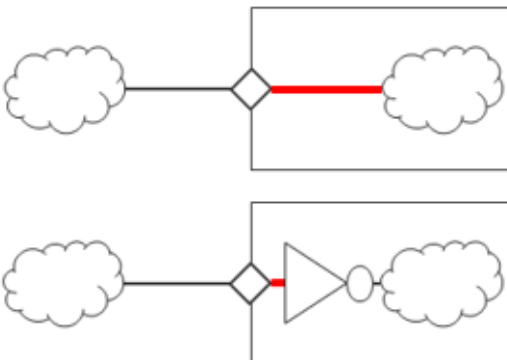

Node Type	Interception Done	Illustration
Output port	The node is a sink. The intercepting cell ends up between the original fanin and the output port	<p>Before and after interception:</p> 
Input pin	The node is a sink. The intercepting cell ends up between the original fanin and the input pin	<p>Before and after interception:</p> 
Output pin	The node is a driver. The intercepting cell ends up between the output pin and its original fanout.	<p>Before and after interception:</p> 
Net corresponding to an input pin or an input port	The node is a driver. The intercepting cell ends up between the input pin or port and its original fanout.	<p>Before and after interception:</p> 

Table 4-26. Interception Based on Node Type (cont.)

Node Type	Interception Done	Illustration
Net corresponding to an output pin or an output port	The node is a sink. The intercepting cell ends up between the original fanin and the output pin or port.	<p>Before and after interception:</p>
Net not corresponding to a pin or a port	The node is a driver. The intercepting cell ends up between the driver of the net and its original fanout. Only single driver nets can be intercepted.	<p>Before and after interception:</p>

- **-cell_function_name function_name**

A required switch and string pair that specifies the function of the cell to be used for the interception. [Table 4-27](#) shows the permitted cell function names and how the cell function affects the need to specify the -input2 and -select options.

Table 4-27. Permitted Cell Function Names

Function Name	Results
and	The interception is performed with the 2 input AND cell returned by the “get_dft_cell and” command. The -input2 option is required to specify the source of the second input. In the <i>Tessent Cell Library Manual</i> , see AND Cells for more details about the “and” cell_type and Cell Selection to know how to control which AND cell is used based on the specified -technology option.
buffer	The interception is performed with the BUFFER cell returned by the “get_dft_cell buffer” command. In the <i>Tessent Cell Library Manual</i> , see Buffer and Input Pad for more details about the “buffer” cell_type and Cell Selection to know how to control which BUFFER cell is used based on the specified -technology option.

Table 4-27. Permitted Cell Function Names (cont.)

Function Name	Results
inverter	The interception is performed with the INVERTER cell returned by the “get_dft_cell inverter” command. In the <i>Tessent Cell Library Manual</i> , see Inverter for more details about the “inverter” cell_type and Cell Selection to know how to control which INVERTER cell is used based on the specified -technology option.
mux	The interception is performed with the MUX cell returned by the “get_dft_cell mux” command. The -input2 and -select options are required to specify the source of the second data input and the select input. In the <i>Tessent Cell Library Manual</i> , see MUX Cell for more details about the “mux” cell_type and Cell Selection to know how to control which MUX cell is used based on the specified -technology option.
or	The interception is performed with the 2 input OR cell returned by the “get_dft_cell or” command. The -input2 option is required to specify the source of the second input. In the <i>Tessent Cell Library Manual</i> , see OR Gate for more details about the “or” cell_type and Cell Selection to know how to control which OR cell is used based on the specified -technology option.
clock_and	The interception is performed with the 2 input clock AND cell returned by the “get_dft_cell clock_and” command. The -input2 option is required to specify the source of the second input. In the <i>Tessent Cell Library Manual</i> , see AND Cells for more details about the “clock_and” cell_type and Cell Selection to know how to control which AND cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library. If one of the inputs has the function clock_in, it is selected for the interception.
clock_buffer	The interception is performed with the clock BUFFER cell returned by the “get_dft_cell clock_buffer” command. In the <i>Tessent Cell Library Manual</i> , see Buffer and Input Pad for more details about the “clock_buffer” cell_type and Cell Selection to know how to control which BUFFER cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library.
clock_inverter	The interception is performed with the clock INVERTER cell returned by the “get_dft_cell clock_inverter” command. In the <i>Tessent Cell Library Manual</i> , see Inverter for more details about the “clock_inverter” cell_type and Cell Selection to know how to control which INVERTER cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library.

Table 4-27. Permitted Cell Function Names (cont.)

Function Name	Results
clock_mux	The interception is performed with the MUX cell returned by the “get_dft_cell clock_mux” command. The -input2 and -select options are required to specify the source of the second data input and the select input. In the <i>Tessent Cell Library Manual</i> , see MUX Cell for more details about the “clock_mux” cell_type and Cell Selection to know how to control which MUX cell is used based on the specified -technology option.
clock_or	The interception is performed with the 2 input clock OR cell returned by the “get_dft_cell clock_or” command. The -input2 option is required to specify the source of the second input. In the <i>Tessent Cell Library Manual</i> , see OR Gate for more details about the “clock_or” cell_type and Cell Selection to know how to control which OR cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library. If one of the inputs has the function clock_in, it is selected for the interception.
	<ul style="list-style-type: none"> • -technology <i>dft_cell_selection_name</i> An optional switch and value pair that specifies from which dft_cell_selection list the cell is to be used. You only need to specify this option if your library has more than one dft_cell_selection wrapper. If you have none, one is learned for the simple cell types, but you have no access to the clock cells unless you have set their cell_type attribute in the library. See “Model-Level Attribute Descriptions” in the <i>Tessent Cell Library Manual</i> for information on how to specify the cell_type attribute. • -input2 <i>input2_source</i> An optional switch that specifies a node to connect to the second input of the cell. The source must be a valid pin, port, or net object, or a name, or the constant value 0 or 1. You should use a constant value if you want to insert a gate now and then connect the extra pins at some later time. Table 4-27 on page 1261 describes which values for -cell_function_name makes the specification of this option mandatory. • -select <i>select_source</i> An optional switch and value pair that specifies a node to connect to the select input of the cell. The source must be a valid pin, port, or net object, or a name, or the constant value 0 or 1. You should use a constant value if you want to insert a gate now and then connect the extra pins at some later time. Table 4-27 describes which values for -cell_function_name make the specification of the -select option mandatory. • -leaf_instance_prefix <i>prefix_name</i> This optional switch and value pair specifies the prefix to used when instantiating the cell. When this is not specified, the default is “insertion_”. The leaf instance name is constructed by concatenating the prefix_name with the cell_function_name. When a conflict is detected during instantiation, the tool automatically adds a “_<int>” suffix to uniquify the leaf name.

intercept_connection

You can use a specific prefix if you want to easily find the inserted cells in a synthesis or layout script by using a command such as “`get_cells prefix_name -hier`”.

- `-only_when_has_functional_source`

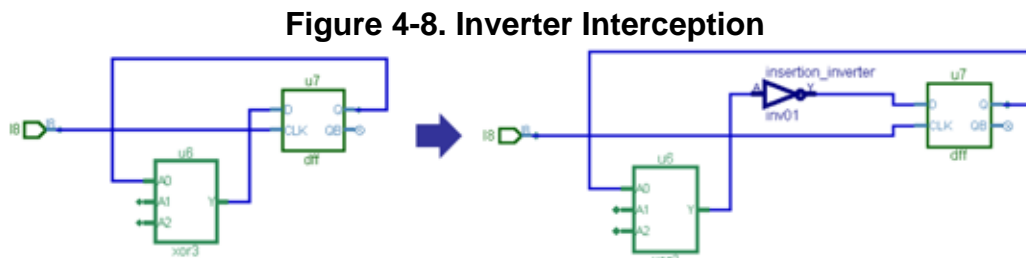

This optional switch specifies to skip the instantiation of the cell and interception of the node when the attribute `has_functional_source` is 0 for the node. Instead, the node is disconnected and driven by the specified `-input2` value. You cannot specify this option when `-cell_function_name` refers to a single input cell as there is no `-input2` value to connect to in that case.

Examples**Example 1**

The following example inserts a simple inverter gate by intercepting the existing connection between the `u7/D` pin and the `u6/Y` pin, shown on the left side of [Figure 4-8](#). After the interception, the inverter `A` pin is connected to the `u6/Y` pin and the inverter `Y` pin is connected to the `u7/D` pin as shown on the right side of [Figure 4-8](#).

```
INSERTION> intercept_connection u7/D -cell_function_name inverter
```

```
{insertion_inverter}
```

**Example 2**

The following example inserts a multiplexer and specifies to connect the second multiplexer input pin to 1, and to connect the multiplexer select pin to `scan_en`.

```
INSERTION> intercept_connection u4/u3/D -cell_function_name mux -input2 1 \
            -select scan_en
```

```
{u4/insertion_mux_1}
```

This example does the same thing as first example above but specifies the `-only_when_has_functional_source` option. Because this option is specified, the tool connects the pin `u1/u3/D` directly to a constant 1 if its `has_functional_source` attribute evaluates to 0. In this case, the command returns null as no intercepting cell was instantiated.

```
INSERTION> intercept_connection u4/u3/D -cell_function_name mux -input2 1 \
            -select scan_en -only_when_has_functional_source
```

```
{}
```

Example 3

The following example script shows how to cascade three gates on a set of nodes. The example illustrates how the command is capable of handling non-unique designs. The script works whether module “rep3” is unqualified or not. Note how the example inserts the first gate level on all nets, and then adds two more levels in a row on each net. This illustrates that it does not matter if you insert all gate levels on each net or if you add one level at a time. In both cases, the result is identical.

Original design:

```
module ex (ina, outa, c1, c2, c3);
  input c1, c2, c3;
  input [3:0] ina;
  output [3:0] outa;
  rep3 rep3_0 (.ina(ina[0]), .outa(outa[0]));
  rep3 rep3_1 (.ina(ina[1]), .outa(outa[1]));
  rep3 rep3_2 (.ina(ina[2]), .outa(outa[2]));
  repl repl (.ina(ina[3]), .outa(outa[3]));
endmodule
module rep3 (ina, outa);
  input ina;
  output outa;
  assign outa = ina;
endmodule
module repl (ina, outa);
  input ina;
  output outa;
  assign outa = ina;
endmodule
```

The dofile:

```
set nets [get_nets -of_pins [get_pins -direction input]]
foreach_in_collection net $nets {
  intercept_connection $net -cell or -input2 c1}
foreach_in_collection net $nets {
  foreach var {2 3} {
    intercept_connection $net -cell [lindex {and or} [expr $var-2]] \
      -input2 c$var -leaf_inst_prefix myprefix_
  }
}
```

The modified design:

```
module ex (ina, outa, c1, c2, c3);
  input c1, c2, c3;
  input [3:0] ina;
  output [3:0] outa;
  rep3 rep3_0 (.ina(ina[0]), .outa(outa[0]), .c1(c1), .c2(c2), .c3(c3));
  rep3 rep3_1 (.ina(ina[1]), .outa(outa[1]), .c1(c1), .c2(c2), .c3(c3));
  rep3 rep3_2 (.ina(ina[2]), .outa(outa[2]), .c1(c1), .c2(c2), .c3(c3));
  rep1 rep1 (.ina(ina[3]), .outa(outa[3]), .c1(c1), .c2(c2), .c3(c3));
endmodule
module rep3 (ina, outa, c1, c2, c3);
  input ina;
  output outa;
  input c1, c2, c3;
  wire c1, c2, c3;
  wire ina_ts1, ina_ts2;
  OR210 insertion_or(.A(ina_ts1), .B(c1), .Y(outa));
  AN210 myprefix_and(.A(ina_ts2), .B(c2), .Y(ina_ts1));
  OR210 myprefix_or(.A(ina), .B(c3), .Y(ina_ts2));
endmodule
module rep1 (ina, outa, c1, c2, c3);
  input ina;
  output outa;
  input c1, c2, c3;
  wire c1, c2, c3;
  wire ina_ts1, ina_ts2;
  OR210 insertion_or(.A(ina_ts1), .B(c1), .Y(outa));
  AN210 myprefix_and(.A(ina_ts2), .B(c2), .Y(ina_ts1));
  OR210 myprefix_or(.A(ina), .B(c3), .Y(ina_ts2));
endmodule
```

iOverrideScanInterface

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the [open_pattern_set](#) command. In the “dft”, “patterns -scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “[IJTAG and ATPG in Tessent Shell](#)” in the *Tessent IJTAG User's Manual*.

Imposes user-specified behavior on the operation of a ScanInterface.

Usage

```
iOverrideScanInterface scan_interface_list [-capture {on | off}] [-update {on | off}]  
[-broadcast {on | off}]
```

Description

Imposes user-specified behavior on the operation of a ScanInterface.

The iOverrideScanInterface command imposes user-specified behavior on the following three aspects of the operation of a ScanInterface:

- Whether or not it permits the capture of new data into the scan registers connected to that interface.
- Whether or not it permits the update of new data shifted into the scan registers connected to that interface.
- Whether or not it participates in scan broadcasting.

Arguments

- *scan_interface_list*

A required list of ICL ScanInterfaces to which the following settings apply. Only ordinary ScanInterfaces are permitted, no TAP ScanInterfaces, because the TAP state machine does not permit omitting the Capture-DR/Capture-IR cycle or the Update-DR/Update-IR cycle.

To be able to turn off the capture or update functionality on a ScanInterface of an internal instrument, the corresponding CaptureEnPort or UpdateEnPort of the ScanInterface need to be suppressible through a DataMux. The IJTAG engine automatically performs the necessary operations to suppress the capture or update enable signal before the operations of the next iApply.

- -capture {on | off}

An optional switch and literal pair that specifies whether or not the affected scan registers capture data from their parallel inputs, that is, from their specified CaptureSource. If this switch is set to off, the retargeting software ensures that the affected registers cannot be used

to observe iRead targets on their parallel inputs. Either a different possibility to observe the target can be found or the retargeting software issues an error message.

The “affected registers” are those registers that are on the path between the ScanInPort of a specified client ScanInterface and the corresponding ScanOutPort of that ScanInterface.

At startup time, the capture functionality is switched on for all scan interfaces. This default setting is reapplied by the iReset command and when a pattern set is opened without the -no_initial_ireset switch.

- -update {on | off}

An optional switch and literal pair that specifies whether or not the affected scan registers pass on their serially loaded data to their parallel outputs. If this switch is set to off, the retargeting software ensures that the affected registers cannot be used to justify a certain value at their parallel outputs. Either a different possibility to justify the value can be found, or the retargeting engine issues an error message.

At startup time, the update functionality is switched on for all scan interfaces. This default setting is reapplied by the iReset command and when a pattern set is opened without the -no_initial_ireset switch.

- -broadcast {on | off}

An optional switch and literal pair that indicates to the IJTAG retargeting engine whether the affected broadcast group (as described in the IEEE 1687-2014 standard) is activated or deactivated.

In an IJTAG network that supports broadcast, two steps are necessary to utilize its broadcast functionality. First, the network needs to be configured into the correct state for broadcast, for example, through an iProc command. Secondly, you must run the “iOverrideScanInterface -broadcast on” command to inform the IJTAG engine about the active broadcast group. This command requires the list of Scan Interfaces considered as a broadcast group. The IJTAG engine then keeps track of the network state in all broadcast locations to know the current state for later reference.

The [ICLNetworkVerify](#) patterns do not exercise or verify the IJTAG broadcast feature. Therefore, test patterns that utilize IJTAG broadcast must be simulated with care to ensure that the hardware implementation matches the implied behavior when using this switch.

Broadcasting conforms to IEEE 1687-2014, except Tessent does not impose the rule that you must identify each scan interface in the AllowBroadcastOnScanInterface list in the ICL of the associated ICL instance.

You must enable broadcast mode by running the “iOverrideScanInterface -broadcast on” command, because the retargeting software does not do it for you. Broadcast mode remains in effect until you turn it off by running “iOverrideScanInterface -broadcast off”. When broadcasting, the command should contain only a list of scan interfaces having ScanInPort sharing a common source. You should configure multiplexers in the path between the common source and the ScanInPorts to select the path to a common source in the scan chain.

Broadcasting involves one target scan interface and one or multiple shadow scan interfaces. All scan registers behind the scan interfaces receive a copy of the scan data. A broadcast group's hardware implementation must activate all the scan interfaces' select ports when the target interface is on the active scan path. The scan chain behind an active target interface must be longer or equal in size to all other scan chains behind the other scan interfaces.

The retargeting software assigns the broadcast values during each scan load. The number of bits always matches the number of bits in the currently active scan path in the target Scan Interface.

Return Values

None.

Examples

The following example turns off capture on scan interface client1:

```
iOverrideScanInterface client1 -capture off
```

The following example turns off update on two scan interfaces:

```
iOverrideScanInterface c2 c3 -update off
```

iPDLLevel

Context: all contexts

Mode: all modes

Identifies the level and version of PDL commands.

Usage

iPDLLevel *level* [-version *version*]

Description

Identifies the level and version of PDL commands.
